WE have been cutting Early April since the end of March, and nice little developed heads, too. One or two varieties have bolted rather badly, but we are using the greens and then pulling up the plants and replacing with some fresh stock which has been pushed along in frames, and which will make a fine succession. In order to always have some nice young Cabbage it is a good plan to sow some of the summer varieties about every month from March to June or July. Sutton's Flower of Spring is a good variety to follow Early April, and is a Cabbage of much merit. Carter's Early Heartwell is another Cabbage of exceedingly fine quality, and one of the very best in cultivation. Carter's Beefheart is also a splendid Cabbage, probably one of the finest grown. It is, moreover, very hardy as well as robust, and when a large Cabbage is wanted, this is the one to grow. These are, of course, August-sown Cabbages. Good varieties to sow now are Sutton's Favourite, Earliest, Tender and True, and Sutton's All Heart. Sown now and onwards, these make very dainty dishes through the summer months, and are always welcome. These can be put in as catch-crops to fill up the ground where early crops have been gathered, and such crops do not take much out of the soil, as the longest time they are on it is not many months. I like to see the ground occupied rather than lying dormant. We have to crop nearly all our ground twice and thrice in a year, as far as is at all practicable.

The Gardens, Leonardslee. W. A. Cook.

NEW AND RARE PLANTS.

FIRST-CLASS CERTIFICATES.

Odontoglossum Uro-Skinneri Burford Variety.

—A handsome variety, remarkable for its depth of colour and exceedingly broad lip. The plant shown was of robust habit and carried a strong spike of large flowers. Shown by Sir Trevor Lawrence, Bart.

Cattleya Schroderæ Glebelands.—A fine variety of a well-known Cattleya. Its most noteworthy feature lies in the exceptionally large chrome yellow zone in the lip of the flower. The petals are very pale mauve, almost white. Shown by J. Gurney Fowler, Esq.

AWARDS OF MERIT.

Cheiranthus mutabilis Keeley's Variety.

—A plant of decided merit and freedom of flowering. As shown the examples were much dwarfer and bushier than the type, and with deeper-toned flowers, reddish in the main, though variable, as the name suggests. From Mr. W. Rickards, Ask Priory.

Echium truncatum.—A fine companion to such giants of the race as *E. Wildpretii*. The columnar spicate inflorescences are very large, the flowers of an intense gentian blue, and rendered the more attractive by the long protruding stamens, which are of a reddish colour. The species requires the protection of a warm greenhouse. It is very handsome and well deserves extensive cultivation.

Celsia cretica Cliveden Variety.—A very showy variety of this useful plant. The flowers are of clear yellow colour, figured with crimson at the base of the upper petals, and are disposed

in dense spicate racemes. These came from W. Astor, Esq., M.P., Cliveden, Taplow (gardener, Mr. W. Camm).

Cineraria Pompadour (Strain).—We presume we are entitled to regard this as a fancy strain, inasmuch as in all the variations of it there is a marked tendency to colour variation in the florets. The dominating colours are blue, white and rose, and these occur in longitudinal stripes on the florets with a good deal of regularity. As shown the plants were very dwarf and exceedingly pretty. From Messrs. James Veitch and Sons, Limited, Chelsea.

Lewisia Howellii.—A superbly-flowered example of this recently-introduced novelty was shown. The succulent leaves are nearly spatulate, with raised, crested, sinuate margins, the stalked inflorescences appearing from the bases of the lower leaves. The plant carried about eleven finely-developed inflorescences and a profusion of flowers capable of enduring for weeks. The expanded flowers are of the size of a shilling, buff to apricot in tone and striped with red. By far the most remarkable alpine novelty shown at this meeting. Exhibited by Mr. M. Prichard, Christchurch, Hants.

Deutzia longifolia.—A delightful novelty and a good garden plant all in one; a plant, too, that must presently be demanded in its thousands. The great charm of the species is the pink colouring of the flowers, these appearing in axillary clusters on every twig and branch, large or small. Bushy and free in growth and flowering, and neat-habited and hardy withal, the new-comer would appear to possess every attribute capable of rendering it immensely popular. It is one of Mr. Wilson's introductions from China, and we regard it as an acquisition. Exhibited by Miss Willmott, V.M.H., Warley Place, Essex.

Saxifraga Mrs. J. F. Tottenham.—A most charming hybrid kind—presumably *S. granulata* and a Mossy variety. The buds are at first pink coloured, and on expansion reveal a pure white surface. Quite a good novelty belonging to a new and highly attractive race of Saxifragas. (See illustration on page 232).

Saxifraga Comet.—Also a *granulata* hybrid, the evidence being well marked in the leafage. Indeed, if the root characteristics of *S. granulata* remain, it might prove but a glorified form of that well-known kind. The flowers are very large, rather starry and pure white. Both were exhibited by Mrs. Lloyd-Edwards, Llangollen.

Araucaria excelsa elegantissima aurea.—In the small examples as shown this is a very pretty variety, the tips of all the branchlets being of a pale yellow colour, which is in marked contrast to the body colour of the branches. As an excellent companion to Silver Star, which has whitened or silvery tips, we commend this fine novelty to all. From Messrs. Thomas Rochford and Sons, Broxbourne.

Tulip Velvet King.—A very handsome Darwin kind of deep bronzy red colour. From Messrs. Barr and Sons, Covent Garden.

Tulip Grenadier.—A May-flowering sort of the largest size. The dominant colour shade is orange scarlet; internally the flowers have a clear golden base. Exhibited by Messrs. Walter Ware, Limited, Bath. The stock of this fine Tulip has passed into the hands of Messrs. Wallace and Co., Colchester.

The foregoing were shown before the Royal Horticultural Society at Vincent Square, Westminster, on April 30, when the awards were made.

ANSWERS TO CORRESPONDENTS.

RULES FOR CORRESPONDENTS.

QUESTIONS AND ANSWERS.—The Editor intends to make THE GARDEN helpful to all readers who desire assistance, no matter what the branch of gardening may be, and with that object will make a special feature of the "Answers to Correspondents" columns. All communications should be clearly and concisely written on one side of the paper only, and addressed to the EDITOR OF THE GARDEN, 20, Tavistock Street, Covent Garden, London, W.C. The name and address of the sender are required in addition to any designation he may desire to be used in the paper. When more than one query is sent, each should be on a separate piece of paper. Plants for naming should be clearly numbered and securely packed in damp grass or moss, not cotton-wool, and flowering shoots, where possible, should be sent. It is useless to send small scraps that are not characteristic of the plant. Letters on business should be sent to the PUBLISHER.

FLOWER GARDEN.

PRIMROSES DYING (Rhaqat).—With the meagre evidence afforded, it would be but the merest guesswork for us to say what insect was the cause of the mischief. We advise you, however, to search for slugs at dusk, and dust the plants with soot. Not infrequently birds in their search for nesting material play havoc with these plants. Usually, however, it is the winter work of the slug.

TALL HERBACEOUS PERENNIALS (E. E.).—You would find the Michaelmas Daisies among the more useful, and from two or three sections you might select all that you would require. In case you wish for greater variety, we give you names: Aster Climax, A. Novi-Belgi Wm. Marshall, A. N.-B. Robert Parker, A. N.-B. Beauty of Colwall, A. N.-B. Arcturus, A. Nova-Angliae Mrs. S. T. Wright, A. cordifolius Edwin Beckett, A. c. Ideal, and A. c. elegans. These embrace three sections of the Michaelmas Daisies. Other good things are Helianthus Mrs. Moon, H. multiflorus giganteus, H. m. major, H. m. fl.-pl. Helenum autumnale grandicephalum, H. orgyalis, Pyrethrum serotinum, Bocconia cordata, Hollyhocks, Heliopsis scabra, Solidago Shortii and S. multiradiata. If space permits of leaf development, Anemone japonica in red, pink and white might well be included.

DAFFODILS (E. W.).—The Lenten Daffodils (*Narcissus pseudo-Narcissus*) you kindly forward for our inspection are just a good ordinary sample of this wilding when growing in congenial soils and amid congenial surroundings. The plant simply luxuriates in moist meadow lands, and as these more nearly approximate to mellow clay, the finer do the flowers become. Where the soils are inclined to be of a reddish clay, there do we usually find a little more external coloration, just as those inhabiting drier and lighter soils are seen to be of a much paler tint. It is all a question of environment, and flowers of the character and good quality you submit are common to Warwick, Worcester, Devon and Sussex. It may be that the residue from the works near by, acting as a tonic, is responsible for a little of the colouring, though the soil and marshy nature may be responsible for much more.

TREES AND SHRUBS.

TREATMENT OF A YEW HEDGE (Bede).—It would help your Yew hedge to thicken at the bottom if you were to cut 6 inches or 9 inches off the top. It will, however, take a very long time to get the lower part well furnished with branches. Should there be sufficient space between the plants, it would be a good plan to interplant with nice young, bushy plants. These in time would spread out and furnish the bottom. If you gave the ground along each side of the hedge a top-dressing of well-decayed manure, it might assist the roots somewhat and cause stronger shoots to be made.

SHRUB FOR NAME AND TREATMENT (F. S.).—The specimen of a variegated-leaved shrub sent for identification is *Euonymus radicans foliis roseo-argenteis*. It ought not to be difficult to propagate. Try taking cuttings of short shoots in June or July, and insert them firmly in pots of sandy soil in a close frame. Water carefully until rooted. Roots ought to be formed in about three weeks' time after the insertion of the cuttings. The Cornish Elm is planted less frequently than it ought to be as a street tree. The leaf you send for name is the Fern-leaved Beech (*Fagus sylvatica* variety *heterophylla*). Fine examples of it are to be found in various parts of the country.

CONE FOR IDENTIFICATION (A. M. D.).—The cone sent for name belongs to the Cluster Pine (*Pinus Pinaster*), a native of the Mediterranean region. If your Pines are growing close together, you cannot expect shrubs to do well beneath their shade; but if there are moderately large open spaces, you could make an effective undergrowth by using evergreen and deciduous Rhododendrons, with patches of Heather and hardy Ferns here and there. The Laurels might be cut down almost to the ground at the present time. All the stumps may not grow again, but the majority ought to form nice bushy plants from new branches produced from dormant buds. You cannot expect much in the way of shrub growth beneath the shade of a large Beech tree. We advise you to plant the ground beneath the tree with Bluebells and Ferns.

THE GREENHOUSE.

ORCHIDS IN A VINERY (N. G.).—There are several Orchids that will thrive in a vinery, provided those selected make their growth during the summer months and are at rest the same time as the Vines. We suggest that you commence with a few plants, such as *Dendrobium nobile* and its varieties *alba* and *nobile*, *D. Ainsworthii*, *D. Wiganii*—in fact, any member of this useful genus; *Laelia anceps* and its various forms known as *chamberlainiana*, *Stella*, *alba*, *Dawsonii* and *sanderiana*. If your house is a lean-to, *Epidendrum radicans*, *xanthinum*, *obrienianum*, *Bouindii* and *kenwense* could be planted against the wall, while such subjects as *Calanthe Veitchii*, *Harrisii* and *William Murray*, also any of the *Catasetums*, would thrive on a shelf about two feet from the roof glass or on the staging beneath the Vines. The chief points in cultivation are to repot when new roots appear at the base of the current growth, using pots just large enough to comfortably take the roots, and allowing sufficient space for one or two seasons' growth. The soil should be clean, live sphagnum moss, good peat and *Osmunda* fibre in equal parts; but for the *Calanthes* and *Catasetums* fibrous loam should be employed instead of the *Osmunda* fibre. Fill the pots one-third of their depth with drainage, and press the soil moderately firm about the base, while the watering must be carefully done at all times. All the plants ought to be kept near the glass. This can be done by means of inverted flower-pots. Orchids have few pests, the worst being thrip, which can be easily kept in check by vaporising the house occasionally; but a sharp look-out must be kept for red spider if it is present on the Vines. We take it your vinery is heated, otherwise it would be useless to attempt Orchid-growing.

FRUIT GARDEN.

CHERRY BLOSSOM REFUSING TO OPEN (G. L. C.).—The branch of Cherry tree with flower-buds on is suffering from a disease termed canker. It is the disease to which, unfortunately, the Cherry tree, like the Apricot, is subject. That part of the tree from where this branch is taken will probably die in the course of the summer or autumn. There is no cure for the disease; but trees slightly affected live to be old and bear good crops of fruit annually.

VINES DOING BADLY (W. M.).—The best thing to do is to lift the Vines as soon as the leaves have dropped in the autumn, overhauling the roots, cutting away the dead ones and shortening the points of all. Clear away all the old soil and see that the drainage is sufficient. Replant in the following compost: To one good barrow-load of turfy, fibrous loam add a gallon of brick ends, broken small (size of a pigeon's egg), the same of old mortar rubble, broken in the same way, three pints of quarter-inch bones and a pint of bone-meal, also a sprinkling of soot. Mix all well together, and have everything ready for replanting before the Vines are disturbed, so that the roots are not exposed longer than can be helped. It is better to lift the Vines entirely than to add more soil to the existing border as you suggest doing.

MISCELLANEOUS.

JAPANESE DWARF TREES (M. A. G. D.).—Japanese dwarf trees may be treated in the same manner as hardwooded, cold greenhouse plants. At all times of the year the soil should be kept moist, but never let it become thoroughly saturated, such as happens when a plant stands continually in water. Repotting is unnecessary, for, should you begin to be too generous to the plants, they will probably outgrow their dwarfed character.

NAME OF FRUIT.—F. T., Lytham.—The fruit was too far gone for us to be sure, but we believe it to be Cox's Orange Pippin.

NAMES OF PLANTS.—G. H.—Rose Catherine Mermet. —A. M.—1, *Daphne pontica*; 2, *Lotus Bertholletii*. —H. W. C.—Flowers insufficient for identification. —L. H.—*Lotus Bertholletii*. —W. J. B.—1, *Adiantum gracillimum*; 2, *Abutilon megapotamicum* var. *variegatum*; 3, *Phlox frutescens*; 4, *Convolvulus majalis* var. *rosea*. —Mrs. H. B.—1, *Narcissus Jonquilla*; 2, *Saxifraga granulata* flore pleno; 3, *Tiarella cordifolia*; 4, *Asperula odorata*; 5, *Waldsteinia fragarioides*; 6, *Saxifraga muscoides* Rhei; 7, *S. m. atropurpurea*; 8, *Iberis sempervirens*.

LEGAL POINT.

Outgoing Tenant: Fruit Trees (Drogheda).—The tenant of an ordinary residential property cannot sell or remove fruit trees, hedges, flowers, nor Box borders, although planted by himself, nor is he entitled to any compensation for them. Sometimes an incoming tenant takes over fixtures from an outgoing tenant at a valuation, and occasionally this is extended to the fruit trees and Rose bushes. If this is done, the incoming tenant should take care that the landlord is made a party to such an arrangement, otherwise they will vest in him at the close of the first tenancy. Any right of removal or compensation that exists is conferred on certain classes of tenants by statute, as on market-gardeners under the Agricultural

Holdings Act, when it has been agreed in writing that the holding should be treated as a market-garden, or on cottagers or allotment-holders. By the Allotments and Cottage Gardens Compensation for Crops Act, 1887, the tenant can obtain compensation from the landlord for crops, including fruit growing upon the holding, fruit trees and bushes planted by the tenant with the previous consent in writing of the landlord, and for labour expended and manure applied in anticipation of a crop. The land held is not to exceed two acres. There cannot be much doubt about what amounts to an allotment; but as the statute gives no definition of a "cottage," trouble may arise as to whether the tenant holds a "cottage garden."—BARRISTER.

SOCIETIES.

AURICULA SHOW AT SPARKHILL.

The first of a series of exhibitions organised by the Sparkhill Horticultural Society was held on April 27 at the St. John's Council Schools, Stratford Road. The exhibits consisted of Narcissi and Auriculas, and the various classes were well represented. The Auriculas were of excellent quality, displaying great care in cultivation, but owing to the date fixed for the show being rather late in the season, the display of Narcissi was not quite up to the usual standard.

The following were the prize-winners: Eight bunches of Narcissi, at least six distinct: First, Mr. E. J. Keeling. Most tasteful arrangement of Narcissi: First, Mr. E. J. Keeling; second, Mr. F. Anderson. Six bunches of Narcissi, at least four distinct: First, Mr. E. J. Keeling. Three bunches of Narcissi, distinct: First, Mr. E. J. Keeling; second, Mr. F. Anderson. Three named show Auriculas, distinct: First, Mr. H. J. Spencer; second, Mr. H. W. Miller; third, Mr. E. Saunders. Three named alpine Auriculas, distinct: First, Mr. H. W. Miller; second, Mr. H. J. Spencer; third, Mr. J. Freeman. Three seedling alpine Auriculas: First, Mr. H. W. Miller; second, Mr. J. Freeman; third, Mr. A. Gilbert. One seedling show Auricula: First, Mr. A. Gilbert; second, Mr. H. W. Miller.

Special classes, open to all comers: Three show Auriculas, named, distinct: First, Mr. G. Savory; second, Mr. J. Freeman; third, Mr. T. M. Eglinton. Three alpine Auriculas, named, distinct: First, Mr. J. Freeman; second, Mr. H. W. Miller; third, Mr. G. Savory. Mr. G. Savory was awarded the society's certificate for the premier Auricula in the special classes, and Mr. H. W. Miller the society's certificate for the premier Auricula in the members' classes. A bronze medal was gained by Mr. E. J. Keeling for the most points in the classes for Narcissi, and by Mr. H. W. Miller in the classes for Auriculas. A certificate was also presented to Mr. C. J. Fox for an exhibit of alpine blooms and other spring flowers.

THE NATIONAL AURICULA EXHIBITION.

WHATEVER may have been the opinions of the promoters on the merits of their exhibition at the Royal Horticultural Hall on the 30th ult., it certainly must have been disappointing to visitors. The table devoted to the show section, which comprises white, grey and green edged and self flowers, had a singularly dull and unattractive appearance, so many of the flowers being stale or otherwise indifferently developed. The corresponding table immediately opposite was, on the other hand, singularly bright with the beautiful gold or white centred alpines, the classes being better filled, showing that while these varieties are easier to grow, they further give much greater floral beauty in return for cultivation. The connoisseur in the shows must be something of an enthusiast over markings, edgings and other attributes; but the average lover of Auriculas admires them for their colour-beauty and undoubted charm, hence he turns to the alpines naturally.

Among edged shows, G. Lightbody, Aene, Fucharis, Richard Headley, Shirley Hibberd and Heatherbell (all old ones) were of the best; and of selfs, Mikado, Peggy Gordon, Harrison Weir, Mrs. Phillips and Victor (maroon crimson), this variety securing the premier award as the best show variety in the exhibition. In the classes for singles, Prince Charming, Rifleman and Shirley Hibberd were the best green edged; with greys, the old G. Lightbody and Richard Headley; with whites, Aene; and with selfs, Mikado (maroon) and Peggy Gordon (red). There were no seedlings worthy of notice. The fancy class brought two collections. The best of these flowers are the yellow selfs, which are charming. Canary Bird, Sunray and Maggie Burck were very bright. It is a pity a special class is not instituted for pure yellow selfs; then all other fancies could go to the rubbish-heap. It is well to notice that while florally the distinctions between shows and alpines are important, shows may be merely all over, but alpines must be quite devoid of merit.

In the alpine section there were five entries of twenty-four plants, thus showing how popular they are. Here, as was the case in all the open classes, Mr. James Douglas was a prominent prize-winner. In the class the most striking gold centres were Duke of York,

Golden Distinction, Majestic and Golden Eye; while white centres were Roxburgh, Argus, Robert Bruce and Prince of Tyre. In Messrs. Phillips and Taylor's second-prize group Mars was the premier gold-centred flower in the section. Others good were The Idol and Her Grace, and of whites Argus and several seedlings. In other classes Muriel, Charles Halcro, Chaucer, Dean Hole and Sunrise were good gold centres; and of whites Hene, Blue Bell, Lucrece and Phyllis Douglas. In single plants with gold centres, Muriel (a far better flower than Mars) was first, with Majestic second and third. Phyllis Douglas was the best white centre, with Prince of Tyre and Roxburgh following. Polyanthus of the border varieties, which usually make so conspicuous a feature in groups, baskets, or in pots, were practically absent, only nine small ones or Primroses being set up, and those were worthless. The *Primula* species were represented by one small basket of four kinds—*obconica*, *japonica*, *Sieboldii* and *malacoides*. How we sigh for the collections of those beautiful Primroses once shown in such profusion! Clearly the National Auricula Society wants some revival of its old glory, or else be quietly laid to rest. A further need is improved naming, as at present only labels are used, and those are buried behind the foliage.

* * * Owing to the demand made on our space by other subjects, we are compelled to hold over the report of the Midland Auricula Show. This will appear next week.

OBITUARY.

THOMAS JONES.

By the death of this gentleman there passes away, in his eighty-sixth year, one of the foremost of British gardeners of the older generation. For nineteen years he was head-gardener to Her late Majesty Queen Victoria at the Royal Gardens, Windsor and Frogmore, succeeding the late Mr. Rose in that position. Mr. Jones retired from the Royal service on a pension twenty-one years ago, and has since lived on a property he purchased at a pretty country village (Puttingham) near Wolverhampton. Here he passed away his time among surroundings congenial to his nature and to his life-long work, namely, gardening and farming (in a small way). Born at a farm in Denbighshire, North Wales, he never lost his love for farming, cattle, horses and dogs and all appertaining to that life always appealing strongly to his nature. As a gardener, possibly fruit and vegetable culture appealed to him more strongly than did other aspects of garden work, although in a garden of the extent and importance of that at Windsor all other aspects of practical gardening claimed and engrossed the whole of his time and care. Mr. Jones was a gentleman of strong personality and character. He was absolutely indifferent to the applause or the criticism of the world of gardening outside, content to pursue his own life in his own way. By strangers he was apt to be written down as a martinet, and of austere and uncompromising demeanour. But to those who knew him well he revealed himself as a genial, kind-hearted and most entertaining man. He was a gentleman who never spared himself, but gave his life wholly to his profession, earning and retaining the full confidence and appreciation of his Royal employer to the last. Mrs. Jones predeceased him by some years. They had no family. Previous to going to Windsor he had been head-gardener to Lord Leconfield at Petworth for many years.

"Country Life" for May 11 contains, among other articles, an illustrated account of "Buckhurst Park.—I."; "Tale of Country Life: Through—A Legend of Loch Gur," by Dorothy Conyers; "The Songs of Labour"; "On the Growth of Two Salmon" (illustrated), by J. A. Milne; "The Time of the Singing of Birds" (illustrated), by E. L. Turner; "British Birds and Their Observers."

EDITORIAL NOTICES.

Every department of horticulture is represented in **THE GARDEN**, and the Editor invites readers to send in questions relating to matters upon which they wish expert advice.

The Editor welcomes photographs, articles and notes, but he will not be responsible for their safe return. All reasonable care, however, will be taken, and where stamps are enclosed, he will endeavour to return non-accepted contributions.

As regards photographs, if payment be desired, the Editor asks that the price required for reproduction be plainly stated. It must be distinctly understood that only the actual photographer or owner of the copyright will be treated with.

*The Editor will not be responsible for the return of artistic or literary contributions which he may not be able to use, and the receipt of a proof must not be taken as evidence that an article is accepted. Publication in **THE GARDEN** will alone be recognised as acceptance.*

Offices. 20, Tavistock Street, Covent Garden, W.C.

NOTES OF THE WEEK.

Paulownia imperialis Flowering Outdoors.—

During the past week flowers of this beautiful tree have reached us from Devonshire and Somersetshire respectively. In one instance this is the first time the tree has flowered for twenty-five years. Possibly the excessive heat of last summer ripened the wood extra well, and thus induced the formation of flower-buds.

The Mountain Avens.—*Dryas octopetala* is a plant we do not too frequently see doing well in the rock garden, and in some soils it apparently refuses to grow and dwindles away. Some attribute this to want of moisture and peaty soil, but its real need is lime, and this should be supplied if the *Dryas* is to be really healthy and happy. We saw a very fine plant the other day in quite a dry place, which never thrived until it was supplied with plenty of lime. Then it began to thrive and grew apace, until it has formed a plant of exceptional beauty and size. It is more difficult to induce it to bloom as freely as on its native hills, and the plant referred to does not flower quite so well as is desired. It, however, produces a fair number of its fine white flowers. Sun and lime, with some peat in the compost, will do well for the Mountain Avens, which is so beautiful in or out of bloom.

An Interesting Chinese Honeysuckle.—The sunny summer of 1911 has been responsible for numerous shrubs flowering more freely than usual, and this is the case with several of the bush Honeysuckles. *Lonicera tatarica* is flowering with great freedom at Kew, and a large bush in the vicinity of the Ferneries is a mass of bloom. *L. tatarica* is a native of Siberia and North China, and grows into a bush 12 feet or 15 feet high and as far through. As is the case with other bushy species, the flowers are borne in pairs from the leaf-axils, and not in many-flowered heads as is usual with the trailing kinds. The flowers of the type are white or but faintly tinged with rose; but there are varieties which have pink and red blooms, two very good coloured kinds being *pulcherrima* and *punicea*. *L. tatarica* requires no elaborate cultivation, for given good garden soil it grows quickly. Ordinarily, plants are not more than half as well flowered as they are this year.

Double Wallflower Harpur-Crewe.—This old Wallflower, known long before the time of the revered flower-lover whose name it bears, is, as usual, doing well this season and is giving great quantities of its pleasing yellow flowers. It is not to be placed in the same plane as the double German Wallflowers, but is a much more delightful plant. This is said without any attempt to disparage the German Wallflowers, which are very

fine in their own way, but a good bush of Harpur-Crewe three or four years old will give a host of neat spikes of fragrant double yellow flowers, and is quite in place in a good border or on a rock garden. It is readily propagated by cuttings, and it is always desirable to have a few of these in case the old plants succumb to the winter, although this *Cheiranthus* is wonderfully hardy and long-lived. It does best on a dry and sunny place, and is always acceptable both for its beauty and for the exquisite fragrance.

The International Horticultural Exhibition.—

This exhibition, which is to be opened next Wednesday by His Majesty the King, promises to be the largest and best of its kind that has ever been held in this country, and will be an event that those who see it will, we hope, look back upon with considerable pleasure. But there will be many who, from some cause or another, will not be able to visit the exhibition; and in response to the wishes of a number of such readers, we shall next week publish a Special Double Number. This will contain a sixteen-page supplement, giving details of all the best things to be seen at the exhibition, as well as a number of illustrations prepared from photographs of the exhibits. Some interesting illustrations of Chelsea Hospital itself, together with a brief account of this historical home for pensioners of the British Army, will also be included. The price of this special issue will be twopence, and copies will be on sale at our kiosk in the exhibition grounds at Chelsea on Thursday afternoon, May 23. We shall be pleased to welcome any of our readers who care to call at this kiosk, which will be situated in the Central Avenue.

A Pretty New Fuchsia.—In the early part of last year a seedling Fuchsia was forwarded by a correspondent with a request for our opinion concerning it. At that time it struck us as an extremely pretty variety, an opinion strengthened by seeing some flowering examples in the winter. It was placed before the floral committee of the Royal Horticultural Society on April 30th by Messrs. W. H. Rogers and Son, Red Lodge Nursery, Southampton, but did not get an award. Still, we think that is bound to come if further shown. The name is *Benita*, and it is said to be the result of a cross between a Continental variety—*Gartenmeister Bonstedt*—and *F. splendens*. The flowers, which are borne in great profusion at the ends of the shoots, are about an inch long, and hang suspended by slender pedicels of the same length. The stout tube of the flower and the sepals, which, however, never reflex, are of a rosy scarlet colour, while the petals are of a bright orange scarlet. It is of a freely branching habit and flowers profusely. As *Gartenmeister Bonstedt* has resulted from the crossing and intercrossing of *F. triphylla*, *F. fulgens* and, perhaps, others, the variety *Benita* has in it the blood of at least three distinct species.

CORRESPONDENCE.

(The Editor is not responsible for the opinions expressed by correspondents.)

Hyacinths and Abutilons.—Seeing the photograph of Grand Maître Hyacinths at Hampton Court in THE GARDEN for April 27 prompts me to record that I saw the same variety of Hyacinth most effectively employed this season in a public garden as dot plants in a groundwork of the ordinary Jonquil. The latter was indeed a fine set-off for the large azure blue spikes. In THE GARDEN of May 4, page 219, "Avon" has an interesting article on Abutilons, but he makes no mention of their usage out of doors. In fact, he seems to imply indoor treatment only by suggesting a cool structure for the summer months. Some of the varieties at least make splendid summer bedding plants. Has he not tried any? Since living in North London I saw a variegated variety in use in a neighbouring garden. It may have been *Thompsonii*. At a former place—Eaton Hall, Chester—Abutilons were used in the summer beds. I particularly remember a variety with mottled leaves being used dotted among certain beds of *Violas*.—C. T.

Rosa Hugonis Flowering Early.—This delightful little Rose was in full bloom with me on May 6, seven days earlier than the first bloom opened last year. Excepting for a stray bloom of the common China and *Cramoie Supérieure*, this is the first-comer of the glorious Rose season which it ushers in. It is a lovely colour, a clear pale yellow, its single flowers being about one and a-half inches across and of cupped form. They are borne singly on short stalks the whole length of the growths, so that to prune this Rose would be to cut away its blooms. In growth it is unique, the prickles being of large size and the whole plant extremely pretty, even when not in bloom. There is a fragrance not unlike the Austrian Briars, only not so strong. Grown as a single bush upon the lawn in the centre of a bed of *Geum miniatum*, or, better still, of that marvellously rich-coloured *Geum Mrs. Bradshaw*, the effect would be delightful in the early May days.—W. EASLEA, *Eastwood, Essex*.

Potentilla Valderia.—With reference to Mr. Arnott's note on *Potentilla Valderia*, page 227, issue May 11, this plant, like *Viola Valderia*, takes its name from the *Bagni di Valdieri*, a charming health station of hot springs in the Gesso Valley on the north side of the Maritime Alps, immediately at the foot of the *Argentera*. The locality, besides its great beauty, is a very rich centre for plants, both *Saxifraga pedemontana* and *S. flornlenta* having stations close at hand. The *Potentilla* abounds in stony places by the river, especially about a quarter of a mile below the hotel. The true *Potentilla Valderia* is distinguished by foliage of an extraordinarily beautiful argentine effect, the three-lobed leaves being neither green nor variegated in any way, but as if actually cut out of silver. In Nature the plant is very robust and stalwart, attaining a height of some two feet; in cultivation it has with me always remained quite neat and dwarf. It also shows an extreme reluctance to flower, a fault, however, which one regrets the less in that the flowers, carried in tall, leafy cymes, are not up to the promise of the plant's foliage charm, having narrow white petals, between which appear the broad green sepals, giving the bloom a rather dingy effect.

Full notes and description of this species will be found in my "Among the Hills."—REGINALD FARRER.

Exhibiting Daffodils.—Mr. Jacob invites criticism of his selection of the best flowers at the Royal Horticultural Society's Daffodil show, page 220, issue May 4. The flowers he mentions as the best I also think were in "the first flight," but I do not agree with Mr. Jacob's idea of "placing." When you try to do so in the case of such dissimilar flowers as he describes, I think you attempt the impossible. If you say *Avalon* is the best of its class, one knows where one is; but to say that it is better than *Susan* (what a name!) is like saying a handsome brunnette is better than a lovely blonde! Let us call them first-class flowers of their respective divisions. In addition to the flowers Mr. Jacob mentions, there was a *Poeticus* on Mr. Engleheart's stand which subsequently appeared on Mr. Wilson's stand that I think was of its "class" a very fine thing, and seemed to run *Coronation* very close. It was very large and round, with a distinct red-rimmed eye of pleasing form. There were also two very fine flowers of their class shown by Mr. Crosfield, viz., *Dick Turpin* and *Mougle*, both flat-cupped *Barris* (with apologies to the framers of the list classification), petals very overlapping, of a creamy white, 3-inch spread, very serrated red orange eyes; much alike, but I thought *Dick Turpin* would be the better flower. *Olivia*, another of Mr. Crosfield's flowers, was a very beautiful *Leedsii*, with pure white petals, very broad. The short trumpet of palest yellow, much crinkled or frilled at the edge, has a suspicion of green in it. Other flowers I have noticed at the Royal Horticultural Society's and other shows are: *Adela*, a *Barri* with pure white, overlapping, slightly recurving petals, 3¼-inch spread, with a very pretty pale yellow crinkled eye with a green centre. *Black Chief*, an all-red eyed *Poet* (Engleheart) with an extraordinarily dark edge that looks almost black, which I saw subsequently on Mr. Bourne's stand. *Boadicea*, enormous white trumpet, slightly hooded. *Clipper*, large starry-petalled flower, clear self orange red cup, 1-inch spread and three-quarters of an inch deep, serrated edge (Wilson). *Deepdale*, a giant *Leedsii*, which was given an award of merit at *Edgbaston* (Milner). *Dovedale*, large, even-petalled flower, dark yellow cup, thin red edge (Milner). *Felix*, a seedling from *Brodie* (*Jeannie Woodhouse* × *King Alfred*), dark yellow trumpet, very reflexed rim, yellow hooded perianth. *Finespun* (Cartwright and Goodwin), large long-cupped. *King Cup*, said to be the result of the cross *King Alfred* and *Mme. de Graaff*. *Flame* (which, by the by, is a theft of a name registered by me!), a flat orange scarlet-eyed satiny white flower raised by Mr. Engleheart, and now in Messrs. Cartwright and Goodwin's hands, I believe. *Idris*, a large *Leedsii* with small cup of pleasing yellow (Watts). *Imperialist*, large orange flat eye, pure white perianth, 3¼-inch spread, broad petals, 1½ inches, rather blunt-ended. *Henry James*, a flat golden yellow-eyed flower, with fine large petals white and overlapping. *King George IV.*, a narrow-petalled *Miss Willmott*. *Killecrankie* (Crosfield), a large yellow trumpet *Leedsii*. *La Lure*, an enormous-mouthed short trumpet 2 inches across by 1½ inches deep, of pleasing light yellow colour; perianth white, of great substance; broad petals 1¾ inches by 1¼ inches, small petals 1 inch broad. *Little Joan*, already described by Mr. Jacob, a lovely *Ivory* and *Pink shell-like* flower. *Marsh*

Maiden, a very good pure white trumpet, flower-perianth broad and overlapping, but not quite smooth; trumpet shortish, and very much turned back and frilled at edge. *Potent*, a magnificent giant *Leedsii*. *Roseate Dawn* (shown as *Early Dawn*), a very open-mouthed *Leedsii*; trumpet much serrated and reflexed, and coloured distinctly a pink shade at mouth; perianth with 1½-inch petals, 1½ inches broad. *Vestal Virgin*, a massive white trumpet flower; perianth 1½ inches; petal, 2 inches long; trumpet palest lemon, 1½ inches long, 1½ inches wide; lip turned well back, slightly drooping; 18-inch stem. May I add that *Pink Beauty* and *Chameleon* have flowered very well with me this year, the former making a most delicate bit of colour in the flower-beds.—C. LEMESLE ADAMS.

Fruit Blossom and Frost.—The note under the above heading on page 225 of last week's issue compels attention to the immense importance of affording some effective protection to the trees during the flowering period. The fruit-growing industry has grown so enormously of late years that it may now justly be called a national industry of no mean importance, and the loss sustained by those engaged in the business is a heavy one, with, unfortunately, no chance of making it good until another year. If such more or less preventable damage was inflicted periodically on the property of other traders or professionals, there would have been such a hue and cry against it that a remedy by protection or insurance, or in some other effective way, would have been forthcoming long ago. But the sufferers being simply poor horticulturists—a body without soul, unity or purpose, as far as its national interests and existence are concerned—the tragedy goes on, and apparently is likely to go on for ever. Cannot something be done to, at any rate, mitigate the severity of the losses? Could not a Government Commission be appointed to take evidence and find out, if possible, whether any effective and practicable scheme entailing but moderate cost in its application could be found; and if found, its provisions made compulsory by law, the same as is the case now in respect to the *Gooseberry mildew*? Something effective in this direction has already been done, especially in the county of *Worcester*, where much land is now given over to fruit culture. One gentleman, Mr. Bomford of *Leigh Farm*, near *Worcester*, a large grower, with whom I had a conversation on the subject last winter, has great faith in the efficacy of a strong potter of warm smoke emitted from lamps secured to stakes and fixed at certain distances apart throughout his orchard. He has had the system in operation for many years, and he assured me that in consequence he had had only two failures of crops in thirteen years, and that some of his crops in some seasons more than bought the freehold of the ground on which they were growing. The orchard in question consisted of Apples, Plums, *Gooseberries* and *Black Currants*. The lamps are filled with a liquid which, when ignited, gives off a strong potter of warm, dense smoke, which warms the air and thus keeps frost at defiance. An alarm is provided in the orchard by fixing a thermometer in an exposed part with an electric wire and bell attached. The bell rings in Mr. Bomford's room as soon as the mercury in the thermometer falls to freezing-point. The lamps are then lit, no matter what time of the night it may be, if deemed necessary. The cost is said to be comparatively small.—OWEN THOMAS.

Grape Hyacinths as Cut Flowers.—It is, of course, a matter of taste, but I can hardly imagine short-stemmed flowers like the Muscari looking their best in vases a foot high as advised on page 189, April 20 issue. When having occasion to use them, I find they are much more effective when arranged in shallow bowls as a groundwork for the smaller-flowered Narcissi. A very charming combination is Narcissus Leedsii Mrs. Langtry or Duchess of Brabant and Muscari Heavenly Blue. In the borders, planted alternately in bold clumps with the yellow or sulphur Daffodils, they are equally effective and make a pleasant contrast of colour.—H. S. W.

Bedding Tulips.—Like your correspondent "A. D., Kingston-on-Thames," who writes on page 202, issue April 27, I have never seen Tulips better in colour, evenness of flowers, and in other ways more satisfactory than they have been during the present spring. When the plants first showed their flower-stems, they looked somewhat weakly, but directly the warmer weather came they commenced to strengthen rapidly. In the Bournemouth public gardens there are many large beds filled with Tulips mainly, and they have been splendid, large blooms borne on long but stout stems. The flowers are very even in size, and there are no gaps. Undoubtedly the bulbs were well ripened last summer, and in proof of this, when the bulbs came to hand in the autumn, many of them peeled very much; but, of course, the loss of the outer skin in no way interfered with the flowering of the bulbs.—G. G.

Exhibition versus Private Garden Flowers.—"An Amateur," page 214, issue May 4, seems to have a grievance against exhibition flowers, and lays extra stress upon professional florists and their advertisements. Having had a very wide experience of exhibitions in various parts of the country, I do not hesitate to say that the amateur cultivators are now in the front rank as exhibitors; furthermore, that shows are far more numerous now than they were a generation ago, and that it is to a very great extent owing to the produce staged at the exhibitions that emulation has been widely roused among amateurs, and the beneficial effect in the gardens throughout the country is now only too apparent. I need only refer to the improvement in Roses, Carnations, Begonias, and alpine plants. People flock to the shows in order to learn, to see the advance made in garden produce. Witness the Sweet Peas and the herbaceous flowers now staged at exhibitions. Do they not suggest cut-and-come-again in their case? I think so. I do not wish to write a long note on this subject, but would like to say that the public are the best judges, after all, and flowers are universally grown according to their approval or disapproval, and the professional florists are the first to find out this.—B.

FORTHCOMING EVENTS.

May 21.—Preston (Somerset) Gardeners' Society's Meeting. Croydon Horticultural Mutual Improvement Society's Meeting.

May 22.—Royal International Horticultural Exhibition. Opening ceremony by His Majesty the King at 12 noon in the Chelsea Hospital Gardens. Exhibition open to the public on every day until May 30 inclusive. Bath and West and Southern Counties Show at Bath (five days). Royal Botanic Society's Meeting.

May 24.—Linnean Society's Meeting and Anniversary. Hertford Horticultural Society's Meeting.

May 25.—Wakefield Paxton Meeting.

THE ROSE GARDEN.

THE MUSK ROSES.

THE Immortal Bard, when he alluded to "sweet Musk Roses" in "A Midsummer Night's Dream," had probably some other Rose in mind than *Rosa moschata*, or *Brunonii* as it is sometimes called, for this species has very little of the fragrance of Musk about it; in fact, Mr. Sawyer, in his interesting discourse on the odour of the Rose in "Rhodologia," says that *R. Brunonii* develops a fine odour of Pinks.

In some of the varieties that are descendants of *R. moschata* there is a distinct Musk-like fragrance very perceptible after a shower.

The species is found from Southern Europe to India, which may account for its somewhat tender nature; but there are few gardens in England where it could not be grown, although it seems to revel in gardens near the coast. I have seen some magnificent examples of *R. moschata* in the late Lord Battersea's lovely gardens near Cromer.

Like many rambling Roses, the Musk Rose likes a position where it can ramble away unmolested by pruning-shears, and it makes a fine show drooping from a lofty balcony or clambering over an old tree. There are some interesting Hybrid Musk Roses now in cultivation, and perhaps it may be well to name a few. I quite expect this species will be used by hybridisers more frequently than hitherto. I see Messrs. Paul and Son of Cheshunt, ever alive to the creation of good garden Roses, are crossing the Polyanthas and Musk Roses together. A novelty they announce for distribution in June is named

Queen of the Musks, and it is described as a new departure in the Dwarf Polyantha Roses, the novelty having large bunches of creamy white flowers with pink centres, the buds being rosy pink. Another fine Rose from the same raisers is

Snowstorm, producing an almost continuous display of white, semi-double blooms. In growth it resembles *Alister Stella Gray*, so that it may be the forerunner of a race of perpetual-flowering semi-climbers. Already we have promise of some good things among these semi-climbers, and our gardens will welcome every one, so that the pillars at least, if not the arches, will be gay with bloom at a season of the year when we value them so much.

The Garland is undoubtedly a Hybrid Musk. It makes a perfect fountain of bloom if planted as a free bush where it can have abundance of space. A position of about five yards square would be none too much for a single plant, and there are many gardens where this could be given on the lawn or in an open space in a wood. To see such Roses grow to perfection, large holes should be taken out fully 3 feet deep and wide and filled with good soil and manure. What a delight it would be to come upon such specimens even in the woods and copses that adjoin many gardens! One plant will carry thousands of blooms, which expand about mid-July and exhale quite a Musk-like fragrance. The blooms are buff-coloured.

Mme. d'Arblay, too, is finding favour more every year, its lovely semi-double, snow-white blooms being produced in great profusion, normally about the end of June; but here, on May 1, it was already in bud this year, which shows how remarkably early some things are. *Mme. d'Arblay* will make huge, thick growths with very formidable prickles. It is best seen, I think, as a pillar Rose.

Rosa Pissardii is another hybrid that possesses the perpetual-flowering character, and which should be serviceable to the hybridist. There are two forms, one white and the other pink.

R. moschata alba, although so named, cannot be related to the true Musk Roses. I should say it belongs more nearly to *R. gallica*.

Rivers' Musk is a pretty autumn-flowering hybrid with buff pink blooms, double, and of nice form.

Eliza Werry has large trusses of small nankeen-coloured blooms, produced about the third week in July.

Fringed Musk has cup-shaped flowers of buff white colour, and

Princesse de Nassau bears yellowish straw-coloured cup-shaped flowers, very sweet and double. These last four would be excellent as pillar Roses to flower about the third week in July.

One could readily believe that the old *Noisette* Roses have descended from *R. moschata* crossed with some other species, for they possess that aromatic fragrance so peculiar to the Musk Roses, and, as I said before, there is scope for the hybridist to use these to great advantage. P.

OUR SUMMER ROSES.

WHILE looking at the display of Tea and Hybrid Tea Roses last autumn, the thought came to me how very few years ago it was since the term "summer" Roses was applied to those that only bloomed once in the season; also, how very few we had that were worthy of the name of summer bloomers. Now we do not have to grow so many varieties in order to keep up a succession of flowers, for the true summer bloomers are the beautiful hybrids that do not leave us from June until that first severe frost arrives which cuts down all floral beauty. In constant succession there are blooms of *Mme. Ravary*, *Anna Olivier*, *Peace*, *G. Nabonnand*, *General Macarthur*, *Le Progrès*, *Mme. Antoine Mari*, *Corallina*, *Melanie Soupert*, *Viscountess Folkestone*, *Richmond* and *Grüss an Teplitz*, to name the first dozen occurring to me as I write. There are a hundred more varieties among which it would be hard to say which are the most generally useful. About twenty years ago the National Rose Society and many growers were strongly against forming this new class. But it soon came to pass that only a very few could refrain from making some distinction as the several beautiful introductions followed year by year. It is invidious to choose one class or section alone, for all are beautiful and well suited for some purpose; the sole fault lies in our not studying the best purpose more closely. In all classes or sections there are varieties now which are totally different in habit to the general character, and consequently the purposes they are best adapted for differ considerably.

I am certain a bed of *Mme. Ravary*, also one of *Mme. Pol Varin-Bernier* that I saw last autumn, could not have been improved upon for massing. And yet how often we find ill-placed mixed beds, from which the effect is never so pleasing. To plant a variety which throws up an occasional growth of extra strength by the side of one that is invariably compact makes the whole effect bad. I did not think of giving any descriptions of varieties here nor names. Any good catalogue will afford them far better than can be done in a short article of this description; but I would remind any prospective purchasers that they may depend upon the sorts a recognised grower describes as being most reliable, and we have, fortunately, many such now. A. P.

THE GREENHOUSE.

DAPHNE ODORA ALBA.

THE beautiful *Daphne odora* and its varieties *rubra* and *alba* are largely cultivated in gardens, being highly prized for their deliciously fragrant flowers, which are produced during the first three months of the year, a

season when such flowers as those of the *Daphne* are particularly valuable. Although they will succeed and flower profusely out of doors in the warmer parts of the country, they are, strictly speaking, cool greenhouse plants.

As these *Daphnes* are somewhat slow-growing, they require careful treatment, and on no account should they be overpotted. Watering must also be carefully attended to, especially in winter. During the growing season the plants delight in a warm, moist atmosphere. After growth is completed for the season, place them in a drier and more airy situation; this will enable the wood to become thoroughly ripened, which is necessary for the production of flowers.

The plants will succeed best in a rich, open compost consisting of two parts peat to one part of fibrous loam, with a good proportion of sand added. Good drainage is also an essential point. Propagation may be effected either by cuttings or grafting, using *D. Laureola* as a stock. Plants, however, on their own roots are to be preferred, these being generally longer-lived than grafted plants. Cuttings of the half-ripened wood taken off in August root readily if inserted in sandy soil and placed in a propagating-case with a temperature of 55°.

Although the variety *alba* illustrated on this page is not so often met with as *D. rubra*, it is quite as beautiful, and is to be especially recommended where white flowers are in demand. *D. odora* is a native of China, and was introduced into this country in 1771. It is more generally met with in gardens under the name of *D. indica*.

A SWEET-SCENTED GREENHOUSE PLANT.

ALL lovers of sweet-scented flowers should grow *Boronia megastigma*, a charming denizen of New South Wales, whose small, cup-shaped bells, maroon on the outside and yellow within, hang poised from the whole length of the slender, graceful shoots. It is the possessor of fragrance of a high and rare order; high because of the delicacy of its perfume, which is refined and almost indescribable, about which there is nothing redundant or cloying; and rare because of its extraordinary carrying power. A single plant will waft its aromatic message through a whole house, and a *Magnolia's* sumptuous perfume can scarcely do

more. When 5 yards distant from the open door of a greenhouse in which a solitary plant of this *Boronia* is in flower, one becomes conscious of its odour, yet the scent, though perceptible at long distances, is never powerful.

Flowering plants of this *Boronia* may at the present day be purchased at a low price. If these—after their blossoms, which are very lasting, have faded—are cut hard back and, after breaking again, are repotted, care being taken that the roots

FLOWERING SPRAY OF *DAPHNE ODORA ALBA*, A FRAGRANT PLANT FOR THE GREENHOUSE.

are not disturbed, and given a shift into pots one size larger, using peat and a little sand, and keeping them in a warmer position for a week or two, they will soon throw out shoots, which, if an increase is desired, may be taken off when about two inches long, inserted in well-drained pans in equal parts of peat and sand, and placed in a warm house in a propagating frame until rooted, shading from sunlight when necessary. When well rooted, they may be potted off singly, the tops being pinched when they show signs of renewed growth.

The old plants, when their growth is completed, should be placed in the open for a month or six weeks, in order to solidify the wood. In sheltered gardens in Devon and Cornwall, *B. megastigma* is often grown in the open, and may be seen in the late spring bearing a good crop of its deliciously-scented flowers.

WYNDHAM FITZHERBERT.

THE FLOWER GARDEN.

SEASONABLE NOTES ON CARNATIONS.

The Buds.—A considerable diversity of opinion exists as to the extent to which Carnations and Picotees growing in borders ought to be disbudded. There are some cultivators who do not hesitate to decide in favour of the removal of all except the crown or central bud; others are equally as firmly convinced that three buds is the correct number to retain; while a third group avers that not one bud should be removed, because so doing constitutes an unnatural method of culture. Personally, I much prefer to rest among the second section, as I think that a group of three perfectly-formed flowers is the acme of beauty. Something must be said in favour of the most severe form of disbudding, and which is only had recourse to, as a rule, by those who hold exhibiting the principal object of culture. My sole reason for not advocating it lies in the fact that it has a tendency to encourage coarse blooms. A plant in splendid health, with its roots working in excellent soil, builds up immense energy, and it is seldom conducive to refinement to restrict the flowers to one on each stem. For size the individual bloom has the lead, and if coarseness does not accompany the repression, any objection to the practice falls to the ground. I have no sympathy with those who do no disbudding at all, as I think that the plant loses materially in charm. The suggestion that the system is unnatural is puerile. Scarcely any plants are grown quite naturally, and it is certainly intended that we shall vary from the normal if such variation tends to our substantial advantage.

Supporting Flower-Stems.—

It is essential that this shall have the most careful attention. There are several ways of doing it, of which the worst, and

it is to be feared the commonest, is to put one stick in the middle and pass a piece of bast or string round the stake and shoots. This brings them together in an ugly mass, and, apart from destroying the attractiveness of the habit of the plant, puts beyond the realms of possibility the development of any perfect flowers. Another method is to use galvanised twisted supports, and against these little can be said, provided that the grower is incessantly on the watch to see that the stem does not kink in the twists. If this occurs, the beauty of the flowers is minimised if not destroyed. The third system is to place a slender stick for each stem, attaching it with a thin strand of bast. More time is involved when the work is done in this manner, but there is no doubt that it is extremely satisfactory.

Green Fly and Thrips.—The grower of Carnations out of doors cannot claim that many enemies attack his plants when the conditions of soil and situation are favourable; but it is all too seldom that one wholly escapes from a visitation of green fly, and it is too common for thrips to gain a hold in many gardens. Either of these pests, if allowed to become comfortably and strongly established, will do vast injury and ruin all prospects of the finest results. Therefore cultivators must be constantly on the watch for them with a view to the destruction of the first one that comes along. The persistent searching may be a little monotonous, but it brings a wonderful pleasure when an enemy is seen to kill it without delay. The error of waiting until the pests are numerous is fatal, and entails endless labour and worry to ensure complete riddance. Syringing with pure water in the early hours of fine mornings is an excellent step towards prevention and suppression, but it must obviously be commenced in good time, or it will fail.

Hoeing.—Fresh air is as necessary to the maintenance of perfect health in the roots of the plants as it is to their top growth, and its admission ought to be encouraged at all seasons of the year. It is not a serious matter frequently to prick over the surface with a hand-fork, or to run the Dutch hoe between the rows if it can be managed without risk of injury to the roots or the stems, and air will then find its way in. The rains which fall will penetrate instead of running off, and air will assuredly follow the water. Beyond this, and in its way of equal importance, the dustiness of the top prevents the waste of plant food by the ever-proceeding capillary attraction. F. R.

A LITTLE-KNOWN ITALIAN SQUILL.

(*SCILLA ITALICA ALBA*.)

THE Italian Squill is a pretty *Scilla* which is not much known at the present time, and has been but seldom offered in catalogues until lately. A fresh supply has apparently been procured from Asia Minor, and bulbs have lately been catalogued and are sold in the shape of mixed varieties. The writer has cultivated the blue Italian Squill, originally introduced, I believe, from Italy (hence the name of *S. italica*), for a good number of years, and Maund figures in the "Botanic Garden" this and a white and a rose variety. The rose one does not seem to be procurable at present, but, through the kindness of a lady well known in the gardening world, I was favoured with a few bulbs of the white one, which is here figured from a photograph taken in April, 1912. It is a charming little plant, only about six inches to ten inches high, with conical heads of pure white flowers and neat leaves. This white variety increases more slowly than the blue one, and is as yet very scarce in

gardens. I cultivate it in light, well-drained soil, and with me it appears to have a preference for a semi-shady spot. S. ARNOTT.

DAFFODIL NOTES.

Exhibition versus Private Garden Flowers.—I agree with "Amateur," page 214, issue May 4, more nearly than she thinks I do. As may be gathered from my notes in the issue of May 4, I fully recognise that a Daffodil for the exhibition and a Daffodil for the garden are more often than not two distinct things. The difficulty is how to let the "private public" know which are the best ones for their gardens. My suggestion is northern and southern trials, *à la* Sweet Peas; but without a National Daffodil Society I do not see how it can be satisfactorily accomplished. Like many other things in modern life about which we are doubtful, the "show" Daffodil has come to stay; at any rate, for some years yet. I very

they would be few. So with exhibitions—no "florist" flowers, no public. A second point of view is that Daffodil shows and the aiming at "show" blooms tend to the general improvement of the race, just as agricultural shows and racing promote the breeding of horses of better "stamp." Take some of the Daffodil cast-ups of the advancing tide. Take as typical examples White Lady, Lady Margaret Boscawen, Blackwell and Cornelia. As the refrain of a pantomime song of early days, which is continually jingling in my ear, says:

"What can you wish for more, my boys?
What can you wish for more?"

Hence I would ask "Amateur" and our friends the great "private public" to tolerate shows and what follows in their wake; but to remember when they attend them to order warily, and when in doubt to consult someone who knows the way of the creature.

Garden Varieties.—A great friend of mine, who is biting hard and whom I soon hope to hook as a Daffodil exhibitor, told me the other day that my notes this year had not been of such general interest as usual, because I had rather neglected the better average flowers. I presume he meant he was not prepared to buy such an admirable set as those Messrs. Pearson and Sons advertised in last week's GARDEN. I must own I have erred in this respect. I should have remembered that as things are, the "private public" must largely rely on note-writers like myself. *Peccavi*. And now to make amends if I can—to the garden plant-seekers first; to the would-be showman later on. Here are a few really good new things for the garden: Stromboli (Lilley of Guernsey), a grand palish yellow Ajax, whose special points are size, earliness and tall growth. Golden Spider (Polman Mooy), a slightly paler and later but better formed Golden Spur. I find it very free and a good doer. Solfatare, a most lasting yellow incomparabilis of medium height and pale pleasing colouring. Hall Caine (van Waveren), a tip-top garden variety of immense size and height, a little in the way of the old Frank Miles. It is some years since I first saw it at Hillegom, and forthwith transferred some of it to my own garden, where I am more and more impressed with it every year. Orient, the best and most lasting of *all* the Poetaz for out of

THE WHITE ITALIAN SQUILL, *SCILLA ITALICA ALBA*.

much doubt if even "Amateur" herself would not soon get tired of going to exhibitions where only good garden varieties were to be seen. I think from reading between the lines she recognises this. Theoretically, there should be, I suppose, some "sport" in shooting, and it should not be a sort of who-does-best at a flying target. Practically, it is found by those who give shooting-parties and want guests; it must be so, otherwise

doors. It has good foliage and bears almost always three large, undulating flowers on a stem which rises well above the leaves. In the distance it appears an ivory white, but on closer inspection one sees the pale yellow cup slightly margined with red. Thora (W. T. Ware), a giant Leedsü, tall and very free. With age the large cup assumes a more or less apricot tone, especially under glass. I could write an interesting history of the plant

and how I gradually found out its various qualities for pots and for exhibition on account of its wonderful colouring that comes with age, and for the garden because of its habit, freedom of flowering and size. Constellation, which reminds me of Cynosure, is a decided acquisition. It is very free and a splendid laster. Spinnaker (Hogg and Robertson) is a pointed Lady Margaret Boscawen and about equally effective. I mention it as it is not so expensive. Cassandra, Ben Jonson and Spenser are an excellent selection of the newer Poets, and they are chosen because they have not so much red to burn and because they do not go wingy. Until Florence Pearson and van Tubergen's Zwanzenberg become "practical purchases," I do not see anything that ousts Mme. de Graaff from its position as premier white or palest bicolor trumpet. Of the deeper bicolors, Duke of Bedford and Coronet both have their special claims to notice. The former has size and importance; the latter has earliness and distinctness in trumpet and colour. So I might go on with several more, and long as my list might grow, no red cups would be found in it. The omission is intentional. I would rather they were bought off the purchaser's own bat. With very few exceptions they all fade and "burn" unless they are in some way shaded. With regard to Seagull, White Lady, Lucifer, Blackwell and Torch, they are not mentioned, as I expect all garden planters of Daffodils know them so well.

THE BEST DAHLIAS AND THEIR CULTIVATION.

THE Dahlia is an ideal late summer and autumn flower, and is admirably adapted for town gardens where many other flowers will not thrive owing to the smoky atmosphere. I have seen perfect specimens of the Cactus type grown in Clerkenwell and Stoke Newington. In the former case they were grown in tubs on the flat roof of a house, and the receptacles used were the ordinary margarine or butter tubs, which were first thoroughly burnt out with lighted paper, and then holes about the size of a sixpence burned through the bottom for drainage.

The planting of Dahlias should be done now. The ground ought to be well dug over to a depth

of about two feet and thoroughly broken up, and a liberal quantity of old, well-rotted manure mixed with the soil. The plants, if grown in beds, should be quite 3 feet apart, and a strong stake should be placed in the soil at the time of planting about four inches away from the plant. The stake ought to be at least 5 feet in length. Novices often wonder why such long, unsightly stakes are put in at the time of planting; but to the experienced gardener it is obvious that to insert such a stake at a later period, when the plant has grown 2 feet to 3 feet in height, would mean irreparable damage to the tubers or roots. The plants should be well watered after they have been put in, and loosely but securely tied to the stake with raffia or bast. As the plant grows, the tying process should be continued, fresh raffia being added as needed.

should be given not less than a gallon at each time. Dahlias are very gross feeders, and almost any animal manure is suitable. It may either be dissolved in a tank loosely or placed in a sack and allowed to escape gradually. The feeding with manure-water should always follow after the usual watering. Each plant should be given about one gallon. It is never necessary to feed as much in rainy as in dry weather.

As the blooms begin to open, a sharp look-out must be kept for earwigs and caterpillars. The best plan is to place a 2½-inch pot partly filled with greasy paper on the top of each stake. The pots should be examined every morning and the earwigs and other insects found in them destroyed. The best time to catch these pests is after dusk. The blooms should be carefully looked over with the aid of a lantern. The Pompon varieties do

not require thinning out, disbudding or feeding, and they do not grow so tall as the other varieties.

Dahlias should never be planted in a shady position or allowed to be crowded by other plants or shrubs.

The following is a first-rate dozen of both the Cactus and show sections: Cactus—Ajax, orange buff; Advance, scarlet terracotta; Débutante, peach pink, creamy centre; Dorothy, silvery pink; Dreadnought, dark crimson maroon; Glory of Wilts, pure yellow; H. H. Thomas, scarlet crimson; Mrs. Macmillan, pink, with white centre; Nellie Riding, crimson,

A BEAUTIFUL ROCK GARDEN PLANT, ANDROSACE CHUMBYI. (See page 243.)

JOSEPH JACOB.

Some varieties grow much taller than others, and it is always better to consult a catalogue that explains the height of each variety before putting them in position. When they reach about two feet in height, two other stakes—the same length as the first—should be put in about one foot from the plant, the three forming a triangle.

Thinning and disbudding in the case of the Cactus, decorative and show varieties will cause some anxiety to the beginner. If quantity in preference to quality of blooms is required, it is usual to leave about six main stems; but if exhibition blooms are wanted, the main stems should be reduced to three or four. Shoots multiply very quickly and need taking out from their base. No plant should be allowed to become in the least degree crowded.

As the summer advances they will require a liberal amount of watering—on an average twice a week if the weather is hot and dry. Each plant

with white tips; Rev. T. W. Jamieson, coral pink, with creamy centre; Snowstorm, pure white; and William Marshall, bronzy yellow. Show—A. M. Burnie, orange, with yellow edge; Blush Gem, white, tipped with mauve; Countess, bluish white, shaded rosy purple; Goldfinder, yellow, tipped with red; Harry Keith, rosy purple; J. T. West, yellow, tipped purple; Mrs. Gladstone, soft blush; Mrs. Langtry, cream, edged with crimson; Nugget, orange, tipped scarlet; Sulphurea, sulphur yellow; Tom Jones, creamy yellow, edged with rose; and William Rawlings, crimson purple.

WILLIAM BIGGS.

NEW TULIP VELVET KING.

THIS handsome variety gained the distinction of an award of merit when shown on the last day of April before the Royal Horticultural Society. It is a Darwin variety, and the large, globose flowers are of a dark glossy purple, suffused with a

bronzy hue. The flowers are borne on long, stout stems, and judging by its robust habit, the new-comer has the making of a useful garden variety. It was shown by Messrs. Barr and Sons, Covent Garden.

THE ROCK AND WATER GARDEN.

ANDROSACE CHUMBYI.

ACCORDING to the Kew Guide, this *Androsace*, or Rock Jasmine, is a hybrid between *A. sarmentosa* and *A. villosa*, though as I know it the flowers are a deeper colour than is usual in *A. sarmentosa*, while the foliage, though similar in shape, is smaller and neater. There seems to be some uncertainty among many gardeners with regard to the naming of these two plants, *A. sarmentosa* and *A. Chumbyi*. I notice in Meredith's "Rock Gardens" he speaks of *A. Chumbyi* as being a variety of *A. sarmentosa*, and then goes on to say that it is a stronger grower, deeper in colour, and the flowers are borne on shorter stems than in the case of *A. sarmentosa*.

As far as the last two characters are concerned, they agree with my experience; but the first point, viz., stronger growth, is with me the distinctive feature of *A. sarmentosa*, the summer rosettes of which usually measure $2\frac{1}{2}$ inches to 3 inches across, while the average diameter of my *Chumbyi* rosettes is 1 inch. However this may be, the plants I have under the name of *A. Chumbyi* (and I have every reason to believe them to be the correct thing) are most fascinating little things.

As in so many of the *Androsaces*, the leaves are arranged in rosettes and are very hairy, giving the plant a somewhat silvery appearance, and about May short stalks push up from the mature rosettes some 1 inch to $1\frac{1}{2}$ inches high, each bearing a truss of Primula-like flowers, pink in colour, the eye of which is usually yellow, though I notice in some of my flowers it is of a full dark red.

At this same time the plant produces somewhat Strawberry-like runners, and at the end of each is a new plant. Frequently a single rosette will give off five to eight of these. From the junction of the rosette with this cord or runner new roots are formed, and in this way the plant spreads into a larger patch, and, what seems to be most important of all, permits it to extend on to fresh ground.

With me the plants thrive in very gritty soil, those shown in the illustration on page 242, being in a compost which is about intermediate between the ordinary gritty alpine garden soil and the moraine, and consisting roughly of one

part of loam, leaf-mould, old sifted mortar and sand to each four parts of broken brick which has been passed through a half-inch sieve.

In this gritty medium, kept *amply* moist from early April till July, my little colony is extending very happily, the chief enemy being the damp, foggy days of autumn and winter, during which dirt and other by-products of the city's vapours descend upon the silky rosettes, and would in a short time poison them if precautions in the shape of a sheet of glass, supported some little distance above the clump, were not taken to intercept them. Such a glass sheet effectually achieves this result, and yet allows an ample current of air to

DEUTZIA LONGIFOLIA, A BEAUTIFUL NEW CHINESE SPECIES THAT IS HARDY IN THIS COUNTRY. (See page 244.)

pass over the downy foliage, so modifying the liability of the plants mildewing.

Woodford, Essex. REGINALD A. MALBY.

SAXIFRAGA BATHONIENSIS.

THIS is one of many varieties of *Saxifraga decipiens*, but it is probably the finest of its kind yet raised. It is a rapid grower, and as an edging plant for a garden path it is likely to become as popular as Thrift or Sea Pink. It is of dwarf, compact habit, and in the springtime its glory is enhanced by a profusion of scarlet-crimson flowers. The individual flowers are much larger than those of similar varieties.

TREES AND SHRUBS.

SOME GOOD GARDEN CLEMATISES.

THE coloured illustration of Clematis Lady Northcliffe which forms the front cover of this week's issue directs attention to an important and popular group of hardy climbing plants, for when well grown there are few subjects which better repay the efforts of the cultivator than the various kinds of garden Clematis. Unfortunately, they are sometimes rather difficult to manage, for after making

satisfactory growth for some months, or perhaps for a year or two, they collapse and die without any warning. Numerous theories have been brought forward to account for this peculiarity, the most practical one being that they suffer from overheating of the stems near the ground-line. There appears to be good reason for this idea, for plants which have the lower parts of the stems exposed to full sun suffer worse than those which have their roots shaded. The upper parts, however, enjoy sun; therefore it does not do to select a sunless position. Good loamy soil containing lime provides the best rooting medium, while a surface-dressing of well-rotted manure may be given occasionally with advantage. Two methods of propagation are adopted. Sometimes sections of the stems of good varieties are grafted upon roots of the common *C. Vitalba* and at other times cuttings are rooted during summer.

Numerous positions suitable for Clematises will suggest themselves to the owner of a garden. Planted against a pergola they give an excellent account of themselves; for covering summer-houses or trellises they are equally desirable; while for growing among Ivy on the walls of dwelling-houses they have much to commend them. A use to which they might be more often put, however, is to plant them about the bases of evergreen bushes, stunted trees or Ivy-covered trees, and allow them to ramble at will among the branches. Under such conditions they frequently make charming pictures. In some gar-

dens they are popular for growing in pots, their branches being trained over large wire balloons. Such plants have frequently excited the admiration of visitors at the various horticultural exhibitions held in the Temple Gardens. Pot plants of a less ambitious type find their way into our flower markets in spring. These are usually year old plants grown in 5-inch or 6-inch pots, bearing from six to twelve flowers each. They are very useful for greenhouse decoration, and may be planted out afterwards.

The garden Clematises are divided into several well-marked groups, which succeed each other in flowering. They commence in May and June

with the patens and florida sections; then come the lanuginosa varieties, followed by the various kinds which compose the coccinea, Viticella and Jackmanii groups.

C. patens is a native of China and Japan, whence it was introduced about 1836. Growing 10 feet or 12 feet high, it bears three-parted leaves and large mauve-coloured flowers, which have the segments rather widely separated. The various varieties differ in colour to some considerable extent. A good selection is as follows: Edith Jackman, white, flushed mauve; Fair Rosamond, white, flushed with rose; Lady Lonsborough, silver, with reddish bars; Mlle. Torriana, rose, flushed purple; Mrs. George Jackman, white, with brown stamens; and Sir Garnet Wolseley, blue, with reddish purple bar.

C. florida, a Japanese species, has been known in English gardens for nearly a century and a-half. This and its varieties may be distinguished from the foregoing by the more formal-shaped flowers, with their segments touching or overlapping each other. There are both single and double flowered varieties, of which a selection is appended: Belle of Woking, silver grey, double; Countess of Lovelace, pale blue, double; Duchess of Edinburgh, white, double; and Proteus, purple. Neither of these two groups of varieties requires much pruning, any little which may be required being left until after the flowers are over.

C. lanuginosa is a Chinese plant of vigorous habit bearing very large flowers during July and August. Good ones are Blue Gem, violet blue; Beauty of Worcester, bluish violet; Fairy Queen, flesh, with pink bars; Gloire de St. Julien, lavender, very large; Henryi, creamy white; Lady Caroline Neville, lavender, with purple bands; La France, violet purple; Lord Neville, bluish; Lady Northcliffe, blue; Marcel Moser, lavender, with carmine violet bands; and Robert Hanbury, violet, tinged bluish.

C. Viticella.—This is a very floriferous species, native of Europe. The deep purple flowers are smaller than those of other kinds. Ascotensis has violet flowers; La Nancienne, double violet; J. alba, white; rubra and grandiflora, red.

C. Jackmanii originated as a hybrid between *C. lanuginosa* and *C. Viticella*. It is very floriferous, blooms during autumn and bears purple flowers. There are, however, forms with red and white blossoms. The following are good ones: Gipsy Queen, violet purple; Jackmanii superba, deep purple; J. alba, white; J. rubra, red; Mme. Baron Veillard, lilac rose; Mme. Edouard André, red; Alexandra, violet; magnifica, reddish purple; Othello, purple; Snow White, white; and Ville de Lyon, red.

C. coccinea.—From this herbaceous scarlet-flowered species crossed with garden varieties

several curious and showy hybrids have been raised. Countess of Onslow, violet purple; Duchess of Albany, pink; Duchess of York, pink; Grace Darling, bluish pink; and Sir Trevor Lawrence, crimson, are all good. D.

A NEW CHINESE SHRUB.

(*DEUTZIA LONGIFOLIA*.)

As stated in our issue for last week, page 235, this delightful novelty must presently be demanded in its thousands. The great charm of the species is the pink colouring of the flowers, which appear in axillary clusters on every twig and branch, large or small, a feature that is made quite clear

A BEAUTIFUL NEW DARWIN TULIP, VELVET KING. (See page 242.)

in the illustration on page 243. It was introduced from China by that assiduous collector, Mr. E. H. Wilson, and as a free-flowering hardy shrub it is likely to become immensely popular.

THE KITCHEN GARDEN.

WINTER AND SPRING BORECOLES.

DURING the past few weeks in many parts of the country there has been a great scarcity of good Borecole, and under this heading may be classed the Scotch and Curled Kales, the Sprouting or Hybrid and the older forms of Cottagers' and

Asparagus Kales. For an early supply my note does not apply, as the seed should have been sown before this, but for a late supply I would advise May sowings; indeed, in the South I have sown early in June, and by so doing secured a dwarfier plant and a later supply, as with good culture the plants grow rapidly and give a good return. In the North earlier sowings are made, but in this respect so much depends upon soil and situation. I prefer to plant out the seedlings much smaller than is often done, thus getting a dwarfier plant than when left to become drawn in the seed-beds.

The Kales, as regards soil and situation, are by no means fastidious. They will grow well in any position, and well repay deep culture. As regards the varieties, which are now somewhat numerous, they are all fairly hardy. For instance, take the variegated Kale, nice in appearance with its highly ornamental leafage with so many varied colours, but of less value as a good late vegetable than the green type. The Arctic Kales are deep green in colour and beautifully curled, also of good quality, and they are not gross growers, being admirably adapted for gardens limited in size. The Drum-head Kales, a variety of somewhat recent introduction, are a most valuable addition to our hardy vegetables and delicious when cooked; indeed, in this respect they resemble the early spring Cabbage, have a solid Cabbage-like head, and are remarkably hardy. Another type less known are the Sprouting Kales or Hybrids. I should say even of these there are two distinct varieties—those that make an upright growth like a Brussels Sprout and have their stems studded with close, compact shoots, and others of a much looser build, with longer shoots, and somewhat earlier. The Hybrid Sprouts are splendid for late winter or spring supplies, but I find they are quite large enough for all purposes if sown in May. Sow very thinly to get a stronger plant, and plant out early on good land that has not previously borne a Brassica crop. Then there is the hardy Labrador Kale. This is superior and quite distinct from the older Buda. I think the new hybrids have quite eclipsed the older forms of Cottagers' Asparagus or Buda. They are more profitable, as they take less out of the soil and give a good return, the quality being superior; also, they are of great value for late supplies after the New Year and until May. A new Scotch Kale of great merit is the Victoria Kale; it is excellent for its keeping properties. The Dwarf Scotch, Extra Curled and Imperial Hearting are very fine late varieties.

A word as to culture, and this is very simple. Plant out early and give ample room, say, 2 feet between the rows at least for the hybrid forms and 12 inches between the plants in the row. For many years, to get a very late supply, I planted a portion on a north border. G. WYTHES.

GARDENING FOR BEGINNERS.

HOW TO BED OUT SUMMER-FLOWERING PLANTS.—II.

A LARGE, square-shaped bed may be effectively planted in a variety of ways. Of course, only one design is given in the accompanying plan, but I will mention others very briefly. The whole of the body of the bed may be filled with tuberous Begonias and edged with *Violas*, or it may contain one variety of a Zonal Pelargonium and have an edging of blue *Lobelia*. Heliotrope, with dot plants of *Fuchsias*, would look charming, the edging consisting of white *Lobelia* or white *Violas*. *Salvias*, with dot plants of *Lilliums* and blue *Violas*, *Ageratum* or blue *Lobelia*, would also look effective.

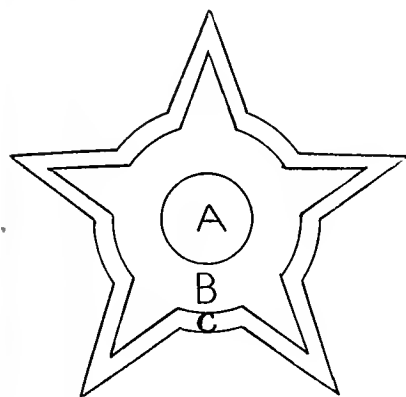

AN OBLONG BED TO BE FILLED WITH BEDDING PLANTS OR ANNUALS.

Fig. 1 as drawn. The centre, *A*, white *Marguerites*; the whole space surrounding *A*, yellow *Calceolarias*; *BB*, Zonal Pelargonium King of Denmark; *CC*, white or cream-coloured tuberous *Begonias*; *D*, Zonal Pelargonium Golden Harry Hieover.

The Same Bed Filled with Annuals.—The centre, *A*, annual *Chrysanthemums*; the whole space surrounding the centre, *A*, *Phlox Drummondii*; *BB*, *Zinnias*; *CC*, *Nasturtiums* King of Tom Thumbs (scarlet); *D*, *Mignonette* or *Portulaca grandiflora*; the latter would make a border of mixed colours.

Fig. 2: *A*, *Fuchsia* Lord Roberts; *B*, pink-flowered Zonal Pelargoniums; *C*, an edging of *Ageratum*.

The Same Bed Filled with Annuals.—*A*, *Calliopsis atrosanguinea*, scarlet flowers; *B*,

II

A STAR-SHAPED BED IS MUCH FAVOURED BY SUBURBAN GARDENERS.

Mignonette; *C*, an edging of *Nasturtium minus coccineum*, rich scarlet crimson.

Fig. 3: *A*, single-flowered *Petunias*, mixed; *B*, brown *Calceolarias*; *C*, an edging of *Geranium Little Dandy*. A dot plant of *Kochia* in the centre of *A* would look charming.

The Same Bed Filled with Annuals.—*A*, *Stocks*, mixed; *B*, *Asters*, mixed; *C*, an edging of *Mignonette*.

An Alternative Scheme.—*A*, *Godetia* Duchess of Albany, white; *B*, *Godetia* Lady Albemarle, crimson; *C*, an edging of *Nemophila insignis*, blue.

Distance Apart to Plant.—*Marguerites*, 18 inches to 22 inches; the size of the plants, so that when at their best they will not be overcrowded. Dot plants used, if 2 feet high, must not be closer than 3 feet 6 inches.

Soil and Manure.—Some lighter material must be put in for *Fuchsias* if the original soil be clayey. *Marguerites* and *Petunias* must not be planted in very rich soil. *Nasturtiums* require to be grown in poor ground; then the plants make moderate growth and flower well. Overcrowding is a common error in bedding, it being a mistake to grow six plants where one will suffice. G. G.

SUNFLOWERS AND DAHLIAS IN SHRUBBERIES.

ALTHOUGH it is advisable to plant temporary shrubs so as to give to the borders a furnished appearance from the beginning, it is unwise to overcrowd them. In due time, of course, the temporary shrubs must be removed, a few at a time, until only the permanent specimens are left, when these will need the whole of the space. In the meantime the new shrubberies may be made very attractive by planting *Dahlias* and *Sunflowers* in a judicious way, so as to fill up without in the least interfering with the shrubs themselves. In very dry soils it would not be

wise to plant the *Sunflowers*, as they would rob the shrubs of too much moisture. In no case must the *Dahlias* and *Sunflowers* be planted close together, but many feet apart, dotted about here and there; then they would show to more advantage also. The *Dahlias* especially should be liberally top-dressed with rotten manure. The single-flowered and the Cactus-flowered *Dahlias* are the best to plant, but the show varieties and the *Pompons* are also suitable, especially the latter. All the plants must be first hardened, through exposure to the air in a sheltered position in the garden or a yard, from the second week in May to the end of the month, when they should be planted out, watered and staked. B.

III

A DIAMOND-SHAPED BED IS OFTEN USEFUL IN AWKWARD SHAPED GRASS PLOTS.

GARDENING OF THE WEEK.

FOR SOUTHERN GARDENS.

Plants Under Glass.

Callas.—Now that flowering has ceased, stand the plants out of doors in a sheltered position to ripen and rest.

Hybrid Winter-Flowering Begonias.—As the young growths become large enough on the old plants, insert them in small pots in a sandy mixture of loam, leaf-mould and peat, and plunge in the propagating-pit until rooted.

Auriculas of the show and alpine varieties, after the flowers are past, should receive their annual potting. Use thoroughly cleaned, well-drained pots and a compost of good fibrous loam, with a little flaked leaf-mould, some cow or sheep manure, and finely-broken brick and coarse sand. If it is desired to increase the stock, all offsets should be detached and potted up. During the summer months give them a position shaded from the sun, but where all the light and air possible can reach them.

The Kitchen Garden.

Thinning the Crops.—This must be done before the young plants get too large. At the earliest thinning the straggling seedlings should be removed. With Carrots, if not too severely done at the first, the young roots at the second thinning will be useful for kitchen purposes. Onions, where size is not important, are best not thinned, excepting just a few pulled for use. They then ripen much better. Keep the Dutch hoe working between the rows.

Mustard and Cress.—For keeping up a supply during the warm weather, select a very shady part of the garden. Make the surface as fine as possible, sow thickly, make firm and water in with a fine-rosed can. Cover the seed-bed over with a board or anything to exclude light until well germinated. Sow little and often.

Potatoes.—As these appear above the ground, keep drawing soil around them for protection, as there is yet time for late frosts. Keep the hoe at work between the rows.

Peas.—Sow more Marrowfat varieties for succession, preferably in trenches, as then better facilities are afforded for supplying copious waterings in dry weather.

Turnips.—Make another good sowing of one of the white varieties.

The Flower Garden.

Antirrhinums.—These must be well hardened off before planting out in the course of a week or two. For bedding arrangements they are admirably suited, coming true from seed, and are also to be obtained in varying heights for different purposes and positions. The giant, intermediate and dwarf are each alike excellent, the latter especially useful for ribbon borders.

Agaves.—These should be well sponged and syringed before being placed out of doors. The same applies to Bays and Myrtles.

Window-Boxes.—Have these thoroughly repaired and cleaned, so that everything is in order for the plants when the time for planting arrives.

Border Chrysanthemums.—Plant out now in well-prepared ground. Either a mixed border or a break may be planted, putting the plants out in rows, and where many cut flowers are in request, this is to be recommended. The early-flowering varieties should always be selected, as the late ones, in the event of wet, cold weather, are not to be relied upon. The varieties are numerous, but a few of the best are Kitty Riches, Harvest Home, Roi des Blancs, Goacher's Crimson, Polly, Mme. Desgranges and its sports.

Pentstemons.—These can be planted out now with safety. A slight frost will not harm the plants, if such occurs, providing they have been hardened off.

The Hardy Fruit Garden.

Strawberries.—The beds will now require a good layer of straw to be placed round the plants. See that this is well worked round them, so that the flower-spikes are kept clean. Any runners that may be appearing, if not wanted for propagation, should be cut off.

Gooseberries.—Keep a sharp look-out for the Gooseberry caterpillar. If allowed to go on unchecked, the bushes will soon be completely defoliated. For a remedy dust with Hellebore powder, or syringe in the evening with a good insecticide. Red spider is another great enemy. Vigorous syringings and waterings at the roots in dry weather and the use of an insecticide will do much to mitigate the attacks. The mildew now so prevalent in some parts should be notified to the Board of Agriculture if there is any suspicion of its presence.

Fruits Under Glass.

Early Melons.—The earliest fruits will now be ripening, and to get the best flavour the finishing of the fruits should be assisted with a free circulation of air, drier conditions and a little fire-heat in the pipes through the night. Before going to table the flavour will be improved by the fruits being placed upon a sunny shelf.

Successional Plants.—As the fruits commence to swell and the crop is selected, support the fruits either with nets or flat, square pieces of board with a string passed through each corner. Keep a warm temperature, but air freely in the morning when the weather allows, closing early and taking advantage of the sun's rays. Water at intervals with liquid manure, properly diluted, while for a change a sprinkling of a quick-acting patent manure can be well watered in. If the stems show any signs of canker, dress the affected parts with lime. When watering, avoid wetting the stems of the plants near to the soil. While the fruit is swelling, syringe twice daily and keep the laterals removed before they get too strong.

Damping.—To keep the foliage of the occupants in houses in a healthy condition, this plays an important part. The floors, walls, borders, and especially under the pipes, should be damped at least twice daily. At this season warm houses benefit by having the floors at least damped each evening, and an occasional sprinkling of manure-water does much to quell attacks of spider.

E. BECKETT, V.M.H.

Aldenham House Gardens, Elstree, Herts.

FOR NORTHERN GARDENS.

The Fruit-Houses.

Strawberries.—These will now come on very well in cold frames, but it is not the best practice when ventilating to do so from the upper and under parts alternately. It should be done only from the upper part, which prevents draughts and their concomitant mildew.

Cucumbers.—Plants should be prepared for planting in pits, in which they succeed during the summer months without fire-heat, provided all the sun-heat possible is caught and moisture not unduly applied. They may be planted either in large flower-pots or, preferably, in wooden trays not more than a foot deep.

Tomatoes.—These do splendidly when planted out in unheated structures. They will need hardly any ventilation for several weeks, and if the soil is in the right condition, no water need be applied till the first fruits are set. They should not be planted closer than 3 feet, and be grown on single stems, to be stopped beyond the third truss. If more is left, the fruit has not time to mature.

Late Peaches.—It will not be necessary from this date ever to close the houses, that is, if the crop is wanted to be as late as possible in ripening. The trees ought to be thoroughly washed twice daily as a precaution against red spider. It sometimes happens that trees in robust health produce fine-looking, strong shoots near the central parts. These, as a rule, are worthless, and if not wanted to fill bare spaces should be forced off. If wanted, pinch them near the base in order to cause one or more less strong but valuable shoots to break.

The Vegetable Garden.

Leeks.—Frame-raised Leeks are now large enough to plant out in narrow trenches. They will need protecting for a few weeks till established.

Curled Kale.—In the course of the next few days a full sowing of this valuable vegetable should be made. Strains vary considerably in hardiness, those

that are dark green being usually the hardier. Though many people sow much earlier, it is not essential, and when sown at this time the young plants come in right to follow Potatoes and other crops.

Endive.—If Endive is wanted in early autumn, a few seeds of a curled variety, which is to be preferred to the broad-leaved, may also be sown at the same time; but it is too soon to sow for the main winter and spring crops. Endive, unlike Lettuce, does best in rather firm soil, and should be transplanted when the seedlings are still small.

Rampion.—This, too, ought to be sown, very few, if any, plants running to flower when sown so late, and there is plenty of time for the roots to grow. The minute seeds should scarcely be covered. A deep enough depression for the seeds is produced by pressing a garden line into the smooth soil, and drawing the back of a spade over the surface serves to cover the seeds sufficiently.

The Flower Garden.

Bulbs.—Those in beds to be shortly occupied with summer-flowering plants should be lifted and laid in the reserve garden to finish growth.

The Bog Garden.—A constant supply of water must now be provided for bog plants, which are growing very rapidly. Some plants, e.g., Forget-me-not, Sagittaria and Bogbean, grow so rank that unless they are curtailed at the beginning of the season, the less pushful plants are crushed out of existence. Others, such as Primula japonica, produce so many seedlings that it is necessary to treat them almost like weeds.

The Wild Garden.—Sweet Cicely (Myrrhis odorata), Polygonatum, Holy Thistles, Bocconias and others are now furnishing this special garden. It is to be noted that it may be too wild, and, as in the bog garden, a judicious thinning out of those which would otherwise encroach on their neighbours must be made from time to time. Nor should common weeds be permitted to obtain a footing.

Climbers.—These quickly get entangled if left to Nature, while if occasionally attended to, so that the shoots are made to take the proper direction and superfluous ones removed, the general condition of the plants is improved. Many of the wickuraiana Rose varieties produce far too many shoots from the base, and now that it is possible to pick out the best, the others may be broken off before they become set. Banksian Roses are showing an abundant bloom, but these are not so profuse in pushing new shoots, and therefore all that do push should be preserved and duly trained.

Rosa hemisphaerica.—This very old but beautiful species has obtained a dubious reputation, on account of its obstinate refusal to carry flowers. Here it flowers profusely, and at the present time the long shoots have to be denuded of a large number of buds to strengthen those that are left to expand. Its other requirements consist in cutting out the flowered-out shoots and thinning the weaker of those of the current year's production.

The Plant-Houses.

Ficus repens is a capital plant for covering walls of stoves, but it must be trimmed frequently to keep it neat. There is a small-growing variety of this.

Deutzias.—The value of the common *D. gracilis* for greenhouse decoration has long been recognised, and it can now be supplemented with many distinct and pretty forms, such as *D. Lemoinei compacta*, *D. gracilis venusta*, *D. Vilmorina* and *D. Boule Rose*. They vary considerably in habit, but all are useful. Long shoots can only be produced by hard pruning after flowering.

Pelargoniums.—The earliest of these showy plants are now coming into bloom, and it would be advisable to subject them to a mild fumigation before the flowers open. Given a sufficient supply of water at the root with manure, aphid will not be troublesome. Propagation may successfully be carried out now with flowerless shoots, which root freely, one cutting in a 2½-inch pot. They require a little higher temperature than that of a greenhouse, and very little water till roots are produced. These grow into very nice plants for flowering the following year.

Tynningham, Prestonkirk, N.B.

BOOKS.

Turner's Water-Colours at Farnley Hall.—

Those of our readers who appreciate good pictures will be familiar with the many beautiful oil-paintings by Turner that are to be found in the National Gallery and the Turner Gallery at the Tate Gallery; but his water-colours, of which there are a considerable number in existence, are not nearly so well known, mainly because the

A TERRACE GARDEN IN THE MAKING BY MESSRS. WALLACE AND CO. AT THE FORTHCOMING INTERNATIONAL EXHIBITION. IT COM- PRISES AN OLD ENGLISH GARDEN, LILY POND AND A CASCADE.

best are in private collections. At Farnley Hall there are nearly two hundred water-colours by this famous artist, and the present owner, Mr. F. H. Fawkes, has kindly placed these at the disposal of the editor of the *Studio* for reproduction. Thirty pictures in all are to be published, in five parts, each part to cost 2s. 6d. In Part I., which we have before us, we find Bonneville, Savoy, an exquisite piece of mountain scenery; The Valley of the Wharfe from Caley Park; The Valley of Chamounix; Scarborough Town and Castle: Morning; Boys Collecting Crabs; and Interior of St. Peter's, Rome. These reproductions are exceptionally good. Each plate measures about ten inches by seven and a-half inches, and the sunk mounts 16 inches by 14 inches. The respective parts are to be published by the *Studio*, 44, Leicester Square, London, W.C.

The Gardener and the Cook.*—The authoress of this book has conveyed much very useful information in a most charming style. Every item of information is, as it were, served to the reader, with a few words of complement. There is no serious attempt made to give cultural hints on the different vegetables and herbs dealt with in the book; but some references to the vegetable and fruit garden are very instructive. For example, the authoress says, referring to the cultivation of Mushrooms, "Our Mushroom-bed is made up in a shed that covers a north wall, and is on a slope. It is a dry, well-built shed, and is only used for storage of roots. The bed itself is made of horse-droppings intermixed with loam. . . . It is watered with a fine rose and rain-water, frequently enough to keep it moist; for do not the ordinary field Mushrooms come best in a damp season? They will not flourish in a dry soil, or when they are cold, and it is of no use attempting to make them do so. . . ." The chapter on salads is very interesting and instructive; but

here, again, it is not of their culture, but of the preparation in the kitchen that the information refers to. Herbs and their uses are ably dealt with; and the chapter about recipes and the use of butter should be well studied by the cook. The authoress speaks of Lettuces, Cos or Cabbage, cooked, and says, "One of the nicest dishes we can have in summer is that of Lettuces stewed in broth and served hot with a garnish of Green Peas or young Beans. After being washed and cut

into half, the Lettuces are thrown into boiling water with salt to blanch them, then lifted out and drained. . . ." The whole process is simple and interesting, and the reader will find that the foregoing quotations from the book are a sample of many paragraphs written in an equally delightful style. The distinction between plainly-cooked and plainly-dressed vegetables, with the *raison d'être* of sauces and dressings; of tender greens, of Gourds, Marrows and their kind; of Celery, Artichokes and Potatoes; the treatment of Beans and dried vegetables; of Corn, Rice and Italian pastes; fruit for the table, the store-room and closet; preserves, jellies, bottled fruits,

pickles, wines and cordials, are all dealt with. The black-and-white illustrations add interest to the book, which should be read by all housewives and others responsible for the preparation of vegetables and fruits for the table.

Oxford Gardens.*—All students of history and our ancient monuments owe a debt of gratitude to the author of "Oxford Gardens" for the excellent account he has furnished of the famous Old Physick Garden and the other various College gardens of Oxford. England's oldest existing botanic garden was founded as long ago as 1621, which the author points out upon what appears indisputable evidence is a decade earlier than most writers fix its foundation. To thoroughly appreciate the part played by this classical institution in early botanical science in this country, one needs to carry his mind back in review of the period about which it came into existence and note the wonderful impetus that science received during this century, when, having emerged from the devastating effects of the Civil Wars, its learned men settled down to the pursuit of those subjects whose victories are more glorious than its wars. It was during this period that we get the foundation of the Royal Society by Bishop Wilkins, also at Oxford. Hooke was at work improving the microscope; Boyle, the air-pump. John Ray raised zoology to the rank of a

* "Oxford Gardens," based upon Daubeny's Popular Guide to the Physick Garden of Oxford: With notes on the gardens of the Colleges and on the University Park, by R. T. Günther, M.A., Fellow of Magdalen College, Oxford. Price 6s. net. Oxford: Parker and Son. London: Simpkin, Marshall and Co.

science, while his "History of Plants," coupled with the work of Robert Morison, the first Professor of Botany at Oxford, may be said to be the foundation of modern botany. To Nehemiah Grew and Malpighi, who divided the honours, may be ascribed the foundation of the study of vegetable anatomy.

The historical part of the book is very fascinating, and gives interesting details about its famous professors, many of whom have left their mark on botanical science, as will be realised when, besides Morison, already mentioned, names are recalled such as Sherard, the founder of the Chair of Botany; Jacob Bobart, the younger; Dillenius, the author of the classical work, "Hortus Elthamensis"; Sibthorp, father and son; Daubeny, the beloved of his students; Bayley-Balfour, who now presides with such distinction over the Edinburgh Garden; and the present holder of the professorship, Dr. S. H. Vines.

The work is well planned, and has chapters on the trees, shrubs and wall plants, which contain interesting details of famous trees; and on hardy herbaceous plants, which describe the various arrangements which have existed in the garden and the plan adopted at the present time, with a description of the various Natural Orders, which students to-day must find of great value. Hardy aquatics, for which Oxford has been famous from the time of the elder Bobart to our own day, are also dealt with. The transition of the greenhouses is also described from the very earliest time, when the greenhouse was nothing more than a dignified barn with massive walls, which were, no doubt, useful in absorbing the sun's rays during the day and radiating them out during the night. A very crude method used in heating the greenhouse during frosty weather is shown in a figure of a four-wheeled open iron waggon, which was filled with burning charcoal and drawn through the house by the gardener. What a contrast to the present light modern structures with their efficient methods of heating!

The contents of each of the present greenhouses are well described, and mention made of the various

MESSRS. PULHAM AND SON'S ROCK AND WATER GARDEN IN THE MAKING AT CHELSEA. THIS DESIGN EMBRACES A SERIES OF WATERFALLS AND A MORAINÉ GARDEN.

economic and other uses of the plants. Special mention may be made of the Water Lily House, the occupants of which and their cultivation by the present curator have brought great credit to the garden. How thorough is the work of the author may be seen by the inclusion of chapters on the weeds and wild plants, the botanical museum, library and laboratories, which detail

* "The Gardener and the Cook," by Lucy H. Yates; price 3s. 6d. Constable and Co., Limited, London. 1912.

the origin and varying fortunes of each. Lists of plants growing on the various walls are given, which makes the work a useful guide-book. There are a few misspellings of plant names, which will, no doubt, be altered in future editions. The last part of the work chiefly deals with the trees in College gardens, and contains an excellent index, which facilitates ready reference.

ANSWERS TO CORRESPONDENTS.

RULES FOR CORRESPONDENTS.

QUESTIONS AND ANSWERS.—*The Editor intends to make THE GARDEN helpful to all readers who desire assistance, no matter what the branch of gardening may be, and with that object will make a special feature of the "Answers to Correspondents" columns. All communications should be clearly and concisely written on one side of the paper only, and addressed to the EDITOR OF THE GARDEN, 20, Tavistock Street, Covent Garden, London, W.C. The name and address of the sender are required in addition to any designation he may desire to be used in the paper. When more than one query is sent, each should be on a separate piece of paper. Plants for naming should be clearly numbered and securely packed in damp grass or moss, not cotton-wool, and flowering shoots, where possible, should be sent. It is useless to send small scraps that are not characteristic of the plant. Letters on business should be sent to the PUBLISHER.*

FLOWER GARDEN.

VIOLET SPOT DISEASE (B. A. I.).—Various causes produce spotting of Violet leaves; but if, as seems possible from the symptoms you describe, the spotting is due to a fungus, probably the best treatment (always provided a sufficient circulation of air is provided for) is to spray the plants, say, once a week, with a solution of loz. of potassium sulphide in three gallons of water.

SUMMER BEDDING (M. T.).—The only yellow-flowered plants we recall suitable for association with the Salvias as bedding plants are tuberosus Begonias of that shade. You might, of course, have raised yellow-flowered Antirrhinums by special culture, and these latter, indeed, would be the more suitable. Such colour combinations as these require to be prepared a long time in advance, and to be worked up to accordingly. At this date the Antirrhinums may not be obtainable; hence the Begonias, a profuse-flowering race, would be the best.

VIOLETS (E. W.).—If you require a single-flowered variety of the largest size, you cannot do better than purchase Princess of Wales or La France, either of which is good, the last-named having the largest as well as the darkest-coloured flowers. If, on the other hand, a flower of smaller size would suit, we should recommend well-siana as a good variety, free and very profuse as well as fragrant. Lixonne is also good. Comte de Brazza (white) and Countess of Caledon (lavender blue) are the best of the doubles. The class of plant you require is a well-rooted layer or runner as the season is advancing. On no account be tempted to plant old divided stock, as such material is rarely satisfactory. The ground should be deeply cultivated and rich without undue grossness. The planting should be firmly done and the plants kept from weeds and insect pests, red spider being the worst throughout the growing season.

PEONIES (W. D.).—If the plants were clumps, whether of small or large size, and you planted them intact, you did wrong, and you are reaping as you have sown. The Peony is not a plant to be trifled with. It has a way of its own, and cultivators must, to use a slang phrase, "cotton to it" if they would succeed. The fairly good flowering you had last year was due to the elaborated sap and bud development of a previous year—the thicket of weakened shoots, to which you refer, the outcome of a cultural error you have not confided to us. You can do no good by diminishing the number of these weakened shoots, and it may take years and drastic measures meanwhile before the plants recover. Cannot you give us some further particulars? If so, we may advise you in more definite terms. In any case, let the plants severally alone. The Peony is very impatient of interference at any time, and, when disturbed, certain methods should be adopted if success is to be assured.

POLYANTHUSES FAILING (E. E. F.).—The fault is with the soil, which was teeming with millipedes and much other insect-life of a microscopic nature. Slugs, too, and that most voracious of all, the black slug, were noted. The roots of the plants were quite destroyed. Treat the soil generously with lime, or give a dressing at once and fork it in of any of the advertised soil fumigants. In other ways avoid planting the same crop in the same place each year, remembering that a change of soil to the plant is as clean linen or change of air to human beings. Finally, in so far as the Polyanthus is concerned, raise seedlings

each year, and so always endow your plants with the vigour and freshness of youth.

PEONY BUDS AND ANTS (Hal).—The exterior of the buds of most varieties of Peonies are of a viscid nature, and in all probability the ants find something in it to suit their tastes. It may also be that insect-life in some form is present, and that this constitutes the greater attraction. We have grown Peonies largely, however, but have never experienced disaster from this particular pest. Ants may be kept at bay by the use of carbolic acid in water about the plants, and by dusting the soil with some of the soil fumigants now advertised. Place a little Vaporite in the runs of the ants, or sown thinly over the soil it has a deterring effect. In all probability your Peonies have suffered not from the attacks of ants, but either from frost or the prevalence in some seasons of a fungus which attacks the stems a little below the flower-buds. As you give us no definite information respecting the damage, we can form no opinion thereon.

TREES AND SHRUBS.

PLANTING CAMELIAS (P. M. S.).—Camellia trees may be obtained from Messrs. William Paul (Waltham Cross), Limited, The Royal Nurseries, Waltham Cross, Herts. The present is a good time to plant them, especially if they are obtained in pots. Before planting, be careful to prepare the ground well by trenching, and if heavy, by adding lighter soil. Whether the soil is heavy or light, the trees will appreciate a little peat placed about the roots at planting-time.

PRUNING A RHODODENDRON (A. E. P.).—The present is the best time to cut a Rhododendron hard back. You may prune the branches back into old wood, for, as your plant is growing in a pot, you can place it in a warm and moist house to encourage new growth. After cutting back, keep the branches well syringed several times a day. This will encourage dormant buds to break into growth. Do not disturb the roots of the plant at the present time. Should any rotting be necessary, leave it until the new shoots are 1 inch or 2 inches long.

TREES AND BRACKEN (A. M.).—The following kinds of trees would be suitable for your purpose: Sycamore, common Elm, common Oak and Beech. Early spring, February or March is a good time to undertake the transplanting of Bracken. You must, however, be prepared for disappointing results, for although Bracken makes itself a pest in many places, and rapidly covers the ground where it is not wanted, it is sometimes most difficult to establish it elsewhere. The best plan is to obtain large turves containing Bracken rhizomes, and plant them bodily in the place where the effect is desired. The most satisfactory time to transplant Oriental Poppies is autumn, winter and early spring. They would not be likely to do any good if moved now. You cannot do better than plant the following subjects against your wall with a northern aspect: Crataegus Pyracantha, Ampelopsis Veitchii, Jasminum nudiflorum and Celastrus articulatus. Ivies of various kinds are, of course, the most satisfactory plants for north walls; but those you object to.

FRUIT GARDEN.

INJURY TO GOOSEBERRY BUSHES (W. J. C.).—There is no disease of Gooseberries likely to produce the result of which you speak. If birds are the culprits, you will find the bud scales, as a rule, still left on the branches, while all the soft parts of the bud have been destroyed. It is probable that birds have been at work. Black cotton, threaded over the bushes during the winter, is often a good preventive of damage of this kind, and delaying the pruning until February is also a good measure. Limiting the bushes may also be carried out with advantage.

PEACH TREES DROPPING FLOWER-BUDS (L. H. R.).—Seeing that you have been successful in the growth of your trees in pots for some years, it is not easy to give a reason why they have failed this year, without seeing the trees and knowing something of the local conditions under which they are grown. There have been many complaints this spring of Peach and other fruit trees in pots, as well as pot-forced Strawberries, and even Grapes in established borders, proving to be in a poor and unsatisfactory condition in consequence of the great heat and long-continued drought of last year having exhausted and weakened the trees. We suggest that this may be the cause of the failure also in your trees. If so, it may prove not to be an unmixt evil, as during the rest from carrying fruit the trees will have will, no doubt, greatly benefit them for next year's fruiting.

PEACH BLOOM DROPPING (Tudor).—The cause will very likely be found in keeping the plants too warm in winter. Trees at this time should be kept as cool as possible. One seldom or ever finds the blossom fall from trees grown on walls in the open air. Possibly the roots have also been too dry at one time or another. Dryness at the root is fatal to the well-doing of a Peach tree; or it may be that your soil is deficient in lime, or perhaps the drainage is at fault. (2) The most common cause of late Pears shrivelling is because they are gathered too soon. Keeping them in too warm and dry a place will have the same effect. (3) The Cherry you mention would succeed very well in the position. It would be better to plant two fan-trained trees, one on each side of the window, rather than cordon trees, as the Cherry succeeds best when permitted to grow without too much restriction. *Re Pear blossom.*—Yours must be a fine sight. We hope you escaped the destructive frost of Friday morning, April 12, 17, in some places, which completely destroyed Pear and Plum tree blossom.

KITCHEN GARDEN.

ASPARAGUS-BED GONE WRONG (Asparagus).—There are so many causes which may be accountable for the failure of Asparagus-beds that, in the absence of some particulars to guide us to a conclusion, it is difficult to give an answer which may prove useful. You say the position is low, and possibly the ground cold and not too well drained, and the soil perhaps heavy as well. These conditions, if present, are sufficient to account for the trouble. A frequent cause of failure is cutting the "grass" too hard and for too long a time. If this is persevered in for a few seasons, it will soon prove fatal to the Asparagus. You will know whether this has been the cause in your case. In cutting Asparagus the best way is to cut all the grass that comes, large and small, until June 20, when cutting must be stopped altogether for that season. The best thing you can do is to give the bed a dressing of bonedust at the rate of a small handful to the square yard. Do not cut hard this summer, and not at all after the above date.

CUCUMBERS AND ARTIFICIAL MANURES (Scots).—As a top-dressing for Cucumbers planted out in beds in the ordinary way, for the purpose of encouraging roots, we know nothing better than the following: To one peck of good virgin loam, passed through a 1-inch meshed sieve, add a gallon of fresh horse-manure (passing this through a sieve in the same way), three-parts of a pint of bone-meal, and about the same of soil. Mix well together and place firmly over the bed half an inch deep, having previously taken off some of the old surface soil. Liquid manures.—The best results are obtained by occasionally varying these. One of the best is Fernvian Guano, dissolving half a pint in two gallons of water. Pearson's, Clay's and Thomson's manures are excellent for this purpose if carefully applied according to instructions as to quantities to use. Soot-water is excellent used in the same proportion as the guano, as also is the liquid from stable and cow yards when sufficiently diluted. Our experience in the use of liquid manures goes to show that they are generally used in too strong a solution, with a weakening instead of strengthening effect on the plants to which they are applied.

TO MAKE AN ASPARAGUS-BED (A. S.).—The Asparagus loves a deep, rather sandy or open loam to grow in, because such soil is always well drained and warm; but any soil can be made to grow Asparagus, provided the labour and expense of preparing the ground is not begrudged, and it should not be, as, once a bed is well formed and planted, it will remain in profit for a lifetime if well looked after. Cold, heavy, wet soil is the worst for this plant. We will take it for granted that your soil is ordinary, well-drained garden soil. An Asparagus-bed should be 4 feet wide, with a path or alley on either side each 2 feet wide. It will thus take a piece of ground 8 feet wide to form an Asparagus-bed; but if two beds are formed side by side, 6 feet more only is required for the next bed, as the one alley will answer for one side of each bed. Let the land be trenched 2½ feet deep (the alleys to be trenched as well, as the Asparagus plants will soon root into them). In trenching keep the poor soil to the bottom, and keep a wide trench open while trenching proceeds (at least 18 inches). Into every trench should be placed a liberal quantity of rich farmyard manure. The soil cannot very well be too rich as long as the manure is well mixed with the soil. There should be at least a full earload to every rod of ground, including the alleys. Having finished the trenching, mark out your bed or beds, each 4 feet wide, and then lay the Asparagus roots on the surface of the soil (not planted in it). There should be three rows of plants to each bed—a centre row and one on each side of it, at 15 inches apart. There should be 10 inches between plant and plant in the row. Conover's Colossal is one of the best varieties. One year old seedlings are the best to plant. Keep the bed free of weeds during the summer, give it a light dressing of partly-rotted farmyard manure after the grass is dead, and clear it away in the autumn. Do not cut any young grass until the third year after planting.

MISCELLANEOUS.

CLIMBERS AND GARDEN SWING (F. H. R.).—You will find Crimson Rambler the best Rose to train on the poles you describe. The wichuraiana varieties would be less suitable on account of their rampant growth. Do you not think, however, that the spines of the Roses would be rather dangerous for children playing in the vicinity, especially during summer, when the plants were growing fast and the swing in regular use? To our mind Clematis Vitalba would be a more suitable subject for the position. It grows well almost anywhere, and will stand wind.

HELIOTROPE FOR INSPECTION (Five Years' Reader).—We can detect nothing radically wrong with the shoots of Heliotrope sent; but, judging from their drawn and attenuated appearance, they have evidently been grown of late in too high a temperature. A minimum of 50°, running up to 60° during the day, is very suitable for Heliotrope during the winter months. To get rid of ants, pour boiling water in every crevice where they take shelter; that is, when it can be done without injury to the roots of any plants. Next, they can be trapped by smearing pieces of sponge with treacle, and when these are covered with insects they may be dropped into boiling water. Bones are also effective as traps, and may be treated in the same way. For the destruction of beetles you may employ Beetlecure or phosphorus paste, or they may be trapped by putting a little beer or sugar and water into deep earthenware dishes, into which they will get, and are then unable to extricate themselves. Care must be taken to place a few pieces of wood leaning against the dish in order to allow the pests easy access. Keating's Powder, too, will stupefy the beetles, and it is not injurious to the roots of plants. In any case, perseverance is an important factor in getting rid of both of these pests.

EDITORIAL NOTICES.

Every department of horticulture is represented in **THE GARDEN**, and the Editor invites readers to send in questions relating to matters upon which they wish expert advice.

The Editor welcomes photographs, articles and notes, but he will not be responsible for their safe return. All reasonable care, however, will be taken, and where stamps are enclosed, he will endeavour to return non-accepted contributions.

As regards photographs, if payment be desired, the Editor asks that the price required for reproduction be plainly stated. It must be distinctly understood that only the actual photographer or owner of the copyright will be treated with.

The Editor will not be responsible for the return of artistic or literary contributions which he may not be able to use, and the receipt of a proof must not be taken as evidence that an article is accepted. Publication in **THE GARDEN** will alone be recognised as acceptance.

Offices: 20, Tavistock Street, Covent Garden, W. C.

NOTES OF THE WEEK.

To Our Readers.—In this special issue, which is more than twice the ordinary size, will be found a comprehensive descriptive report of the great Royal International Horticultural Exhibition. In a show of this magnitude, where there are over one thousand competitive exhibits, as well as over a hundred non-competitive groups, it is obviously impossible to report it in the ordinary way, so we have adopted the plan of giving descriptive illustrated articles of each section. Next week we hope to publish particulars and illustrations of the new plants which receive awards or certificates. Those readers who have gardening friends abroad should post them a copy of this week's issue. We shall be pleased to welcome readers at our kiosk, which is in the central avenue of the exhibition grounds and opposite the administration offices.

Adenocarpus anagyris.—This is a rare plant and a conspicuous evergreen, and the habit of growth and the manner in which the leaves clothe the growth arrest attention. It is a fast grower, attaining 6 feet to 8 feet in about three seasons. The flowers are a golden yellow. The plant can be easily raised from seed.

The Japanese Orange, Limonia trifoliata (Ægle sepiaria), is very striking and beautiful just now; it is covered with a mass of white flowers, which later on produce small Oranges. The branches are armed with long spines, and these give it a very conspicuous appearance when in bloom. It is not at all particular as to soil, growing in ordinary heavy soil or that of a light nature. It likes plenty of water, particularly in dry weather.

A Showy Japanese Crab Apple.—Should a showy bush or small tree be required for the shrubbery or lawn, no mistake can be made if the Japanese *Pyrus floribunda* is selected, for it is aptly named, as no tree blossoms more profusely or more regularly. Very often met with from 12 feet to 15 feet high, it forms a wide-spreading head upwards of twenty feet in diameter, with branches sweeping the ground in all directions. The rose-flushed flowers appear during late April and early May, and they are in such profusion as to almost hide the branches. A variety called *atrosanguinea* may be obtained. This is recognised by its rich red flowers, which are even more noticeable than those of the type. Where space is available, a pretty effect may be produced by forming a group of the two forms. Such a mass is to be seen at Kew occupying a mound, with a few taller-growing conifers, near the Water Lily House. In another part of the Gardens a clump of the same *Pyrus*, with groups of Pheasant's-eye Narcissus beneath, is also very attractive.

The Horticultural Club.—A special meeting of the club was held on Tuesday, May 14, to hear a lecture on the Canadian Rocky Mountains by Mrs. Henshaw. The attendance numbered upwards of fifty, including many ladies. Mrs. Henshaw took her hearers on many expeditions, and illustrated by beautiful language and scores of exquisite slides all the features of interest. It was a gathering of remarkable success, and all present were heartily grateful to the speaker for coming among them. The chair was occupied by the president of the club, Sir Frank Crisp.

A Beautiful Honeysuckle.—*Lonicera alpigena* belongs to the bush section of the genus, and is easily distinguished from other members of the same group by its upright habit, intensely hairy leaves and showy inflorescences. A native of the European Alps and the Himalaya, it forms a shapely bush 6 feet or 8 feet high and as far through, clothed with ovate or obovate leaves, which are densely covered on the under surface with soft, velvety hairs. They vary from 2 inches to 4½ inches long and from 1 inch to 2 inches in width. The flowers are borne in pairs from the leaf-axils, each two flowers being enclosed by a pair of large red bracts. The flowers are orange-coloured, tubular, half an inch to three-quarters of an inch long and hairy. The bracts are persistent after the fall of the flowers, and gradually take on a deeper colour, so that when the black fruits are ripe in August they are deep red. Growing freely almost anywhere, it is an excellent shrub to place in a mixed shrubbery, while there are many less ornamental subjects which occupy prominent positions as specimen plants.

Conferences at the Royal International Horticultural Exhibition.—Two important conferences will be held during the International Exhibition at Chelsea on subjects connected with horticulture. Both will be presided over by the Right Hon. A. H. Dyke Acland, chairman of the science and education committee, and will be held in the Recreation Hall of the Chelsea Royal Hospital. Admission is free, and all interested in the subjects are cordially invited to attend. Those attending the exhibition may enter the conference hall from the exhibition grounds (gaining re-admittance to the exhibition by the same means). Those not attending the exhibition may enter the conference room from the Royal Hospital entrance. The first conference will be on Thursday, the 23rd inst., at 2 p.m., the subject being "Horticultural Education." The second conference is arranged for Friday, the 24th inst., at 9.30 a.m., on "Legislation in Connection with Plant Diseases and Pests." Reports are being prepared by the science and education committee on the present condition of both horticultural education and legislation against plant pests, and will be printed with the papers and discussion.

CORRESPONDENCE.

(The Editor is not responsible for the opinions expressed by correspondents.)

Fritillaria Meleagris.—I was pleased to see the Soake's-head Lily figured in *THE GARDEN* for May 11, page 231, as growing; but I think it is not nearly enough known and appreciated as a cut flower for the house, where it shows to the greatest advantage. I frequently use it in this way, and find its quaint shape, colours and marking always attract attention and admiration. It makes a dainty table decoration in Venetian glass, which suits it best of all; but as this is not generally obtainable, the next best is, I think, bronze Bretby ware.—AN AMATEUR.

Cottage Tulip Grenadier.—Some years ago Messrs. Wallace and Co. of Colchester put a beautiful collection of new seedling garden Tulips on the market, of which I consider Beau Brummei, Marksman and The President to be the pick. Grenadier, I believe, comes from the same source, and is a great beauty. Like Mrs. Berkeley, of which I was kindly given a bulb two years ago, it is an immense rich orange scarlet self, with a striking yellow base, of medium height. I measured one of the blooms at Vincent Square, and it was 4 inches long. It received a unanimous award of merit from the Narcissus and Tulip committee on April 30.—J. JACOB.

Coronilla glauca Outdoors.—This plant, about which several notes have recently appeared, thrives out of doors here. Enclosed is a photograph of one planted in October, 1909, from a thumb pot. It is now 5 feet 6 inches high, and has a spread of 6 feet 6 inches. It has had no protection during the winter and has been in full flower since January last and is only now going off.—R. COTTON, *Llwynon, Llanfair P.G., Anglesey.* [Unfortunately, the photograph was not sharp enough for reproduction.—ED.]

— I notice in *THE GARDEN* of April 20, page 189, and May 11, page 226, notes on *Coronilla glauca* flowering outdoors. My employer, the Right Hon. A. H. D. Acland, has one in full bloom on a west wall. It has been in bloom since December more or less, and is now a sheet of yellow. It is 7 feet high and about four feet wide. We have also a bush 2 feet high and about three feet through on a south border. These have had no protection, and appear quite hardy. It is a most desirable shrub. Mrs. Acland thought this might be of interest to your readers.—G. BATTY, *The Gardens, Dunkery House, Felixstowe, Suffolk.*

Fruit Trees for Garden Effect.—Your correspondent Mr. Wakely, page 215, issue May 4, raises a very interesting and sensible question about planting fruit trees for floral effect. Well-blossomed fruit trees are, I think most people will admit, magnificent sights, whether in small or large gardens. I can see as much real beauty—more, in fact—in a nicely-laden Apple bush of pink and white flowers, or a Pear with creamy white, than in many of our extolled usual garden plants. Coupled also with the pleasing show of the fruit blossoms is an ingratiating fragrance such as many border or pot plants never yield. For two or three years past we have, at Ken View Garden, Highgate, practically adopted the "effect" method with bush Cherry trees, not because the fruit is not wanted, but on account of the difficulty in protecting the trees from the birds when the fruit is ripening. Having attained rather

large proportions, the trees are not easy to net; consequently, very few Cherries reach maturity. But the trees are to be kept for their floral spring loveliness. Of course, I am not suggesting we need not trouble about fruit.—C. TURNER.

Choisya ternata.—I was much surprised just recently to meet with a very large specimen of this sweet-scented evergreen shrub growing in a somewhat cold, exposed position in our public gardens here. It is evident that when planted it was done in an error or sort of chance that it might live or die. In any case, no other one is in all the gardens. When introduced here from Mexico early last century, it was treated as a stove plant; but for many years, planted outdoors, it has been so done in very sheltered positions, usually on the south side of buildings. I regard the example I refer to here as showing that it is really quite hardy, and should have a position in the shrubbery of full exposure. The plant, which has been for some time literally a mass of pure white flowers that emitted very rich perfume, is some six feet in height and seven feet through. As seen here full of hard wood that bears no evidence of injury from weather, I should regard this *Choisya* as one of the very finest of all our early-flowering shrubs.—A. D., *Kingston.*

Showing English Daffodils in America.—I read with great interest in the Rev. Joseph Jacob's "Daffodil Notes," page 208, April 27, "What About America." Once again this well-known gentleman has given a most valuable hint to Daffodil raisers and growers in pointing out a new opening for this lovely spring flower. The taking of a collection such as we often see at the Royal Horticultural Society's Hall would create surprise and find new roots in the hearts of the Americans. I think the difficulty in getting the flowers across the Atlantic can be overcome. The varieties selected should be well watered, which will help to strengthen the flowers. Shade them well even before there is any sign of the flowers showing colour. Cut them very young, as we all know they will fully develop in water. Tie three flowers together, get some damp moss and cover the stems from bottom to top about one inch off the flowers, and about one inch off the bottom, fasten it with raffia, and then get some paper and place it over the moss so that the damp does not strike the flowers. I should be glad to hear more on this important subject.—J. SHNEIDER, *Bewdley Hill, Kidderminster.*

Roses with Beautiful Foliage.—I think Fellenberg should take its place among the Roses valuable on account of their decorative foliage. It has many other virtues. I have a bed of it this year making promising and beautifully-coloured growth. May I add how much pleasure Mr. S. Arnott's note on *Fritillaries*, page 231, issue May 11, gave me. I have groups in my wild garden which are always much admired, and especially one rising from a carpet of white Periwinkle. They have the merit of constancy. I have one or two bulbs, white, which were collected near the Thames by a friend nearly twenty years ago, and which come up every spring in an uncared-for part of the garden with astonishing persistency.—ELLEN E. STEVENSON, *Stoke Poges.*

— The very interesting article on this subject and the comments on Mr. Darlington's paper on page 228, issue May 11, will cause many readers to reflect deeply on the subject. Both hews, foliage and wood of some of our cultivated Sweet Briars are very beautiful in combination, and I have used them largely

on pillars in the garden. The side branches, when cut and placed in tall vases as soon as the fruits are fairly well coloured, look charming. I used to cut back the side shoots freely every year in this way. Another lovely Rose, Mme. Berard, yields many flowers in the autumn, and at the same time the young foliage is exquisite. If placed in water in a dark cellar for one day and night, it will remain fresh much longer than if cut and placed in the vases forthwith. The foliage of Dorothy Perkins in some seasons is very beautiful, and may be cut at times with clusters of late flowers.—SHAMROCK.

Exhibiting Daffodils.—Perhaps as an exhibitor of long standing, I may give my experience on this subject, for what it is worth. It is no easy matter to cut and pack and bring 1,000 or 1,500 blooms to an exhibition across the (it may be stormy) sea, and subject to railway vibration and the tender mercies of railway porters, and, worse than all, cartage. Mr. Watts, in his letter in your issue of May 11, displays considerable irritation over the paper collars often used by exhibitors to protect their flowers in transit. Incidentally, he pays far too high a compliment to these harmless devices. No paper collar on earth, or even a cast-iron one, will prevent a weak or unsubstantial flower from buckling, and I make a present of the device to all possessors of these undesirable flowers. But what a paper collar may do is to enable the possessor of one or two blooms of some excellent flower which he deservedly prizes, and for which he may have paid a good deal of money, to get them to a show in proper condition and truly representative of the plant. If there are enough flowers of a variety—five or six—they, to some extent, protect one another; but the solitary bloom of one precious seedling is a very different thing, and needs special care and skill in packing, and this is where a paper collar or other similar device comes in, to preserve, not to create, the flower's substance. When flowers have to lie, perhaps for twenty-four hours, in a box exposed to all the adverse conditions I have named as incident to travel, a florist has a perfect right to protect his wares in any way his ingenuity may devise. Florists tie up their flowers when shown in pots with stakes and all sorts of contrivances to mitigate the damaging effect of railway vibration and cartage, and the exhibitor of cut flowers has a perfect right to do the same. Nor do I perceive of what use a "pronouncement" on the subject would be—definite or indefinite—unless an "inspector of boxes," or, rather, an army of such inspectors, were appointed to see that every flower was so packed as to give it a fair chance of being destroyed in transit. The subject of tasteful arrangement is a difficult one, and I personally think if the arrangement does not fall below a certain standard of merit, it had best be left out of consideration in the smaller classes of competitive awards. If an exhibitor brings really fine flowers to a show, I do not think he should be penalised because after a night journey, perhaps, or the very early rising that shows necessitate, his arrangement of his flowers is not quite perfection. I confess my sympathies go out in no small measure to the poor flustered exhibitor who is between the Scylla of price and the Charybdis of classification, and, moreover, has to reckon with some accident which at the last moment obliges him to substitute another flower for one he had intended to stage, and of which he has forgotten both the price per dozen and the classification.—F. W. CURREY.

The Netted Willow.—The note in THE GARDEN, page 213, issue May 4, on *Salix sesquiteria* reminds one of the uses of some of the dwarf members of the genus in the rock garden. The native *Salix reticulata*, for example, is a pretty subject for the shady or, for that matter, the sunny parts of the rock garden in any place where small creeping plants of pleasing foliage are required more than flowering plants, as the garden should have room for both. In *S. reticulata* we have a close-creeping shrub, rising only 1 inch or 2 inches high and having pleasing little roundish leaves, all charmingly veined in a pretty system of reticulation. The little catkins are on long stalks. Although a native of the high mountains of Scotland, it is quite a good plant for the lowlands, and appears to grow in either dry or moist soil.—S. ARNOTT.

Manures to Deepen Colour in Roses.—All who grow Roses in pots and under glass know how difficult it is at times to obtain blooms of the correct colour. Some varieties, especially the yellows, are apt to come very pale in the early stages. *Pelargonium*-growers find sheep-manure a very excellent stimulant, and Rose-growers are also proving this manure to be very good indeed applied as a top-dressing or in liquid form. Most of the older growers relied upon soot in liquid form as an aid to colour, and this, in combination with cow-manure, is still one of the best compounds for stimulating Roses; but I would strongly advise a trial of sheep-manure if it is available. It can be applied in a far more liberal quantity than guanos and such-like, and is much safer to use.—P.

The Century Plant at Kew.—As if to celebrate this eventful year, the largest Agave at Kew has taken the bold step of producing a magnificent flower-spike. It is indeed a bold step and a final one, marking the close of the history of this stately specimen. After flowering its purpose in life will be nearing completion, and the plant will assuredly succumb. Other Agaves lay claim to the title of Century Plant from the fallacious supposition that they flower once in a hundred years, *Agave americana* being the best-known instance. The specimen under notice is that of *Agave atrovirens*. The immense flower-spike is over twenty feet high and is still growing. The thick, fleshy leaves compose a gigantic rosette. The leaves are broad and some six feet in length, each terminating in a formidable spine about two inches long. The species is a native of Mexico. It was introduced in 1860, and is synonymous with *A. salmiana*.

FORTHCOMING EVENTS.

May 27.—Bath Gardeners' Debating Society's Meeting.

May 28.—Wood Green Horticultural Society's Meeting.

May 30.—Manchester and North of England Orchid Society's Annual Meeting.

June 1.—Société Française d'Horticulture de Londres Meeting. Bradford Paxton Society's Meeting.

THE FLOWER GARDEN.

SOME INTERESTING HARDY PRIMULAS.

***Primula cockburniana*.**—This is a Chinese Primula, perennial in its native habitat, but in this country it is difficult to grow as such. It generally dies after flowering, but, given suitable position and soil, a few of the plants may survive from year to year. As it seeds freely and the seed germinates well, it is better to treat it as a

***P. deorum*,** from Bulgaria, is also a bog plant, probably given a good name to help it through life. In my opinion this Primula is not worth the trouble of growing. It is rather rare, expensive to purchase and difficult to grow. The scape, which is from 5 inches to 6 inches high, carries a unilateral, slightly drooping umbel of five to ten flowers of an intense purple violet colour.

***P. Parryi*,** from the Rocky Mountains, is very hardy and superior in every way to *deorum*. It is easily grown, thriving well in the open ground. The scape is from 8 inches to 16 inches high, erect, robust and carries a simple, many-flowered umbel of bright purple, yellow-eyed flowers. Both *glutmosa* and *deorum* should be left alone by the beginner.

Morclands, Duns. JOHN MACWALT.

TULIP NOTES.

Anarchism in Tulipdom.—I must have my annual growl about the naming of Tulips. Every firm and man and woman is a law unto themselves in this respect. Why on earth one firm should buy *Yolande* and then call it *Duchess of Westminster*, and another Mrs. Potter Palmer and call it *Fashion* (as if the Cottage Fashion was not enough), and a third *Goudvinek* and re-christen it *Golden Bronze*, I cannot imagine. This is a sample of what I mean among Cottages and Darwins, and it is just as bad with the early varieties. I happen to know very many of these little vagaries, but it must be aggravating to buy *Bronze Queen* and when it flowers find it to be *Clio*, or to get Mrs. Clark and wonder next spring where all the Mrs. Moon came from. My practical advice to purchasers when ordering "new names"—that is, names which they have not come across before—is to be wary—very wary. Many are all right, but some are not.

Too-Much-Alike Varieties.—I really do not know into how many hundreds Darwins might not run if a complete list were to be made. In some the differences are so trifling that for practical garden purposes they are the same. I have, for example, this year, *Night*, *Faust* and *Ravenswing*, three exceptionally fine tall, dark varieties, but any one is virtually a replica of the other two, and the three are not wanted. *Edmée*, *Baron de la Tonnaye* and *Calliope*, as it was sent to me, are three more of which one might well say, when we see them blooming together, "How happy could I be with

any one, were the other fair charmers away." Moral: Now that Tulips are becoming more sought after, has not the time come for the Royal Horticultural Society to bracket too-much-alike varieties? Such a list would be very handy.

Some "Quite Nice" Tulips.—In taking notes one cannot help overhearing many remarks of bystanders. Their adjectival ejections are as finely graded as the explanatory word or words before "eggs" in a shop window. "Quite nice." I have come to the conclusion, is a grown-up and polite way of saying "jolly good." So here goes

THE CENTURY PLANT (*AGAVE ATROVIRENS*) ABOUT TO FLOWER AT KEW. VISITORS TO THE GARDENS DURING THE INTERNATIONAL EXHIBITION SHOULD MAKE A POINT OF SEEING IT.

biennial. The flowers, which are of a most beautiful orange scarlet colour, are borne in tiers on erect, slender stems about a foot in length. It makes a pretty and decorative plant when grown in a cool greenhouse, and, being quite hardy, does equally well in the open ground.

P. glutinosa is a bog plant, easy to grow, but almost impossible to flower here. I have grown it in quantity for years, and have rarely seen it in flower. I have compared notes with other growers, and find their experience similar to my own. This is a beautiful Primula and flowers freely in the Alps, where it is found.

for some "jolly good" Tulips which I have grown this year.

Short Darwins—that is, those which grow about twenty-two inches high. *Bleu Amiable* is a blue-purple of an elegant open Grecian vase shape with a very lovely interior, as the blue base is surrounded by a wide zone of rich purple, which gradually fades into lighter shades towards the top. Harry Veitch has appealed to a great many this year on account of its dark rich crimson coloring; it is a large flower, and as good for pots as for the open. William Pitt, my colour-chart tells me, is a deep shade of blood red with a brighter edging to the petals. I had never realised till this year what a remarkably good thing it is. *Suzon*, although a trifle taller than those mentioned, is a good-sized flower of a delightful shade of warm, pale pink, with a deep, almost salmony rose interior. It happens to be next to *Prince Maurity*, which is a plant about the same height and of a pleasing rich claret tone. The contrast is admirable.

Taller Darwins.—Mr. Farncombe Sanders reigns supreme in its own colour. I call it a vivid pinky rose, but other eyes see it a "vivid red" or a "dark crimson"; when the latter describer saw it he must have had blue spectacles on. "Fiery rose scarlet" is much better—possibly, even a better description than my own. *Viola* would assuredly be noted by all who love the dark claret shades. It has a big, well-shaped flower, something like *Giant*; but whereas there is a dulness in a bed of this latter, there is nothing of the kind in *Viola*. For those who prefer a blue-purple darkness, give me *Morans*. Kirke's plum with bloom on that will not wash off is how I always describe it to myself. It has a little of *Zulu* about it, but it does not look quite so much as if it was walking on stilts. *Rose Beauty*, which, strictly speaking, is a *Cottage*, happens to be alongside it. I am generally congratulated by visitors on my colour perception in placing the two together. As a matter of fact, it is pure hick that the two are growing where they are, but, nevertheless, the result is a very happy and striking one. *Rose Beauty* is a Darwin in all but name, of a real bright, clean rose, somewhat after *Cassandra* and some of the choicest of Mr. A. D. Hall's pure-based seedlings, of which I happen to be the fortunate possessor. *Mauve Clair* belongs to the mauve and lavender group, of which *Erguste* and Rev. H. Ewbank are well-known examples. But it is much taller and larger, and has a very distinct pale lavender edge to its petals. Just at first it is not as attractive as it might be; but give it time, and then you get a beautiful flower. *Michelin*, to which I am indebted

to my friend, Mr. Leak, for an introduction, has a large fine bloom of a pleasing shade of old rose, with a paler shade at the edge of the petals. It makes a very bright spot of refined colouring, and it is one of my new ones, of which I hope to get more this autumn. But I am running on regardless of the Editor and my paper. So many varieties are competing for the honour of being the tall stop that I have, metaphorically speaking, put them all in a bag, and out has come *Prince of the Netherlands*. Yes! it is well named. It looks a *Prince* among its compeers, *Edmée*, *Mrs. Krelage*, *La Fiancée*, *Baron de la Tomnaye* and the whole company of edged roses and pinks. It is tall and majestic, and there is a warm, soft tone in its rosy pink that, I cannot, at the moment,

THE ROYAL HOSPITAL, CHELSEA.

ITS HISTORY AND TRADITIONS.

THE soldiers' hospital at Chelsea, in the grounds of which the Royal International Horticultural Exhibition is being held, is one of the most precious of our public buildings. Although it is not so great and splendid as the sailors' hospital at Greenwich, yet it is a most perfect and singularly little-altered example of a civil building designed by Sir Christopher Wren, and executed without modification or delay under his direct supervision. The story of its origin, its founding, its erection and its organisation

is among the most interesting pages of our domestic history. As early as the reign of Elizabeth, the principle that the State should look after disabled soldiers was recognised, but very little was done practically in the matter until after the Restoration in 1660. The following year Sir Stephen Fox became Paymaster of the Forces and actively urged the cause of the maimed members of the Army. It was not, however, till long after he had ceased to be Paymaster that he succeeded in getting his scheme adopted. This scheme took the form of obtaining land and erecting buildings for the housing of Army pensioners.

The first question was the site, and it was considered that Chelsea, then a country village conveniently near London, would be in every way suitable. Charles II., on regaining the throne, had found an abandoned college and twenty-seven acres there in possession of the Crown, and had given them to the newly-formed Royal Society, of which John Evelyn and Sir Christopher Wren were original and active members. The Society found no use for the land and were ready to part with it at a reasonable price. We therefore find in Evelyn's Diary, under the year 1687, the following

entry: "Sept 14th, Din'd with Sr Stephen Fox, who proposed to me ye purchasing of Chelsey Colledge, which his Ma^y had some time since given to our Society, and would now purchase it againe to build an hospital or infirmary for souldiers there, in which he desired my assistance as one of the Council of the R. Society." The transaction took place, and additional contiguous land was soon afterwards added, mostly purchased from Lord Cheney, who was the principal Chelsea landowner, and whose name has been retained in more than one of Chelsea's thoroughfares. Two months after the meeting of Evelyn and Sir Stephen Fox, Letters Patent were issued under the Great Seal, declaring the Royal intention of creating a hospital for the relief of such land

VIEW IN THE HALL AT CHELSEA HOSPITAL.

associate with anything close. Everyone puts it down; but, alas! it is still a little expensive for ordinary mortals to order by the hundred. Some day soon, as it is a grand doer, everyone will have it in their garden. JOSEPH JACOB.

HABERLEA RHODOPENSIS.

Grows on the shady side of a rock garden, packed between stones in a vertical position, such as the *Ramendias* require, this interesting *Gesnerad* will render a good account of itself. It is a native of Eastern Europe, and in the near vicinity of the Shipka Pass in the Balkans, it grows freely and flowers in wonderful profusion throughout June. It is naturally a cool and shady loving plant.

soldiers as were or might be lame or infirm in the service of the Crown, and endow it with a suitable revenue. In the following February the first stone was laid by the King. Previously to that, Sir Stephen, who is described by Evelyn as having "the whole management of this," had asked the diarist "to assist him, and consult what method to cast it in, as to the Government." They worked together in Sir Stephen's study, and framed a scheme of the necessary officials and household, their duties and emoluments, and also regulations for the conduct of the institution, "which was to be in every respect as strict as in any religious convent."

Sir Christopher Wren had accepted the post of architect, and had produced the plans. In May he went in company with Sir Stephen and Evelyn with his "plot and design" to Lambeth to obtain the Archbishop's approbation of them. Until the land was needed it was let out as a farm to Thomas Franklyn, to whom thirty pounds was paid "in full satisfaction for damage by him sustained in his crop of turnips, in that part of his ground that was laid to the hospital in the years 1682 and 1683." Such is the story of the beginnings of the hospital as history paints it.

Soon after the building began, the Earl of Ranelagh became Paymaster, and his name is connected not only with the building and completion of the hospital, but with the history of that part of Chelsea. He was much in favour with William III., who granted him, in accordance with the rash and improper mode in which that

Sovereign squandered the Royal domains until Parliament restrained him, the whole of the eastern portion of the land that had been acquired for the hospital. On this land the Earl built a residence, and it would appear that he employed on its erection and decoration some of the same craftsmen he had under him at the hospital. They were men much employed by Wren. Maurice Emmett was the chief bricklayer here, as he was at Whitehall and at Hampton Court. Thomas Wise and Thomas Hill are master-masons at Chelsea as they are at St. Paul's Cathedral. At both these buildings we also find Charles Hopson, Roger Davis and John Smallwell as master-joiners.

The external materials of the hospital are a purple-brown brick for the walling and a rubbed red brick for the window openings. The coigns and the pedimented centres of the chief elevations are of stone, while the thick green slates of the hipped roof rest on an ample cornice. Internally it is the fine treatment of the woodwork that arrests attention. The staircases are very plain,

but are splendid in their amplitude and the easy swing of the ascent. This is greatly to the convenience of the aged and infirmed pensioners lodged in sixteen great wards or galleries, each occupying on different floors half the length of one of the sides of the building, which forms three courts. Oak is the wood universally used, and there can be no doubt that the whole of the joinery was designed by Wren himself. It is simple and reserved, and very practically adapted to serve the purpose in view. But it is all so good in line and proportion as to be most effective and satisfying in appearance. A row of windows occupies one side of these galleries, and on the opposite side, broken only by a great central fireplace, is a set of cubicles. They are partitioned off in Oak wrought in the large dignified panels and the rich and ample cornice mouldings of the period. Each one has, next to its little doorway, a big hinged panel which enables the pensioner

and reading room. The decorative scheme is dignified but simple. High wainscoting of Oak lines the walls. Above this, across the entrance end, runs an Oak gallery supported on carved consoles and with enriched mouldings to its panels. In the centre is a carved cartouche containing the Royal arms and surrounded with Palm branches. The west, or high table end, is principally occupied by a great fresco painted by Verrio, which, according to the inscription upon it, was given by Lord Ranelagh, although in the hospital accounts there appears the item £210 15s. paid to the artist "on account of painting in ye hall." The subject is Charles II. in the same classic dress which he wears in his statue by Grinling Gibbons in the centre of the court, while behind him is seen a presentment of the hospital buildings. The painted area is carried on for some distance along the side walls, where it represents trophies of arms, and the whole is bordered by a representation of a carved and gilt frame. Below it the wainscoting has a moulding beautifully wrought with wreathed Oak leaves intermixed with flowers. That is the utmost elaboration that the woodwork of the hall reaches; but in the chapel we find carving of great richness and excellence.

What was then called the "council chamber" is now known as the Governor's State Drawing Room. It is a large and beautifully-fitted apartment occupying the south-eastern corner of the centre court on the ground floor. James II., during whose reign the

CHELSEA HOSPITAL FROM THE EXHIBITION GROUNDS.

to enjoy privacy if it is closed, or to look out on the life and general activity of the ward if he opens it. Here is the account of one of the joiners for his share of the work in these wards and in adjacent premises:

"Charles Hopson, joyner, his taske worke wainscoting the second & third galleries in the west wing, viz, xiiijth, and for pieces of wainscoting in the great staircase and kitchen pavillion, the great staircase by the pavillion next the Thames, in the west wing, and in the hall, vs, lxijth xijs iijd ob."

Most of this, though fine, is plain joiner's work only; but more ornamental treatment begins with the hall which Hobson wainscoted. In the middle of the north elevation of the centre court and enclosed under a lofty portico lies a great square vestibule, and right and left of it open out the chapel and the hall, each of which is 108 feet long and 37 feet wide. The pensioners now mess in their wards, and the hall is their play

Council Chamber, where his initials, as well as so many other parts of the hospital, were fitted, appears to have taken a very direct and personal interest in the work and urged it on in order that it might be occupied by the intended pensioners. He, therefore, gave many verbal orders to Lord Ranelagh, who had to explain the position fully in a minute to the Lords of the Treasury when he presented his accounts in the following reign. He would not, however, find any difficulty in obtaining payment, for he was much favoured by William III. After his death his house and gardens passed into hands that laid them out for public use, and they became the famous Ranelagh Gardens of the eighteenth century. William III.'s foolish and imprudent gift has needed, in more recent days, the outlay of a large sum in order that the hospital might regain the portion of the ground that it had lost. By a happy chance it has come down to our days almost free from what the flux of fashion labels and re-labels "improvements."

REVIEW OF THE ROYAL INTERNATIONAL SHOW.

IN sunny weather the long-looked-for Royal International Horticultural Exhibition was opened by Their Majesties the King and Queen at twelve noon on Wednesday last. It is safe to say that the ancient craft of gardening has never before attracted so large and brilliant an assembly. Not only were Ambassadors representing all the important nations there, but statesmen, men of letters, and every form of distinction were present. Their Majesties were received by His Grace the Duke of Portland, who is president of the exhibition, and, after shaking hands with the Ambassadors and some of the directors of the exhibition, made an extensive tour of the tents and grounds and expressed themselves as being very pleased with all they saw.

Taken as a whole, the exhibition is quite up to expectations. Such a display of rare and lovely flowers, rock gardens and plants has never been witnessed in this country before, if, indeed, anywhere in the world.

The large tent alone is a sight not easily to be forgotten. Roses, Rhododendrons, magnificent banks of Ferns, fruit trees, greenhouse and stove plants of various kinds, as well as new Chinese plants, are represented on a luxurious scale. The Orchid Tent, too, is a feast of colour, and it would be difficult for anyone to estimate the value of the thousands of beautiful plants that are staged in it. Fruits and vegetables, though not shown on a very extensive scale, are exceptionally good, and it will be a source of gratification to all connected with the show, or indeed gardening of any description, to know that His Majesty the King has secured two first prizes for fruit.

The rock and other gardens are an exhibition in themselves; for design and workmanship, as well as good taste, the majority are excellent, and it is an educational feature that we think these will be most appreciated.

The characteristic that strikes us more forcibly than any other at the moment of going to press is the high quality of all the plants, flowers, fruits and vegetables that go to make up this wonderful show. It is a marvellous tribute to the skill of gardeners in this and other countries, and will, we hope, be the means of drawing attention to a class of men who in the past have not had their due share of recognition from the general public.

In the pages that follow will be found a review of the best exhibits in the show. Owing to the fact that this issue had to go to press immediately after the opening of the show, it is not possible to give the names of prize-winners, except in a few instances, but these are all being published

in a handy book by the directors of the exhibition. Next week we hope to give descriptions of the new plants that have gained awards, as well as a review of the horticultural sundries.

THE ROCK GARDEN.

To say that there are rock gardens by the acre, that there are hundreds of tons of rock representative of many diverse types geologically from various parts of the country, associated with hundreds of thousands of alpine and other hardy plants gathered together, would

all our readers as something to see, and certainly worthy of study and emulation. Hitherto Messrs. Wallace have given proof of their masterly grasp and finished work in this field, but never before have they attempted anything on such a magnificent scale as this or accomplished a work that has placed a crown on the head of all previous efforts. It comprises some eight thousand square feet of a rather crudely shaped valley between trees. And out of this have been fashioned rock and water gardens, an Old English terrace garden, brightly furnished borders, wood hut and Lily plantations, with waterfall and the like. The conception of the idea is as great as the work is finished and complete and natural—as natural, indeed, as the

THEIR MAJESTIES THE KING AND QUEEN INSPECTING THE FLOWERS AT THE EXHIBITION.

convey to our readers but the vaguest idea of the magnitude of a work which for weeks past has engaged the attention of all who garden chiefly in the open air.

In some instances, notably that of Messrs. Wallace and Co., Colchester, a great work has been achieved, the magnitude of which can only be gauged by the time the work has been in hand and the numbers engaged. For a month or more some twenty or thirty men have been busy excavating, moulding, shaping and building up this splendidly-conceived rock and water and terrace garden, with the result that we have presented to us such work in the exhibition field in a perfect manner and on a really magnificent scale. In the open it is one of the greatest features of the whole exhibition, one to which we would direct

combining of so much in such an area renders possible. It is, indeed, a praiseworthy and successful attempt of adapting the work to circumstances and surroundings, and no effort has been spared to accomplish the end in view. At the entrance the visitor is first led by way of an easy grassy slope to the water's edge, and anon by rather spacious, well-conceived pathways to other parts. Presently, by way of steps, the terrace garden is reached, and from this the border and the woodland beyond. The work of excavating and forming the whole has involved the moving of a great mass of earth, height and depth and varying aspects having been gained thereby. The rock chiefly used is Purbeck limestone of oolitic character, beautifully stratified and in every way eminently suited to the work.

The mass and variety of plants employed is enormous, and it is quite impossible to enter into details concerning them. Everywhere are groups and colonies of plants deftly planted and set out with discretion and skill—now a mass of *Primula*, *Trollius*, or *Epimedium* near the water's edge; fine groups of *Orchis foliosa* or *Yuccas*; delightful batches of hardy Ferns adorning the sides of the cave and, not less beautiful, the Iris border, where many delightful varieties are to be seen in bloom. This fine piece of work is non-competitive, and without hesitation we pronounce it the noblest or its kind that has ever appeared at an exhibition.

by our readers, and will not be missed, indeed, by any lover of alpine plants. *Iris cristata*, exceptionally well grown, is also charming in this group, and so, too, are *Oxalis enneaphylla* and *Ramondias*.

Messrs. Whitelegg and Page, Chislehurst, have arranged a pretty rockery bank with water pool, and associated therewith a number of suitable plants. *Cheiranthus Allionii* and *Saxifraga aizoon rosea* are of much merit, while of border plants nothing stands out so prominently or well as the new *Geum Mrs. J. Bradshaw*. Very good, too, are the alpine *Columbines* in the group, which cannot well escape notice.

below. The sides and banks are for the most part deftly planted—possibly a little over-planted and over-coloured here and there—while the crevice planting is certainly good and usefully suggestive to those contemplating similar work. The variety of plants employed is very great, some of the finer being *P. hulleyana*, *P. cockburniana*, *Cobweb Houseleeks*, *Fabiana imbricata*, *Edelweiss* and *Saxifraga Cotyledon*. A superb colony of *Cypripedium spectabile* is not likely to escape the notice of anyone interested in hardy flowers.

In near proximity is an effective rockwork arrangement from the Guildford Hardy Plant Nursery, and here the visitor will quickly get into touch with so good a plant as *Polygonum sphaerostachyum hybridum*, with its rosy-coloured spires; with *Celmisia spectabilis*, or the delightful miniature shrub *Enonymus microphylla argentea*. *Anthyllis montana*, the semi-shrubby *Lithospermum graminifolium* and *intermedium*, *Primulas bulleyana* and *Unique* and the rare *Swertia perennis* are all things to be looked for in this excellent group.

In due course the Rambler amid rock garden scenes will come upon a splendid arrangement by Mr. Maurice Prichard, Christchurch, Hants, who, while embracing an area of some three thousand or more feet, has achieved a splendid success with a rock and water garden and moraine, the latter of which alone is capable of fixing the lover of alpine vegetation for an hour or more. It is most likely to be in the latter range, should the visitor get into touch with the owner, for Mr. Prichard is nothing if not enthusiastic, singularly genial, and ever willing to impart information about the plants he loves so well. And the hosts of them, their beauty and variety and the consummate skill in placing and arranging them, goes far to tell of the enthusiasm of the man and his knowledge of the work. Among the gems in the group, the visitor must not overlook *Helichrysum frigidum*, *Omphalodes Luciliae*, *Oxytropis uralensis*, *Silene Hookeri*, *Sedum pilosum*, *Arenaria verna fl.-pl.*, *Thalictrum pubescens*, *Edraianthus pumillorum* and *Oenothera ovata*. *Saxifragas* are there, too, in plenty, the lovely *Dr. Ramsay* an aristocrat among them. The arrangement is that of rock and water garden combined, and is non-competitive. The rock is the Purbeck oolitic limestone, selected with care and arranged with skill. Bold masses of *Funkias*, *Iris*s and *Trollius* occupy congenial spots, and, generally, those hungering and thirsting after knowledge will find much that is useful and suggestive in this excellent piece of work.

Messrs. William Cutbush and Son, Highgate, N., occupy a position not far away, and, covering an area of about three thousand feet, have got together a rock and water garden of delightful aspect, richly endowed and furnished with suitable plant-life. This group is singularly rich in bulbous plants, and *Lilies* more particularly, and of these alone in their great variety and beauty Messrs. Cutbush have provided a great feast to which every reader of these lines is cordially invited. Such species as *Grayii*, *Brownii*, *Humboldtii* magnificent, the lovely golden-flowered *Parryii*, *Kelloggii*, *Martagon album* and the stately *giganteum* are all there, not in feeble array, but in great representative abundance. A great colony of *Cypripedium spectabile* is a feature; the unique *Ostrowskia magnifica* is there, too; and so, also, are the rare *Meconopsis sinuata* and the pale yellow *M. integrifolia*. *Armeria laucheanae* contributes a fine bit of colour, while shrub, alpine and aquatic in variety

MESSRS. R. WALLACE AND CO.'S ROCK AND WATER GARDEN.
THIS WON THE CUP OFFERED BY QUEEN ALEXANDRA FOR THE BEST ROCK GARDEN.

In another direction Messrs. Backhouse and Son, York, have a particularly good piece of rockwork, one of 600 feet in the competitive section and another of some three thousand feet or four thousand feet non-competitive, the latter combining water as well. In this also there is seen some excellent work, the whole being richly clothed and furnished with rare and good plants. Here the visitor may find great colonies of delightfully-grown *Ramondias*, *Pinguicula grandiflora*, *Anemone sulphurea*, *Oxalis enneaphylla*, *Viola pedata*, *Primula sikkimensis*, *P. cockburniana* and *P. japonica*, *Celmisias*, *Saxifraga longifolia*, *Orchis foliosa* (a superb lot), *Viola gracilis* and the rarely-seen *Ranunculus Lyallii*, with its handsome flowers of glistening white above a setting of glossy peltate leaves. This is perhaps one of the rarest plants in the exhibition, one to look for and admire.

Messrs. Jackman and Son, Woking, have a rockwork display of a non-competing kind extending to about one thousand feet, handsomely and freely furnished with many choice things. The splendid specimen examples of the ever rare and beautiful *Acantholimon venustum* are a great treat, magnificent tufts the like of which we have not seen before. This is a subject not to be missed

Mr. J. Wood, Boston Spa, Yorks, has a fine exhibit in the competitive section, the well-weathered York limestone in good stratified examples attracting attention at once. Among interesting and good plants to be looked for are *Iris Lacustris*, *I. cristata*, *Cathcartia villosa* (rich golden Poppy-like flowers with hairy leafage), *Trilliums*, *Saxifraga paradoxa*, *Aquilegia glandulosa*, *Edraianthi* and many others. *Primula sikkimensis* and *Cypripediums* are also above the average. This group is fronted by a serpentine streamlet, and is nicely arranged.

Near by, Messrs. Barr and Sons, Covent Garden, have a similarly-sized rock garden group and rock wall, the rock of the former being also of York limestone. There is a remarkable variety of plants here, and the casual observer will not be likely to miss the Ferns, *Cypripediums* and *Saxifragas*, any more than the specialist will overlook the fine examples of *Onosma Bungei*, *Anemone sulphurea*, *Primula cockburniana*, *Sarracenas*, *Iris*s, or other good plants.

Messrs. Piper, Bayswater, have a most distinctive rock garden exhibit in the 600-foot competitive section, the chief feature of which is a huge cave with water overtopping in a pool and streamlet

give their quota of interest and value to a very excellent whole.

Messrs. J. Carter and Co. have a large and comprehensive Japanese garden. On entering the garden we pass under a thatched archway, flanked by two beautiful old bronze Japanese lanterns. This entrance alone is a feature of great interest, but it is simply a part of the whole scheme and merges into the picture. Passing on, towering above the grouped flowers is a very fine old stone lantern, aged 450 years, one of those quaint and exceedingly beautiful examples of the art of the Far East. Near by is another beautiful ornament in bronze. This represents the sacred Hoho bird of Japan, with its seven tails. To the right is a Japanese well, with the pulley beneath a quaint thatched roof, and close by is a very fine Japanese monument, over five hundred years old. At the far end the lake is spanned by a light and graceful Japanese bridge with a house in the centre. But the *pièce de résistance* is a very fine bronze eagle on a rugged stump, standing about eight feet high, specially procured from Japan at a considerable cost. The whole garden is furnished with very old and quaint stone lanterns, and as the exhibition is open until ten o'clock at night, the scheme of illumination is of plain green Japanese lanterns, which give a very charming effect.

Mr. H. Hemsley, Crawley, who entered the 600-foot rock garden competition, has a very pleasing group in rock composed of Sussex sandstone, planting it freely and well with alpiners and shrubs. *Sutherlandia frutescens*, *Onosma taurica*, *Shortias*, *Pentstemon glabra rosea*, *Cathcartia villosa*, *Edelweiss*, *Saxifrage*, with *Onosma stellulata*, are among important plants to be searched for in this interesting group. Adjoining there is a tiled garden of formal outline that is bound to catch the eye.

Baker's, Wolverhampton, have a rock and water garden arranged on a superficial area of 2,000 feet, planted in a most effective and attractive way. Quite a variety of useful plants are employed, though we would especially direct the attention of our readers to such individual subjects as *Cathcartia villosa*, *Achillea Kellereri*, *Oxalis enneaphylla*, *Campanula Allionii*, *Asperula suberosa*, *Dianthus subacaulis* and *D. arvensis*. The water garden portion is particularly well done, and, associated with moisture-loving *Primulas* and other suitable plants, constitutes a most agreeable whole.

Messrs. Ware, Limited, Feltham, have arranged a spacious rock and water garden on an elaborate scale, some six thousand feet being covered by this exhibit alone. Wall, rock and water gardening all enter into a scheme which is admirably conceived and well carried out. We can only regret that space will not permit us to enter into descriptive details.

Messrs. J. Cheal and Sons, Crawley, have an admirably-conceived pergola, rock and water and terrace garden all in one, or, rather, a continuance the one of the other. In conjunction with this the old Tudor garden and Lily pond are in delightful harmony, the rock garden, executed in Sussex sandstone, being among the things to search for and admire. The whole scheme is carried through on a most elaborate principle, the rock garden and pergola work being well worthy of a visit and close study.

Mr. H. C. Pulham, Elsenham, Essex, has a most elaborately-designed rock and water garden, covering a superficial area of some four thousand five hundred feet. Red Norfolk sandstone, at once good in colour and sympathetic to plant-life,

is that employed, and with a series of cascades and waterfalls a most effective whole is the result. In this way there is a difference of 15 feet or 20 feet between the upper and lower levels, shrub and plant of taller growth occurring in the former, with alpine, aquatic Fern-life and the dwarfest of vegetation occurring low down or at the water's edge. Many tons of stone appear in this exhibit alone.

Mr. Amos Perry, Enfield, has arranged between tents many good hardy plants, aquatics and Ferns in groups.

Mr. G. Reuthe, Keston, has a most interesting lot of things; and there are a score of others who have set up alpine and rock or allied exhibits with taste, forethought and skill, to which we have no space to refer in detail.

ROSES.

One has become so accustomed to viewing superb displays of our national flower at the Temple Show that no one could be surprised to find growers surpassing all previous efforts. Instead of the restricted space which made the grouping at the Temple somewhat cramped, there is here plenty

Although these notes are written before the awards are made, we should say the jury will have great difficulty in passing over the superb group of Messrs. Paul and Son of Cheshunt, a group worthy of the great firm that has so often carried off the gold medal, and which may be fortunate enough to secure the coveted cup of the Worshipful Company of Gardeners on this occasion. Weeping standards are here in all their beauty, from the gorgeous *Excelsa* to the dainty *Lady Godiva*. These Roses are worked upon a special stock, which, at least for pot culture, have the great merit of lightness of stem and elegance throughout. Among the splendid and well-flowered weepers we noticed one consisting of a quartet of beautiful sorts, namely, *Excelsa*, *Lady Godiva*, *Dorothy Perkins* and its white sport—a happy blending of colour and of kinds that bloom simultaneously.

We cannot in our limited space give the names of the great variety to be seen in this group, but will content ourselves with naming a few. Perhaps the best novelty is one of Messrs. Paul and Son's own raising, named *Freda*. It is a really superb Rose, "a pink *Bessie Brown*," as Mr. Paul termed it; but really we think this does not do it justice, because it appears to us to be of even more

SOME OF THE JAPANESE LANTERNS AND STORKS IN MESSRS. J. CARTER AND CO.'S JAPANESE GARDEN.

of scope that has given the floral artist all that he could desire. One's mind goes back to the shows of years ago, when there were no ramblers and no *Polyanthas*, and the groups then, although composed of a few huge specimens, were so totally different from those on view now as to really startle one by the great advance made in the culture of Roses in pots, and the large place taken by ramblers and *Polyanthas* as decorative plants. Not only do we find them in the large groups composed entirely of Roses, but they are also employed in groups of miscellaneous subjects, as well as to decorate the pavilions about the grounds.

elongated form than that well-known variety. A superbly-coloured *Juliet* is growing in standard form, and portrays the suitability of this unique Rose as a standard. *Nelly Johnstone*, *Mrs. A. R. Waddell*, *Arthur R. Goodwin*, *Lady Pirrie*, *Marquise de Sinety*, and *Queen of Spain* are magnificent, and the lovely little white *Polyantha Jeanne d'Arc*, the deep pink *Maman Levavasseur*, the brilliant *Jessie* and others complete the *tout ensemble* of this choice display.

Messrs. W. Paul and Son of Waltham Cross have also a noble group, the individual specimen ramblers being grand both in colour of blossom and quantity,

and they have been timed to a day. Paradise is really very fine, the quaint blossoms showing up like so many gorgeous stars. Elsie is a lovely flesh shaded sort, with very beautifully-formed blossoms, and American Pillar is so well flowered that no one can doubt its usefulness in the garden. A mass of the dainty blush pink Edward VII. is here shown, and a most charming Polyantha it is, perhaps one of the loveliest of all; and although sometimes the colours of this class alter when grown outdoors, we are assured this variety is even more beautiful in the open. Among the exhibition and garden varieties, Portia is well to the front, and the beautiful golden yellow of Lady Doune, its flowers borne upon erect stems, shows what a fine bedder it will be. Frances Charteris Seton is a novelty of decided merit and deliciously sweet; its cherry red colour and shapely blossom will commend it to all who love exhibition Roses.

Masses of Polyantha Roses go to the making up very largely of Messrs. Cutbush and Sons' group, and it is very fitting that this firm, who practically introduced Mrs. W. H. Cutbush, should be well

Society's shows, but to-day he is surpassing himself, not so much with the huge show bloom sorts as with grand masses of ramblers, forming perfect pyramids of bloom. The plants are particularly well flowered, and Mr. Mount has made good use of dwarf plants of Crimson Rambler as an edging, showing that this old Rose may be effectively used as a bush plant. A small group of highly-coloured Juliets are a marvel of colouring, and we are pleased to find that Mr. Mount has placed this Rose well away from reds, a colour that should never be placed near this unique variety.

Messrs. Hobbies and Co. of Dereham are making a very big effort towards showing what a Rose garden should be. They have, unfortunately, many plants that will be better in another week, so that visitors next week will see better the beauty of this group than those who visit the show on the opening day.

To the introducer of Crimson Rambler we naturally look for some good novelties, and Mr. Charles Turner has not disappointed us. The fine group from Slough has among its many

of the foregoing groups are to be found in the large tent, and go far to make this wonderful tent the great triumph it undoubtedly is. We should say no more splendid array of Flora's wonders has ever been brought together under one canvas.

In the same huge tent most of the minor classes for Roses are to be found. At one end are groups of pot Roses and cut Roses combined, and here we find some fine quality. Messrs. Frank Cant and Co. are very strong in this section, having really grand flowers of Gustav Grünerwald, Lady Mary Corry, Mrs. H. Stevens (a beautiful white Rose that will become a favourite) and also the marvellously-coloured Marquise de Sinety. We also noted a fine plant of the new Climbing Souvenir de Pierre Notting, which will be very welcome as a wall climber on account of its beautiful Maréchal Niel like blooms.

Messrs. W. and J. Brown of Stamford are displaying some nice bushy plants of Mrs. Flight, which show what may be done with ramblers as dwarf rather than as columnar plants. This group also comprises many choice things in cut form, the whole overshadowed by a large Laburnum growing in the grounds, whose golden panicles droop gracefully over the Roses, supplying a shade of colour that enhances their beauty.

Mr. George Prince of Oxford brings many lovely specimens of the Tea Roses he so well knows how to grow, and Mr. Hugh Dickson of Belfast puts up a group of pot plants of some of his lovely novelties, such as Mrs. C. Allan, Countess of Shaftesbury and the delightful Lady Pirrie, a Rose quite unique in its colouring, and one most adaptable for culture under glass. Mrs. C. Allan is not seen at its best here, for outdoors the colour is of that wonderful hue seen in Mme. Hector Leuilliot, with just a shading of pink. This is a Rose to make a note of, and is perhaps one of Mr. Dickson's best introductions for the garden.

Standard Roses in pots are grandly shown by Mr. Charles Turner, the trees the picture of health. These trees were potted up in the autumn of 1910, grown outdoors last year, the pots being sunk into the ground, and then brought indoors this spring. They were only top-dressed with good loam and Thomson's Manure. Amateurs should see these standards, as it is evidence of what may be done with standards as plants for conservatory decoration.

Messrs. Paul and Son have also some very finely-flowered standards.

Two competitors enter for the class for 100 plants of Polyantha Roses, namely, Messrs. Charles Turner and F. Cant and Co. In the first-named group the plants are elegantly arranged, and the sorts are the lovely white Katherina Zeimet, Aennchen Müller, Jessie, Mrs. Cutbush and Mme. N. Levavasseur.

In No. 2 Tent, Messrs. Prior and Son of Colchester have a very lovely group of choice things, and their cut blooms show they have lost none of the art as cultivators.

Messrs. Dicksons of Chester are using ramblers largely in their splendid group of miscellaneous plants in the large tent.

We fear the weather has been too much for amateurs, for up to the time of writing we could find only one group of pot plants. This one, however, is very excellent, and comes from James Brown, Esq., Heaton Mersey. It goes to show what we may expect when the spring show of the National Rose Society is an accomplished fact, a show which we may expect next year, according

THE OLD ENGLISH GARDEN EXHIBITED BY MESSRS. J. CHEAL AND SONS.

represented by these little pet Roses. Quite one of the prettiest Roses in the exhibition is the Baby Tausendschön, a variety, if we mistake not, that will be much sought after. Here it reminds us in colour of a very old Rose, Mme. Pierre Oger, only, of course, very small; but the flowers are prettily cupped and are produced in great profusion. Dwarf standard Polyantas on the rugosa stock are elegantly dotted about in this lovely group, and one cannot but hope they will be more frequently planted in this form, especially as centre-pieces to beds of the same Rose or contrasting colours. The very brilliant Jessie is a variety that will soon largely displace the scarlet Geranium, for last year, when these plants were looking very sad, beds of this little Rose were as brilliant as one could wish. Masses of pillar Roses of such sorts as Mrs. Flight break up the group, and the whole forms a most superb spectacle.

Mr. George Mount is never so happy as when making bold displays. We have had some lovely groups from him this year at the Royal Horticultural

attractions two Roses that we venture to prophesy will be in every garden very shortly. One is named Ethel, a most dainty rambler of the Dorothy Perkins type. It is so light and graceful in its clusters, and it has the merit of flowering some days earlier than Dorothy Perkins, a great gain, as all who love these Roses will admit. The other novelty is named Coronation. Out of doors its colour is much brighter than Excelsa; although so brilliant when grown under glass, the colour of Excelsa outdoors is somewhat dull. Coronation is of the Hiawatha type of growth; its flowers are large, fairly double, but showing a clear white centre with a wealth of golden stamens. This variety, too, is earlier than Hiawatha.

Polyantas and ramblers are splendidly shown by Messrs. S. Low and Co., and one of the loveliest is Eileen Low, a Rose with the airy lightness of Jessie, but of a nice soft pink tint. This beautiful novelty originated with Messrs. N. Levavasseur and Sons of Orleans, a firm to which we are indebted for so many of these pretty Roses. All

STOVE & GREENHOUSE PLANTS.

The most extensive exhibits of these plants are arranged in the huge tent in which are grouped a great variety of different subjects, hardy as well as tender.

Messrs. Sutton and Sons of Reading are, as usual, well to the fore, their exhibit, which is disposed around the well-known obelisk erected to the memory of those who fell in the Battle of Chillianwallah, being arranged in their well-known and most effective style. A notable feature of this exhibit is that the entire collection has been raised from seed. Particularly noticeable among the different subjects contributing to this wealth of blossom are Schizanthuses of different kinds, which have of late years become so popular; various sections of Cinerarias, including the comparatively new Reading Gem, and Calceolarias, of which Sutton's strain is renowned all the world over. *Primula obconica*, too, shows well

the vast improvements that have of late years been effected in this species, not only in the size and shape of the flower, but also in the colour thereof. Gloxinias, which are numerous represented, include among their number the crimson-scarlet King George V. and Her Majesty, with pure white blossoms. From lack of space we can only mention the Begonias, Clarkias, Nemesias, Phlox and Nicotianas of different colours. The edging of fresh, rich green grass serves admirably as a foil to the bright-coloured flowers.

Messrs. James Cypher and Sons, Queen's Road Nursery, Cheltenham, have long been celebrated for their artistic groups of stove and greenhouse flowering plants, and in one of the competitive classes they put up a magnificent group, exceedingly light and elegant in effect. Another exhibit of

Messrs. Cypher's recalls bygone days, as it is made up of magnificent specimens of flowering plants. Some that cannot possibly be passed over are *Clerodendron Balfourii*, *Ixora Pilgrimii*, *Stephanotis floribunda*, *Statice intermedia*, *Polygala dalmaisiana*, *Erica Cavendishii*, *E. depressa*, *E. ventricosa* magnifica, *Azalea grandis*, *A. Model*, *Franciscea (Brunsfelsia) eximea*, *Ixora Williamsii* and *Bougainvillea Cypherii*, remarkable for the rich colour of its bracts compared with those of the better-known *Bougainvillea glabra*.

Messrs. E. Webb and Sons, Wordsley, Stourbridge, are showing many of the same kinds of flowering plants. The most conspicuous are arranged in semi-circular groups, and all and every one show evidence of high culture. Where all are so good it is difficult to single out any particular ones for praise, but the *Calceolarias*, *Schizanthus* and the *Cinerarias* of the *stellata* section are so fine that it is impossible to pass them over. Besides these different subjects, seedling *Hippeastrums* of a very superior strain are shown in quantity.

Near by, Messrs. Veitch are showing about one hundred and fifty of their noted strain of *Hippeastrums*. This strain has long been famous, and has many times gained high honours. The present exhibit is well calculated to maintain the high standard that Messrs. Veitch's *Hippeastrums* have now reached.

A startling exhibit of *Hippeastrums* is that set up by Messrs. R. P. Ker and Sons, Aigburth Nurseries, Liverpool. Ker's *Hippeastrums* are justly famous, not only for the high character of their blossoms, but also for the great variety that exists among them. While all are good, a few stand out in such a manner that their merits can on no account be passed over. Particularly striking are *International* (warm orange netted with red, with a white central band and a metallic violet suffusion in the centre of each segment), *Midnight* (deep blackish velvety crimson), *Salmon King* (rich salmon red), *Ophir* (yellowish buff, the nearest approach to a yellow flower, for which Messrs. Ker have been trying for some years), *Persephone* (flower of perfect shape, white, lined with red in the upper segments), *King George* (soft rose, light stripe at the basal half of each

ROSES SHOWN BY MESSRS. STUART LOW AND CO.

to the remarks which the president let fall at the conference on Monday last.

No visitor to the show should miss the beautiful display of novelties put up in the French Section by M. Pernet-Ducher. It is one of the choicest groups in the whole show, and contains some seedlings not yet in commerce, varieties that will cause quite a sensation. Here we may find the superb Mrs. George Beckwith, a Rose that may even surpass Rayon d'Or. Sunburst is in grand form, and it is shown in two groups, one of its true colour, and another portraying the blooms that come from the hard wood, which are quite pale. It is such a splendid Rose that we can overlook this little fault. Perhaps it may be well to remove the first blooms in the early stage, as then the second crop from the young wood are sure to come the deep golden colour we love so much. Mme. Heriot is likely to be quite a sensational Rose when seen as it will come outdoors. It has the lovely colouring of *Beauté de Lyon*, with the shapely buds of the Hybrid Teas, and the growth is quite erect. President Vignet, *Souvenir de Gustave Prat*, Mme. Charles Lutand, *Lyon Rose*, *Lieutenant Chaure*, *Viscountess Enfield*, *Rayon d'Or* and *Arthur R. Goodwin* provide a sumptuous feast of colour such as no raiser has ever given hitherto.

In the same tent Messrs. Turbat and Gouchault are showing some grand *Polyanthas* that have quite large flowers, one, a white *Yvonne Rahier*, being a real gem.

Messrs. A. Dickson and Sons of Newtownards are showing some choice novelties; but at the time of writing we are unable to locate them. No one should go away from the show without seeing them, for we have found this group one of immense interest.

A MAGNIFICENT COLLECTION OF ROSES SHOWN BY MR. G. MOUNT, AND AWARDED SIR JEREMIAH COLMAN'S CUP

segment), Magnificent (rich crimson, lighter towards the edge, the crimson being there disposed in a freckled manner) and Pink Pearl (rich cherry pink).

Some two hundred seedling Hippeastrums are also shown by Messrs. William Bull and Sons of Chelsea, who for some years have devoted a good deal of attention to this showy class of plants. The varieties are good and well varied, while the condition of the plants leaves nothing to be desired. Particular note may be made of Brilliant (rich scarlet self), Enchantress (delicate blush), King George V. (glowing scarlet), Doris (delicate pink), Sybil (salmon), Primrose Dame (light primrose) and Loveliness (delicate blush rose).

Messrs. James Veitch and Sons, Limited, King's Road, Chelsea, are freely represented in the large tent.

One group, consisting mainly of fine foliage stove plants, occupies a prominent position, and deservedly so, as it is made up of grand plants, beautifully arranged. Each individual plant will bear inspection from whatever standpoint it is viewed, and all are so disposed that the full extent of their beauty can be readily seen. Although no two persons see eye to eye in such matters, yet the most indifferent cannot fail to be struck with the high cultural skill shown in the huge specimens of Caladiums, Crotons, Anthuriums, Alocasias, Dieffenbachias, Dracænas, Marantas and others. This is but a tithe of the different subjects composing this remarkable group. A new *Dracæna* shown by Messrs. Veitch is *D. deremensis Bausei*, in which the white variegation is much clearer than in the variety *Warneckii*, which was given an award of merit last summer at Olympia.

Messrs. Stuart Low and Co. are showing a great variety of flowering and general decorative plants in the large tent. The Bottle Brush Flower (*Metrosideros floribunda*), or, as botanists now call it, *Callistemon salignus*, shows up brightly where associated with foliage subjects. Whether the plants are grown as bushes or standards, the brilliantly-coloured masses of flower are very telling, and are much admired. The variety *alba*, with white or creamy white flowers, is much less effective than the typical kind. Of flowering subjects shown by Messrs. Low

are the pretty, graceful *Aotus gracillima* (with yellow Pea-shaped blossoms), *Fabiana imbricata* (that Heath-like member of the Potato family), *Hydrangeas*, *Heaths* of different kinds, *Carpenteria californica* (which is rarely seen flowering so freely in small pots), *Boronia polygalifolia*, *B. heterophylla*, *Correa cardinalis*, *Asclepias curassavica* and a fine group of the pretty little salmon-tinted *Azalea balsaminæflora*. As an edging plant is employed the Canary Island *Lotus peliorhynchus*, with its hoary leaves and scarlet bird's-beak-like flowers.

From Aldenham House Gardens come a delightful lot of *Pelargoniums*, in which occur many old-time favourites, especially among the scented-leaved kinds. They are all either original species or hybrids

therefrom, and from their uncommon appearance they appeal to many. Altogether about eighty sorts are shown, all being good, bushy specimens in pots 7 inches or 8 inches in diameter.

The huge specimens of scented-leaved *Pelargoniums*, which are trained in various ways, principally in screen shape, from Gunnersbury House (Mr. Leopold de Rothschild) form a notable and uncommon feature.

From Messrs. Fisher, Son and Sibray, Limited, Royal Nurseries, Handsworth, Sheffield, comes a fine group of *Crotons*, several of which have been raised by the firm. Of these last may be specially noted *Duke of Portland* (a medium-sized leaf with a large yellow centre), *Mrs. J. Grace* (which may be described as a yellow *Flambeau*), *Heathii pendula* (a seedling from *Heathii*, in which the foliage is

and *Streptocarpi*, all of their well-known strains, the plants showing evidence of good cultivation.

Messrs. Godfrey and Sons, Exmouth, Devon, exhibit a collection of show and decorative *Pelargoniums*, including all the best varieties in their respective classes. Their exhibit also contains a particularly fine form of *Amarantus tricolor*, whose leaves are as brightly coloured as the showiest blossoms.

In No. 3 Tent, Messrs. Cheal and Son, Limited, Crawley, are showing a collection of Dahlias in pots, an unusual exhibit for this time of the year. The varieties include *Cactus*, *Pompon Cactus*, singles and some members of the pretty *Tom Thumb* class.

The Hon. John Ward, Chilton, Hungerford, has a fine exhibit of *Streptocarpi* in large plants and showing a great variety in colour.

Messrs. James Carter and Co., Raynes Park, have a magnificent exhibit arranged in their well-known style. From a central stretch of turf of the most vivid green spring several beds of single *Petunias*, one of which, *Queen of Roses*, is the finest variety of that colour we have ever seen. Other choice varieties are *Purple Prince*, *Crimson King* and *White Pearl*, whose distinctive features are indicated by their respective names. The rich rose-coloured *Stock Queen Elizabeth*, and *Cineraria Brilliant Prize*, with huge blossoms, which serve to show the great contrast in the size of the blooms of this section compared with the small graceful blooms of the *stellata* class, are also shown. Being enclosed within light lattice-work painted pale green, the harsh lines of the huge tent and its supports are partially hidden by this, and a pleasing effect is produced thereby.

Begonias in No. 2 Tent form a gorgeous display. Messrs. Thomas S. Ware, Limited, Feltham, have a glorious lot of double-flowered varieties, including the magnificent pink form, *Lady Cromer*, of which a coloured plate was given in THE GARDEN for January 20 of the present year. Other varieties with huge, finely-formed and exceedingly beautifully-coloured blossoms are *May Queen* (bright salmon), *George V.* (brilliant orange salmon), *Margaret Guillim* (light yellow), *Mary Pope* (white), *Captain Lafone* (soft pink), *Lady Ebury* (carmine rose), *King Edward VII.* (rich crimson) and *Mrs. Whitelaw* (vivid orange).

Messrs. Blackmore and Langdon, Twerton Hill Nursery, Bath, have a very fine collection made up of magnificent double and single flowers, as well as several varieties of a loose, drooping habit of growth, a character that eminently fits them for growing in suspended baskets. Particularly striking among the double kinds are *Mme. Tetrizzini* (orange salmon), *Irene Lambing* (vivid orange), *Mrs. Peter Blair* (white), *Miss Ethel Gill* (rose, a particularly upright flower), *Princess Victoria Louise* (pale salmon pink), *Mrs. W. L. Ainslie* (rich yellow), and *Violet Langdon* (pale pink, deep rose

A PATHWAY COVERED WITH ROSES IN MESSRS. HOBBIES' GROUP.

far more drooping than in the type), and *Victoria superba* (marked heavily with rich orange). Besides these are such well-known kinds as *Warrenii*, *volutus*, *Reidii* and *Lady Zetland*, which with some choice forms of *Cordyline australis* go to make up a very effective group.

The *Hippeastrums* from Sir George Holford, Westonbirt, Tetbury, make a gorgeous display, the range in colours being considerable. What is more, the Westonbirt *Hippeastrums* have long been famous for their vigour, so that specimens bearing two and three spikes of flower are in the majority.

Messrs. John Peed and Son, Roupell Park Nurseries, Streatham, show *Caladiums*, *Gloxinias*

edge). Two new varieties in this exhibit are Red Cactus and Rose Cactus. In these varieties the flowers are made up of a number of long petals, which give to a bloom very much the appearance of a Cactus Dahlia. These varieties are of a somewhat loose habit of growth, and in addition to their being good decorative plants, they are well adapted for growing in suspended baskets. Messrs. Blackmore and Langdon also make a speciality of flowers whose edges are remarkably fringed.

Messrs. Charles Turner and Sons, Royal Nurseries, Slough, show a varied assortment of greenhouse flowering plants, including specimen Azaleas, which, though well flowered, cannot, however, compare in size with the giants of old. Heliotropes, grown in various ways, and Pelargoniums of different sections also make a good display.

E. D. Preston, Esq., Kelsey Park Gardens, Beckenham, shows a large flowering specimen of *Phoenix Roebelini*.

Lord Northcliffe, Sutton Place, Guildford, exhibits a nicely-arranged group of decorative flowering plants, such as Calceolarias and Cinerarias of different sections.

Messrs. William Artindale and Son show, in Tent No. 2, a bank of finely-flowered examples of *Pæonia Moutan* (Tree Pæony), among the best being *Queen Elizabeth* (deep rose), *Jeanne d'Arc* (pink), and *Mme. de Bugny* (white, with violet centre).

Mr. West Neve, West Court, Bray-on-Thames, also shows a group of these showy Pæonies.

In the large tent Messrs. Robert Veitch and Son of Exeter show two remarkably handsome and most interesting Calceolarias. The first, known as *Calceolaria Veitchii*, is the result of a cross between the weak-growing *Calceolaria alba*, with white blossoms, and an albino seedling of *Golden Glory*. Strange to say, the new-comer is a far more vigorous grower than either of its parents, forming as it does quite a bushy specimen some 4 feet to 5 feet in height, and flowers in great profusion; the colour of the blooms is of a milk white tint. This remarkable Calceolaria has proved to be hardy at Exeter, and comes quite true from seed. The second variety, *The Bronze Age*, is of free bushy growth, and bears in great profusion rich bronzy crimson flowers.

Messrs. H. Cannell and Sons, The Home for Flowers, Swanley, Kent, are staging an extensive group at one end of the huge tent. Against a background of climbing Roses are disposed a great number of choice flowering plants, including Calceolarias, among others being the bright yellow *Calceolaria Clibranii*, *Marguerite Mrs. F. Sander*, *Hydrangea arborescens grandiflora*, choice Pelargoniums, including some members of the curious Cactus race, and a very promising double-flowered member of the Ivy-leaved section called *Vicar of Shirley*. The flowers of this are deep scarlet, with a dark blotch in the centre of each segment. The variety *Salmon Paul Crampel*, which has already become a favourite, is also well shown. The flowering Cannas are well worthy of the reputation Messrs. Cannell have so long enjoyed, and the bank of flowering examples forms quite a mass of colour. A few of the most striking are *D. H. Thorn* (crimson), *C. Haussmann* (amber), *Gladiator* (gold, spotted red), *Prefet Bargeton* (deep amber), *John Farquhar* (salmon pink), *Frau G. Siebert* (yellow, lined crimson), and *J. B. Van der Schoot* (one of the best spotted forms). A notable feature is furnished by quite an extensive group of *Phyllocactus German Empress*, a very pretty pink flower.

Mr. W. H. Page, Tangley Nurseries, Hampton, is showing a remarkably brilliant group of Zonal Pelargoniums, consisting mainly of his three varieties, which have aroused a good deal of attention of late, namely, that rich-coloured variety *His Majesty*, the paler-tinted *Fiscal Reformer* and *Winter Cheer*. Each variety is disposed in a large hemispherical mass, and the blaze of colour is a striking one.

Messrs. Philip Ladds, Swanley Junction, Kent, also exhibit a large group of the finest market varieties, including such comparatively new kinds as *Salmon Paul Crampel*, and the still newer pink-flowered *Ambrosia*.

Leopold Salomons, Esq., is showing, towards the central portion of the large tent, a highly decorative group, the central portion consisting of blue Hydrangeas surrounded by well-grown and varied forms of *Schizanthus*, with an edging of *Maidenhair Fern*, alternated with the pretty purplish blue-flowered *Torenia Fournierii*.

The Rev. A. T. Boscawen, Perranwell, Cornwall, has a small exhibit, but in the opinion of many it

early days the improvement is most striking. Cannas, too, of the large flowering race are also largely shown, while the Cinerarias are innumerable in their variety. In the raising of Cinerarias Messrs. Veitch do not follow any hard-and-fast line, but carry out experiments with different species, and thus obtain varied results. One of their latest is *Pompadour*, with striped florets, but it does not appeal to the general public as markedly as do some of the others. The Cactus race are much admired, while the possibility of a clear yellow Cineraria is suggested by the variety *flavescens*, a cross between *Senecio auriculatissimus* and *C. Feltham Beauty*. The brilliantly-coloured flowers of *Kalanchoë flammea* stand out in a very conspicuous manner, as also do those of the new *Kalanchoë Excelsior*, for which Messrs. Veitch obtained an award of merit two years ago. This list might be indefinitely extended, but one or two items must not be passed over. They are *Clianthus Dampieri*, with its richly-coloured blossoms; *Elæocarpus dentatus*, an Australian shrub with prettily fringed bell-shaped blossoms;

CALCEOLARIAS IN MESSRS. E. WEBB AND SONS' EXHIBIT OF GREENHOUSE FLOWERS.

is one of the most interesting features of the show. It consists of three marked forms of the *Manuka* of Australia and New Zealand *Leptospermum scoparium*, a fairly well-known twiggy bush with small white Myrtle-like flowers. The three varieties shown are *Chapmannii*, of an upright habit of growth with rosy red flowers; *Boscawenii*, a loose-growing plant with flowers larger than those of the type, and in colour white with a red centre, the buds being red. The third is *Leptospermum scoparium Nichollii*, whose flowers are of a rich ruby red, quite a startling colour to those acquainted only with the common kind. Hardy in the favoured parts of the country, these *Leptospermums* would form grand conservatory plants elsewhere.

Messrs. Veitch exhibit in Tent No. 3 a charming collection of representative flowering plants of the different classes for which they have long been famous. *Streptocarpuses*, or Cape Primroses, are shown in blocks or masses of nearly every imaginable colour, and to those who knew them in their

Exacum macranthum, whose rich purple flowers are always admired; and *Gloxinias* in choice variety. Some twenty-five *Fuchsias* present quite a unique spectacle, each plant having several shoots trained to the angle of the roof of a greenhouse, thus showing their value for clothing the rafters of such structures or for similar purposes. The varieties grown in this striking manner are *Clipper*, *Final*, *General Grenfell*, *Lustre*, *Mrs. Marshall*, *Mrs. Todman*, *Olympia* and *The Shah*.

Miss Troyte Bullock, North Coker House, Yeovil, Somerset, has in No. 2 Tent a delightful series of Pelargoniums, mainly scented-leaved forms. Many of them are true species, while others are old hybrids whose early history is in several cases now lost. As this collection is made up of 126 distinct forms, we should say that such a collection must be almost, if not quite, unique.

In No. 3 Tent, Messrs. William Artindale and Son of Sheffield show a large and varied collection of the very best forms of *Primula obconica*, whose blooms vary in colour from white to rich carmine

crimson. The pretty white-flowered *Abutilon Sawitzii* has a very nice effect arranged with these *Primulas*.

Messrs. Stuart Low and Co., Bush Hill Park, Enfield, have in the same tent a very striking series of the newer hybrid forms of *Gerbera*.

From the gardens of the Marquis of Salisbury, Hatfield, comes a pleasing group of the pretty little violet-coloured *Saintpaulia ionantha*, over which are arranged a few light Palms and plants of the graceful *Cyperus laxus*.

From Tresco Abbey comes one of the rarities of the show, namely, a flowering example of the Andean *Puya chilensis*. From a mass of thick Aloe-like leaves is pushed up a sturdy 6-foot spike, the upper portion of which consists of a crowded head of curious green flowers with yellow stamens. This *Puya* is perfectly hardy at Tresco.

Mr. Bruce, The Nurseries, Chorlton-cum-Hardy, Manchester, whose name has for a very long time been associated with the culture of the different *Sarracenias*, has an extensive group consisting mainly of these fascinating plants, associated with Palms and Ferns, and some pleasing examples of *Nertera depressa*. The *Sarracenias* are now grown to a much less extent than they formerly were.

An addition to the tuberous *Begonias* previously mentioned is a charming collection staged by an

Vuillermet (rich pink, much serrated), Ronsard (a striking flower, in colour rich pink, light centre, toothed at the edges), La Perle (white serrated), Lillie Moullière (a bright rose flower with a light centre, very pretty) and President Fallières (a huge truss of bright pink flowers).

Another collection, shown by M. Fargelon, contains some particularly good examples of blue-flowered forms.

M. George Arends, Ronsdorf, Bei Barmen, Germany, is showing a striking and varied assortment of *Primula obconica*, of which, by the way, there are many notable examples in the present exhibition.

In the Belgian Section, M. Van Houtte, Ghent, is exhibiting a choice group of Indian *Azaleas*, consisting of some of the finest varieties. Particularly noticeable are Jean Peeters (rich carmine), Roi des Blancs (white), Remembrance of Stephenson Clarke (vivid red), Flambeau (intense ruby red), Apollo (light scarlet), Louise Cuvelier (light striped), Professor Wolters (salmon rose) and Temperance (a very distinct lilac flower).

ORCHIDS.

It is true that we had heard glowing reports concerning the Orchids to be shown, but such reports were quite inadequate and failed to do justice

the *Cattleyas*, *Cymbidiums* and *Phalænopsis*. *Vanda teres gigantea*, *Dendrobium dalhousiana* and *Cœlogyne pandurata* are conspicuous in this meritorious group.

Messrs. Stuart Low and Co.'s group in Class 68, species only, is a comprehensive one, and contains representatives of most species worth growing. Just under one hundred species are to be seen in this collection alone.

By a consensus of opinion the Orchid Tent is one of the features of the exhibition; it is heated throughout by an efficient system of hot-water pipes.

Messrs. Sander and Son's extensive group occupies a run of about one thousand feet of staging, and contains some of the most beautiful Orchids in cultivation. It will be noticed that *Phalænopsis* and *Renanthera*, white and orange scarlet respectively, contrast in a most pleasing manner, while *Cattleya Schröderæ*, *Odontoglossums* and *Dendrobiums* in variety are shown in the height of perfection and in great profusion. In the centre-piece of this group will be observed a bold display of *Miltonia vexillaria Empress Augusta*; it is a conspicuous variety with large, deep pink-coloured flowers. The group is staged in a masterful manner, each plant shown to the greatest advantage against a background of Palms. The handsome yellow *Anguloa Clowesii* and the pure white *Dendrobium Dearii* are both conspicuous in this collection.

Messrs. Mansell and Hatcher are the only competitors in Class 66 for a group not exceeding 500 feet, and this contains a grand lot of *Renanthera imschootiana* and *Cattleya Mossiæ* and *Lælio-Cattleya* hybrids in variety. A new *Odontioda* named *Cleopatra* is worthy of special note, also a spotted *Anguloa*, a probable new species of doubtful origin. Two magnificent plants of *Vanda teres*, each carrying seventeen spikes, reflect the highest praise upon the cultivation.

The group by Mr. Ogilvie, containing *Cattleyas*, *Thunias*, *Odontoglossums* and *Dendrobiums*, and covering a space 500 feet in length, is worthy of the highest praise; and the same may be said of the group by Mr. Harry Dixon of Wandsworth Common, which, by the way, contains a wonderful specimen of the Spider Orchid (*Oncidium phymatochilum*); it has four floriferous spikes carrying in all 320 flowers.

Messrs. Armstrong and Brown in Class 83 have a well-staged group, in which *Cymbidiums* and *Cattleyas* form the leading feature.

The comparatively new race of Orchids known as *Odontiodas* forms the chief feature of a wonderful collection sent by Sir Jeremiah Colman, Bart. One plant of *Odontioda Bradshawia* alone carries over one hundred flowers, and the whole group of them originally came from one seed-pod raised in 1906. We particularly ask our readers to look out for *Odontioda Bradshawia* variety *Vivid*; it is a very beautiful and unusual scarlet variety. The *Gatton Park* variety is also worthy of special note, and it is one that secured a first-class certificate at the Temple Show last year. *Odontiodas Vuylsteckæ* and *Lady Colman* are two of the most valuable in the collection. But other Orchids are to be seen in this group, and among them we observed *Odontoglossum Queen of Gatton*, *O. Rolfæ* and *O. crispum* variety *Mary Colman*, *Oncidium pulchellum* and *O. splendens*, *Miltonia lævis*, *M. vexillaria magnifica* and *M. v. Empress Augusta*, *Lælio-Cattleya G. S. Ball*, *L.-C. Ruby Gem* and *L.-C. Phœbe*, *Lælia purpurata gloriosa* and *L. tenebrosa*, *Cattleya Mendelii* and a host of others, including *C. Fascinator* and *C. Mossiæ* in variety.

THE CENTRE OF LIEUTENANT-COLONEL SIR GEORGE HOLFORD'S GROUP OF ORCHIDS, AWARDED THE KING'S CUP FOR THE BEST EXHIBIT IN THE SHOW.

amateur, namely, F. Davis, Esq., Woolas Hill, Pershore, Worcester. This collection contains some very fine forms.

Yet another group of *Hippeastrums*, besides those previously noted, is contributed by W. B. Kenrick, Esq., Edgbaston, Birmingham. They are magnificently grown and the flowers of large size and good shape, the rich-coloured blossoms being particularly good.

FOREIGN EXHIBITS.

The number of stove and greenhouse plants among the foreign exhibits is decidedly limited; certainly not nearly as many as one might expect to have seen.

Of the French Section, the most striking group of this class is a collection of new and newer varieties of *Hydrangea*, shown by M. Moullière, one of whose older varieties, *Mme. Moullière*, has already attained a considerable amount of popularity in this country. Of the numerous examples, the following are especially noticeable: *Directeur*

to the magnificence and splendour of even the first glimpse of the interior of the Orchid Tent. Here are to be seen Orchids from all parts of the country, and such a display has never been excelled for brilliance and quality. It is worth travelling far to see the magnificent group sent by Sir George Holford. *Cattleyas* in the richest hues of crimson and mauve, and a multiplicity of varieties of *Dendrobiums*, *Cymbidiums* and *Lælio-Cattleyas*, are overhung with arching sprays of golden yellow *Oncidiums* against a background of stately Palms. It is a perfect mass of flowers, remarkable alike for quality and quantity, and reflecting the highest credit upon Mr. Alexander, the able grower.

Visitors must not fail to notice the grand lot of *Vanda teres* shown by Mr. Leopold de Rothschild, Gunnersbury Park Gardens (gardener, Mr. Reynolds).

Mr. Gurney Fowler is showing a creditable group of *Odontoglossums*, *Phalænopsis* and *Cymbidiums*, also very choice varieties of *Odontioda*.

Messrs. Cypher and Son's group, occupying a run of 400 feet, is remarkable for the excellence of

But this is not the only group sent from Gatton Park, for Orchids of botanical interest are likewise shown. The public who are seeking weird varieties and curiosities, or plants carrying minute flowers, will find them represented by the following: *Bulbophyllum tremulum*, *B. barbigerum*, *Masdevallia xiphoides* (with its sensitive lip which gives a jump soon after being touched), *M. o'brientiana* (very similar to the curious *M. Simula*, commonly known as the Partridge in the Grass from the difficulty of discovering the flowers among the foliage), and *Pleurothallis macroblepharis*, or the Gnat Orchid. These are all in the botanical group, Division 3, Class 86. An Orchid to be specially noted is *Bulbophyllum virescens*, with its exquisite colouring. Another of the plants, the peculiar *B. Lobbii*, with an ever-moving lip, is sometimes called the Lady Orchid, suggestive of a constantly wagging tongue. Mr. J. Collier, the Orchid-grower, deserves the highest praise for these interesting groups.

Words fail to express in adequate terms the magnificence of the large group by Messrs. Charlesworth and Co. of Hayward's Heath. This group comprises *Miltonias* remarkable for their size, colour and general good quality; *Cattleyas* and *Odontoglossums* of the very highest order; while an imposing group of *Odontiodas* in richest hues of orange and crimson, intermingled with bold white spikes of *Phalaenopsis*, is most effective and forms a grand centre-piece to a truly magnificent display.

FERNS.

Just within the main entrance on the right-hand side will be seen one of the finest groups of Ferns one could ever wish to see. It is by Messrs. H. B. May and Sons, and comprises all the greenhouse Ferns worth growing, together with choice British species and varieties. No less than a 2,500 feet run of space is taken up by this colossal collection. Tree Ferns are dotted here and there in this huge bank of greenery. The Stag's-horn Fern is freely used, and magnificent specimens of *Davallia solida superba*, *Polypodium Knightæ*, *P. Mayii* and *P. Vidgenii* (an old species from Queensland reintroduced) are to be seen. No fewer than thirty species and varieties of Filmy Ferns under bell-glasses are included in this wonderful collection.

Messrs. J. Hill and Son, Lower Edmonton, are represented by two groups of grand rare exotic Ferns, including *Polypodium Knightæ*, *Blechnum braziliense*, *Platynerium Veitchii*, *P. grande* and *P. Willinckii*; also *Polypodium quercifolium*, *Dicksonia* (*Cyathea*) *Barometz* and *Cyrtomium Rochfordii*.

A choice collection of exotic Ferns is shown by Messrs. James Veitch and Sons, Limited. Among

the most interesting are *Adiantum farleyense* and its near ally *Glory of Moordrecht*, *Asplenium Nidus*, *Davallias fijiensis elegans* and *robusta*, *Osmunda palustris*, *Platynerium Aleicorne*, *grande* and *Veitchii*, *Polypodium Knightæ* and *Pteris Childsii*.

A fine bank of hardy Ferns from Mr. Amos Perry is to be seen in No. 4 Tent. The group comprises a fine assortment of Royal and Hart's-

greenhouse Ferns in No. 6 Tent. *Adiantum farleyense* and *Nephrolepis Marshallii*, both in thumb pots, are remarkably good. Visitors should note the gold and silver Ferns (*Gymnogrammas*), the Climbing Fern, or *Lygodium japonica*, and the Coral Fern, *Gleichenia longipinnata*, and its near relative *G. flabellata*.

Mr. W. A. Manda, South Orange, New Jersey, U.S.A., is showing some magnificent specimen Ferns in Class 94, for 200 square feet. Among his best plants are *Polypodium mandaianum* (new and sterile), *Nephrolepis President Roosevelt* and *N. viridissima*. *Polypodium mandaianum* is also well shown in the class for specimen Ferns. It is a novelty worth noting, with handsome fronds six feet and more in length. These Ferns look none the worse for their journey of 3,000 miles.

ODONTIODA QUEEN MARY, A BEAUTIFUL NEW ORCHID SHOWN BY MESSRS. CHARLESWORTH AND CO.

tongue Ferns, also *Polypodiums*, *Athyriums* and *Polystichums*. Among the best plants are *Athyrium Filix-femina todæoides*, *Adiantum pedatum*, and *Polystichum angulare frondosum* Lowii.

Mr. H. N. Ellison, West Bromwich, is showing an admirable collection of *Adiantums* and other

the Embankment end of the large tent. Here are displayed in wonderful variety many of the more interesting and better subjects, such as Golden Oaks, Japanese Maples, large specimens of avenue trees, such as Limes, Norway Maples, Golden Elms, Purple and other Oaks, *Kæmpferia* and Maples in variety

TREES & SHRUBS.

Quite remarkable and most interesting is the large group of new Chinese plants collected by Mr. E. H. Wilson. This group is set up by Messrs. James Veitch and Sons, Limited, Chelsea, S.W., and covers no fewer than 2,000 feet. Vines are displayed in charming variety. *Rubus flagelliformis* is exhibited, and is one of the most beautiful of the Chinese climbing plants. Hollies are also most noteworthy, *Ilex Fargesii* and *I. continentalis* both being conspicuous for their distinct character. *Ilex Peryi* is another unique variety. The Chinese Walnut (*Juglans cathayensis*) is shown with young fruits just developing. There are some beautiful *Berberis* in this group of novelties, those worthy of notice being *B. Gagnepainei* and *B. Wilsonæ*, which is covered with coral red berries in the autumn. A beautiful evergreen *Berberis* is *B. verruculosus*—this is to be seen in excellent condition. *Astilbe Davidi* and *A. grandis* are two fine plants that are just developing their spikes of blossom. The foregoing are just a few of the plants that are destined to add to the attractiveness of the garden and landscape in the near future.

Trees and shrubs are shown in a charming manner by Messrs. Fisher, Son and Sibray, Limited, Handsworth, Sheffield. This firm have an excellent reputation for the better subjects under this heading, and their present exhibits serve to maintain their reputation. A group of beautiful *Acers* was much admired; but their chief exhibit is at

Exceptionally fine are *Dimorphanthus alba* and *D. aurea*, which give one the impression of making large and handsome trees. A groundwork of *Rhododendrons* adds to the effect of this fine group.

Clipped trees and bushes are always a feature at the great shows of this country, and on the present occasion they are well done. One collection represented peacocks, tables, crowns, stags and numerous other devices in well-grown specimens of Box and Yew; and in the same group beautiful Bays are exhibited in the pink of condition in standard, pyramid and other forms of culture. The foregoing come from Messrs. Jackman and Sons, Woking, Surrey, who are renowned for their topiary work.

Among the most noteworthy features of this memorable exhibition are the magnificent groups of *Rhododendrons*; all the leading specialists are represented. Exceptionally beautiful are the *Rhododendrons* from Messrs. John Waterer and Sons, Bagshot, Surrey. Their group covers an immense area, and represents these showy plants at their best. Pink Pearl is finely shown, as are the newer *Coronna* (a beautiful flesh pink sort), *Duchess of Connaught* (marked green on white ground), *Mrs. Holford* (a very beautiful rosy red), *W. E. Gladstone* (a very noble-looking flower), *Cynthia* (a deep rose), and *Doncaster* (a brilliant scarlet-crimson sort, bearing a most profuse display of blossoms) are among the best. Standards and bush specimens are charmingly displayed, and, as a whole, the exhibit is most comprehensive.

A bright and pretty group of *Rhododendrons* is that from Messrs. Fletcher and Brothers, Otter-shaw, Chertsey, Helen Paul (pale flesh pink), John Bennett-Poë (rich rose) and Duke of York (flesh pink, with large individual flowers) being the more novel sorts among an interesting collection of freely-flowered plants.

A remarkably fine collection of gorgeous plants of the hardy *Azaleas* is one of the special features of this great show. *Azalea mollis*, *A. m. sinensis*, *A. rustica*, *A. ponticum* and Ghent *Azaleas* are represented by freely-flowered plants in wonderful variety. Of *A. mollis sinensis*, variety *Apple Blossom*, *Prince of Orange* and *Dr. Reichenbach* are magnificent; of the Ghent *Azaleas*, variety *occidentalis* and *o. Exquisita* (new) are superb, besides an immense array of glorious things far too numerous to mention. This group is set up by Messrs. R. and G. Cuthbert, Southgate, Middlesex, and the arrangement and composition of the exhibit leave nothing to be desired.

A pretty group of hardy *Azaleas* is also shown by Messrs. Cutbush and Son, Highgate and Barnet. Profusely-flowered specimens of many varieties of all the well-known species and hybrids are in evidence in a charming group.

Hardy *Azaleas* from Messrs. J. Veitch and Sons make a grand bank of colour, the plants being large, freely flowered and beautifully fresh. A grand bank of *Lilacs* from this firm creates a most cool and refreshing effect. The plants are fresh, clean and profusely flowered, and there is great variety.

Messrs. Hugh Low and Co., Enfield, have a capital representation of the Bottle Brush Tree, in good form and condition, set up in their large and comprehensive group at the north end of the big tent. Both the original and the white forms are exhibited in standard and bush plants, as well as in pyramidal form.

In the Dutch Section hardy *Azaleas* are most artistically grouped by Messrs. M. Koster and Sons, Boskoop, Holland. Our Continental friends

have the advantage over English exhibitors of being able to set up their plants with real artistic effect, and the creation made by this firm is distinctly pleasing and almost fascinating. The colours of the flowers are superb, and this effect is heightened by the association of beautiful deep-coloured Japanese Maples. Queen Alexandra, Falstaff, King Lear, T. C. van Tol, Ellen Cuthbert and Laertes are all very beautiful.

A large and comprehensive collection of *Lilacs* and *Roses* are exhibited in the Dutch Section by the growers of these subjects at Aalsmeer, Holland, representing the products of the growers in this locality. The *Lilacs* are set up in very large gilded baskets in a most artistic way, and the

LEPTOSPERMUM SCOPARIUM NICHOLII,
SHOWN BY THE REV. ARTHUR T.
BOSCAWEN. (See page 261.)

group, as a whole, is charming in every way. Lilac-coloured sorts are Charles Dix, President Grevy and Souvenir de Louis Spath. White sorts are Marie Legraye and Marie Lemoine, the latter being a beautiful double variety.

Messrs. John Jefferies and Son, Limited, Cirencester, stage a very excellent group of conifers in wonderful variety in a space 500 feet square. The specimens have been lifted, and are set up in baskets. Many individual specimens merit high commendation, and the group embraces numerous choice and beautiful examples of coniferous plants. *Abies Veitchii*, *A. pungens*

glauca kosteriana pendula, *A. arizonica*, *A. pungens glauca*, *Cupressus lawsoniana gracilis*, *C. l. pyramidalis alba spica*, *Cedrus Deodara aurea*, *Cupressus lawsoniana Olbrichii*, *Picea nordmanniana*, *Abies albertiana*, *Thuja Lobbii siddingtonensis*, *Sciadopitys verticillata*, *Taxus elegantissima*, *Cupressus lawsoniana filiformis elegans*, *C. l. lutea gracilis* and *C. l. Stewartii* are some of the more noteworthy specimens of these wonderful trees.

In a competitive class for twenty-five conifers, distinct, *Taxads* excluded, Messrs. John Waterer and Sons have a very beautiful exhibit. The group is set up under the trees in the main avenue, and the plants are most attractive. The better specimens are *Abies concolor*, *A. lasiocarpa*, *A. pectinata pendula*, *A. nobilis* variety *glauca*, *A. nordmanniana*, *Juniperus virginiana glauca*, *Tsuga Sieboldii*, *T. mertensiana*, *Pinus contorta*, *P. Coulteri*, *P. muricata*, *Cupressus lawsoniana* variety *densa gracilis*, *Picea pungens*, *P. p. orientalis*, *P. polita* and *Abies sachalinensis*.

Bays as shown by Messrs. James Veitch and Sons, Limited, Chelsea, are exhibited in a manner never seen before. Two triangular corners on the lawn outdoors serve to display an extremely large assortment of specimen trees and bushes growing in tubs, and the plants are all in the pink of condition. Pyramid bushes and large and medium sized mop-headed or standard specimens are disposed on the grass in a charming way, displaying the beauty of this subject most effectively.

Ornamental trees and shrubs are charmingly set up by Mr. L. R. Russell of Richmond and Tunbridge Wells. A secluded spot in the outdoor garden, with a natural setting of dark foliage, displays these variegated and ornamental trees and shrubs in a manner seldom seen at these great shows. Here are to be seen beautiful specimens, showing the possibilities of the subjects when planted in their permanent positions. A few of the most noteworthy plants are *Vitis* in variety, Japanese Maples, *Ceanothus*, *Cytisus*, American Maples, Bamboos and numerous other ornamental trees and shrubs. This fine group is enhanced by a grand collection of Tree Ivies in grand condition, the colour being most noteworthy. *Hedera dentata variegata* is a beautiful Ivy that stands out in significant fashion. An imposing group of *Bambusa*, *Arundinaria* and *Phyllostachys*, set up by the same exhibitor, is a noteworthy exhibit. The graceful and decorative value of these plants is borne in upon the visitor as each subject in the group is inspected in turn, and there is little doubt such an exhibit must tend to make the Bamboos, &c., increasingly popular. The group comprises an area of 300 feet.

Messrs. W. Cutbush and Sons, Highgate and Barnet, have been for so long associated with the development of topiary work that their large and comprehensive display of clipped trees and shrubs comes as no surprise. The specimens are in a beautifully fresh condition, and they include Box in fresh green growth, Yews and Bays, peacocks, pheasants, anchors, stags, ships, tables and numerous other devices being remarkably well done.

Superbly fine is the group of Japanese Maples from Messrs. John Waterer and Sons, Limited, Bagshot. Handsome individual specimens, as well as dainty plants, are represented in this noteworthy exhibit of 300 square feet in the competitive classes. Exceptionally fine specimens

of *Acer palmatum dissectum*, *A. p. purpureum* and *A. japonica aureum* are most conspicuous. *A. crataegifolium*, *A. septemlobum* and *A. palmatum lutescens* are also very fine. A non-competitive group from the same firm of about 4,000 feet, representing *Kalmias*, *Viburnums*, *Rhododendron odoratum*, Thorns, Hollies, standard and pyramid, conifers in great variety, besides Maples and numerous other noteworthy plants, are in evidence. *Retinospira recta*, *R. obtusa densa aurea* and *R. filifera* are three magnificent conifers.

A group of flowering and foliage plants arranged for effect, to cover a space not exceeding 400 square feet, found two entrants, which, as a whole, was a beautiful diversion from the many other subjects arranged in close proximity. The group from Mr. R. C. Notcutt, The Nursery, Woodbridge, Suffolk, was a capital effort, although somewhat too crowded to do justice to the numerous plants set up. Flowering plants largely preponderated, the most conspicuous and noteworthy of these being *Oleari astellulata*, *Viburnum plicatum*, *Cytisus prostrata grandiflora*, *C. andreana* and *C. andreana prostrata*, *Spiraea confusa*, *Fabiana imbricata*, *Philadelphus Bouquet Blanc*, *Rhododendron Pink Pearl*, *Kalmia latifolia*, *Deutzia Lemoinei* and *Cytisus purpureus incurvatus*; of the foliage plants, *Acer palmatum rosea marginata*, *Cornus mas elegantissima* and *Prunus Pissardii*.

In the same competition as the foregoing Messrs. Fisher, Son and Sibray, Limited, Handsworth, Sheffield, set up a very dainty and artistic group. The disposition of the different subjects leaves nothing to be desired. Of the foliage plants the more noteworthy are *Ginkgo biloba*, *Cotoneaster Franchetti*, *Dimorphanthus aurea* and *D. alba*, *Rhododendron Countess Fitzwilliam*, Japanese Maples in variety, Japanese Vines, Tree Ivies, and the new *Aucuba japonica* Fisher's variety, all of which combine to make a beautiful group in conjunction with flowering plants of a diverse kind. The artistic disposition of the plants in this group is very noticeable, and the effect is most pleasing.

Outside, near to the Administration Offices, Messrs. W. Fromow and Sons, Chiswick, W., have a group of hardy trees and shrubs, mainly Japanese Maples. There is much to interest lovers of beautiful trees and shrubs in this group, and the disposition of the subjects is effectively carried out.

A group of hardy flowering trees and shrubs is shown outdoors near to the area devoted to rock gardens. This is set up by Messrs. Jackman and Son, Woking, and represents a great variety of plants that should succeed well in the neighbourhood of large towns. Among other useful subjects are Tree Ivies, Box, Yews, Hollies, Elders, Maples, Berberis, *Prunus Pissardii*, *Viburnums*, *Laburnums* and many useful plants for gardens in smoke-laden areas.

Superb aptly describes the group of conifers charmingly disposed by Messrs. John Waterer and Sons, Limited, Bagshot. This is a most praiseworthy exhibit, and includes a thoroughly representative series of plants. The grouping is especially effective, and under the cool and shade of the trees of the main avenue this display of 500 feet of these beautiful subjects looks most effective—*Retinospira obtusa Crippsii*, *Thuja occidentalis* variety *Douglasii*, *Cupressus lawsoniana* variety *Wissellii*, *Juniperus virginiana* variety *tripartita*, *Retinospira obtusa nana aurea*, *Abies arizonica*, *Thuja orientalis* variety *semperaeurens*, *Tsuga mertensiana*, *Pinus Cembra*, *Abies Veitchii*, *Picea Pinsapo* and *P. Omorika*, besides a host

of choice things. The same firm staged a charming group of variegated, golden, silver and glaucous conifers in a space 250 feet square. The specimens in this instance are most attractive and beautifully diversified in their character. This is to be seen in the main avenue outdoors under the trees. Among other noteworthy specimens are the following: *Tsuga canadensis* variety *alba spica*, *Juniperus communis* variety *alpina aurea*, *J. japonica* variety *aurea*, *Pseudotsuga Douglasii* variety *glauca elegans*, *Cupressus nootkatensis* variety *albo-variegata* and *C. pisifera* variety *aurea*.

Four hundred feet of Hollies from Messrs. John Waterer and Sons, Limited, Bagshot, make a magnificent exhibit. In this collection are many species and beautiful varieties of the originals. The group is displayed in the main avenue under the trees, and is most effective. *Ilex latifolia*, *I. Pernyii*, *I. cornuta*, two fine specimens of the species of Silver Weeping and Golden Weeping *I. Wilsonii*, *I. Mundayii*, *I. Aquifolium* variety *Golden King*, *I. crenata*, *I. c.* variety *aurea* and *I. Aquifolium* variety *Watereri*, better known as *Waterer's Golden Holly*, are shown. Of the green-

which is seen to advantage under the subdued light of the trees in the main avenue. *Rhododendron Pink Pearl*, hardy Azaleas and *Ceanothus divaricatus* are to be seen well disposed among a host of beautiful hardy foliage plants. *Pittosporum engenoides*, *Elæagnus japonica macrophylla*, *Cedrus Deodara* variety *aurea*, *C. D. alba spica*, *Acer palmatum sanguineum* and *Griselinia macrophylla* are some of the more interesting subjects in this exhibit.

Messrs. G. Paul and Son, Cheshunt, Herts, conceived the excellent idea of grouping a number of competitive classes together for effective purposes, and in this they are singularly successful. In this wonderful group there are 400 square feet of Hollies, twelve Taxads, two Portugal Laurels, twenty large specimen Hollies, each of which varies from 8 feet to 13 feet in height, and some are 7 feet in diameter. Noteworthy specimen Hollies are Weeping Silver (a splendid standard), *Ilex tortuosa* and *Waterer's Gold* (fine bush plants). The Yews are also very fine.

A most fascinating collection of clipped trees and shrubs from Messrs. J. Piper and Son, Bayswater, calls for special mention. Birds in variety,

AZALEAS SHOWN BY MESSRS. R. AND G. CUTHBERT.

leaved varieties, additional sorts are *I. doningtonensis*, *I. ferox*, *I. Sheppardii* and *I. camelliaefolia*, all of which contribute to a group that is somewhat unique.

Messrs. Liberty and Co., Limited, have a most interesting exhibit of Japanese ornaments and dwarf trees in wonderful variety in the main avenue under the trees. Here are to be found Japanese ornaments for the garden in stone, bronze and Bamboo, besides quite a good collection of their dwarf trees, which have become so popular of late. This exhibit is meant to illustrate the accessories of a Japanese garden, and this it does most effectively.

A group of conifers arranged on a space of 500 square feet is shown by Messrs. Jackman and Son, Woking, Surrey, and this embraces a most charming and beautiful selection of plants in tubs in splendid condition. The disposition of the different subjects leaves nothing to be desired. As a collection of coniferous subjects the group is splendidly representative, many noteworthy examples being in evidence.

Messrs. Dicksons, Limited, Chester, have a large, clean and bright group of hardy trees and shrubs,

spiral Yews, hoops, baskets, vases, a loving-cup, a dog and numerous other devices are displayed. The whole collection is enclosed in a fence of live Box, the round pillars and upright staves being represented in a unique manner. This group is in the competitive class, and is arranged outdoors.

In addition to a charming group of *Rhododendrons* mentioned elsewhere, Messrs. Jackman of Woking, Surrey, have a series of groups of other subjects at the north-east end of the big tent. Here are to be seen artistically-arranged exhibits of Clematises, hardy Azaleas, a group containing *Kalmias*, *Hydrangea*, *Viburnums*, *Weigela*, *Philadelphus*, *Spiræas*, *Andromedas*, *Cytisus*, *Laburnums*, *Phlomis*, *Escallonia* and *Ceanothus*, and another group of herbaceous plants. The group of Clematises has an especial cooling effect; the plants are in excellent condition and bear beautiful blossoms. *Lady Northcliffe*, *Mary Boislett*, *Lord Neville*, *Jackmanii rubra*, *Nellie Moser*, *Belle of Woking* (double), *King Edward VII.* and *Mrs. Hope* are among the best sorts in evidence.

A wonderfully varied collection of new trees and shrubs is exhibited in the large tent by the Hon. Vicary Gibbs, Aldenham House, Elstree,

Herts. This group promotes considerable interest, as the plants were raised from seeds collected by Mr. E. H. Wilson during his last two journeys to China. The seeds were gathered from trees and shrubs growing at high altitudes, so that their fitness for cultivation within the United Kingdom is practically assured owing to this fact. Notable specimens among this large and varied collection of plants are *Cedrella sinensis*, *Ailantus vilmoriniana* and a new *Paulownia*. The plants are shown in pots, and many of the *Rubuses* are less vigorous than when growing in the open. Other noteworthy shrubs in this exceedingly interesting collection are *Acer Henryii*, *A. Davidii* and *A. Wilsonii*, a capital trio. A beautiful climber, now fairly well known, is *Actinidia sinensis*. Distinct and attractive *Alders* are *Alnus lanata* and *A. cremastogyne*. Other subjects, such as *Berberis*, *Deutzia*, *Cotoneasters*, *Corylopsis*, *Rhododendrons*, *Ribes* in variety and a beautiful series of ornamental Vines, are included in this large and comprehensive group, for each of which there are many uses.

HARDY HERBACEOUS PLANTS AND ALPINES.

This section is exceedingly well represented in all classes, not a few of the exhibits proving of great excellence. In the large non-competitive class of some 300 feet in extent, no exhibitor brought or staged such an admirable lot of alpine and hardy plants generally as Sir Everard Hambro, K.C.V.O., Hayes Place, Hayes, Kent (gardener, Mr. J. Grandfield), the collection comprising one of those rich and extensive displays of alpine vegetation which have made the Hayes collection famous in many places where these things are grown. Singularly rich in mountain plants generally, we direct particular attention to such rarities as *Erinacea pungens*, *Jankaea Heldreichii*, *Asperula suberosa rosea*, *Primula Veitchii*, *P. cockburnana* and other choice species. *Oenothera ovata* was a charming plant in this group, while the almost endless array of *Saxifrages* and *Androsaces* added lustre and greatness to Hayes and its associations with alpine plants.

In No. 2 Tent Messrs. Wallace and Co., Colchester, have arranged a delightful lot of *Ixias*, *Sparaxis*, *Brodiaeas*, *Liliums* and *Calochorti*, the latter embracing a delightful array of colour and form in these too rarely seen Californian bulbous plants. The finest plant in the group in all probability was *Lilium myriophyllum*, a delightful trumpet Lily from China with very narrow leaves.

In the group from Messrs. Thomson and Charman, Bushey, are to be seen excellent examples of *Saxifragas*, *Primulas* and the not ineffective *Mimulus radicans*.

In this same tent Messrs. Artindale and Sons, Sheffield, have a charming lot of things, well grown and pleasingly arranged. The examples, too, for the most part, were in specimen form, and in this way the plants told their own tale. *Cypripediums* of the hardy kinds, as *C. pubescens*, *aculea parviflorum* and *montanum* are all represented in the group, while such things as *Primula lichiangensis*, *Onosma alba rosea*, *Phloxes* in variety and *Aquilegia glandulosa* were all important items in this fine group of plants.

Messrs. Kelway and Sons, Langport, in one of the large tents have a delightful lot of single *Pyrethrums*, *Gaillardias*, *Heucheras* and *Tree Pæonies*. The *Pyrethrums* are a rich and telling lot, delightful in their variety, pleasing in their colour and beauty.

Queen Mary (pink flower), Mrs. W. Kelway (single pink), Langport Scarlet and *Cassiope* are among the finer forms worthy of attention in this fine lot of hardy herbaceous flowers.

Messrs. Lilley, Guernsey, have a pretty and unusual display of *Sparaxis*, *Irises*, *Gladioli*, *Brodiaeas*, *Ixias* and the like, and the group is worthy the attention of our readers by reason of its variety, excellence and beauty.

Messrs. Rich and Co., Bath, have a very pleasing arrangement of *Pyrethrums* in Tent No. 2, and all interested in these showy hardy flowers should search them out and see what they have in store for the hardy plant garden generally.

Near by, Messrs. G. and A. Clark, Limited, Dover, have a showy group of *Irises*, *Thalictrums*, the new double *Geum* Mrs. J. Bradshaw and a very charming lot of single *Pyrethrums*, which are showy in the extreme.

Messrs. Harkness and Sons, Bedale, Yorks, have a very handsome exhibit of *Verbascum*s, *Lupines* and *Globe Flowers*, the latter including such things as *His Majesty*, *Gold Crest*, *Bessie Walker*, *Triumph* and *Miss Willmott*. *Verbascum International* (a yellow bronze variety of great size of blossom) is also to be seen on the stand of this firm.

The *Eremuri*, *Iris*, *Trollius*, *Phlox*, *Verbascum* and *Lupines* from Messrs. Artindale, Sheffield, are well worthy of inspection, and as a showy lot will well repay a little study.

From the famed nurseries of Messrs. George Bunyard and Co., Maidstone, have come a superb lot of *Oriental Poppies*, *Pyrethrums*, *Eremuri*, *Lupines*, *Ixias*, *Verbascum*s and other plants, the whole making a sumptuous gathering of the best hardy flowers of the moment.

In this same tent, Mr. M. Prichard, Christchurch, again excels, and his stand of *Iris*, *Eremuri*, *Pyrethrums*, *Pæonies*, *Lilies* and *Poppies* are things to look for, things to admire, and something to remember.

Mr. Reginald Farrer, Craven Nursery, Clapham, Yorks, has one of the choicest exhibits in the entire show, a group rich in alpine, dominating in cultural excellence and appealing by reason of rare beauty and merit. It is one of the collections of alpine to which we would send all our readers; one also wherein much of the charm of alpine vegetation will be found, and from which may be gathered much useful information. Of the more noteworthy examples we may instance the lovely *Tyrolese Daphne rupestris*, with its crowd of pink blossoms above a tuft of growth 3 inches or so high, which is a gem of the first water sufficient to charm and delight all lovers of these plants. *Edraianthus serpyllifolius major*, with its mass of royal purple bells strewn the floor, and overtopped by graceful panicles of *Saxifrages*, is something to look for and something to remember. It is suggestive, too, in its garden effect and beauty. *Ramondias*, *Haberleas*, and *Primula farinosa*, in a rich and delightful colony, constituting, as it were, the herbage of moist upland pasture, is a sight alone. *Ranunculus parnassifolius* is a serenely pure and lovely white alpine, while the *Trilliums*, *Cypripediums*, *Ramondias*, *Haberleas*, *Campanula Allioni*, *Androsaces* and *Primulas* constitute such a feast of these plants as is rarely got together. Choicest of the choice, this is one of the exhibits under canvas for which the alpine-lover must seek, and, having found it, make sure that he will not be sent empty away.

In a large Lily group, Messrs. Wallace and Co., Colchester, have arranged many of their finest

specimens, such species or varieties as *Hansonii*, *Batemannia*, *Leucanthemum myriophyllum*, *tenuifolium* and *japonicum colchesterense*, also known as *odorum*, appealing to the specialist at once. It is a veritable feast of the tribe, something not to be missed by those who seek for the best of everything.

VIOLAS.

Violas (Tufted Pansies) are shown by Messrs. W. Artindale and Son, Sheffield, as growing plants. Freely-flowered specimens growing in boxes call for special mention. Some sixty boxes are shown by this firm in the class for 100 feet of *Violas*, and they serve to illustrate the free-flowering propensity of these plants and their great diversity of markings and colouring. A few of the better sorts are *Moseley Perfection* (a grand yellow), *Lady Knox* (primrose), *Acme* (plum), *A. S. Frater* (white, edged heliotrope), and *Kathleen* and *Gladys Finlay* (two good fancy flowers).

A pretty series of twenty pans of growing plants are shown by Messrs. Whitelegg and Page, Chislehurst, Kent. In most cases the plants are flowering profusely, the more striking examples being *Acme*, *Peace*, *Councillor Waters*, *Mrs. Chichester*, *Bridal Morn* and *Marchioness*.

Messrs. Rich and Co., Bath, have a small exhibit of *Violas*. Individual blooms are placed in tubes let into velvet-covered boards. The effect was not good.

For the 100-foot group of *Violas*, Messrs. Gunn and Son, Olton, Warwickshire, are showing lifted plants packed tightly in round baskets, and in this way they make a most effective display. The best varieties are *Viola cornuta purpurea*, *Moseley Perfection*, *Colonel Wolferston*, *Madge*, *John Quinton*, *Bronze Kintore*, *Swan*, *James Pilling*, *Belfast Gem*, *J. Rowlands*, *Dr. McFarlane* and *A. J. Bastock*. The same firm are competitors in the class for twenty baskets of *Violas*, growing plants, showing specimens basketed in precisely the same way and many of the same varieties as are exhibited in the larger group. This firm has done well to keep their stock in such healthy condition.

SWEET PEAS.

NON-COMPETITIVE.—IN THE CUT FLOWER TENT.

Messrs. Dobbie and Co., Mark's Tey, Essex, are staging an excellent exhibit of *Sweet Peas*, both as cut flowers and growing on the plants. The latter, which form a natural background, are growing in boxes and are 9 feet high, comprising standard varieties and novelties. The cut blooms embrace *Dobbie's Scarlet* (a striking scarlet variety, carrying in nearly all cases four flowers on a spray), *Dobbie's Cream* (a large, well-formed flower), *Lady Miller* (apricot pink), *Brunette* (of a pure self mahogany colour), *Decorator* (a pleasing shade of old rose) and *Melba* (one of the largest *Sweet Peas* in cultivation, having flowers nearly three inches in diameter). Some splendid specimens of *Mrs. W. Cuthbertson* are staged, the sprays in question bearing from four and five to nine individual flowers on a spray, the largest of which is fasciated. *Lady Knox*, one of the best cream varieties, with buff tints, is in good form, and *Mauve Queen* was also noted.

Robert Sydenham, Limited, Tenby Street, Birmingham, have a representative collection containing several choice varieties. *Lilian* (pale salmon pink), *Barbara* (another pleasing shade), *Edith Taylor* (glowing rose), *Lady Evelyn Eyre*

(an improved form of Mrs. Hardcastle Sykes), Scarlet Emperor (a very strong-growing variety), Iris (salmon pink), Mrs. T. W. Warren (a waved form of Helen Pierce) and Charles Foster.

Another excellent exhibit is that staged by Mr. C. W. Breadmore, High Street, Winchester, and many well-finished blooms are shown. Special notice must be made of Aggie Elder (rosy cerise in colour and of good form and substance), Princess Mary (bright blue and shot wings, flowers being borne in fours), Lord Curzon (bright magenta), Flossie Jeffery (pale shrimp pink), and Iris (a deeper shade of the foregoing variety). Frilled Cream is denoted by its name, and is a seedling of the present year. A spray of Elsie Herbert is to be noticed bearing eight flowers.

Mr. C. W. Breadmore also stage a collection, comprising seventy specimens of Sweet Peas in all the best varieties, grown in tubs on "Simplicitas" netting.

Messrs. R. H. Bath, Limited, The Floral Farms, Wisbech, also have a special stand of Sweet Peas, notable varieties shown being Felicity (a variety which will be now shown as Mauve Queen, and is identical in colour with Dobbie's Mauve Queen, the latter variety securing a first-class certificate

of novelties of their own raising, the principal varieties being Helen Williams (picotee edged, and of a brighter colour than Mrs. C. W. Breadmore), Margaret Cook (a giant bicolor, pale old rose standard, and cream wings veined rose), The Lady (a fine, bold flower of perfect form), Fair Maid Improved (a giant Spencer, flesh on cream ground, a very pretty flower), Stark's Salmon (a robust grower which stands the sun well), Emmie Tatham Improved (a charming shade of old rose), Mrs. R. W. Pitt Improved (a bright crushed strawberry Spencer) and Florence Wright Spencer (pure white, of good form and substance).

Mr. C. W. Breadmore is showing a most interesting and varied collection embracing all the novelties which he has staged in his non-competitive group.

Mr. W. E. Alsen is staging the new double variety Annabel Lee (a pleasing lilac shade, with paler centre), Bobby Stewart (pale delicate lilac), Money-maker (pure white, a good flower), Minnie Furnell (a pleasing salmon pink), also a fine bunch of R. F. Felton, Melba, Stirling Stent and George Stark.

Messrs. Lumley and Co. are showing some varieties of excellent merit, including Veronique (a marbled Spencer of good form and striking

Holmes, Empress, Nubian, Zephyr, Elsie Herbert, Doris Usher and Freda.

For a group of Sweet Peas consisting of varieties sent out since September, 1910, there are two entries, the principal varieties being Nettie Jenkins, Royal Rose, Charles Foster, Dobbie's Cream, Elfrida Pearson and Empress.

Class 310: First, Mr. C. W. Breadmore; second, Mr. W. E. Alsen, Denmead Nurseries, Cosham, Hants; third, Messrs. W. Lumley and Co., Hayling Island, Hants.

Class 311: First, Sir Randolph Baker, Bart.; second, Mr. L. H. Hatting, The Nest, Hornchurch, Essex; third, the Birmingham Industrial School, Shustoke, Warwickshire.

FRUIT.

NON-COMPETITIVE. IN LARGE TENT.

The King's Acre Nurseries, Hereford, are showing an extensive collection of fruiting trees in pots, among which we noted some fine specimens of Apples, Pears, and Peaches, which are very good for the season; also a large trained specimen of Duke of York in a pot bearing several fruits. Figs are well to the fore, and the true variety of Osborn's Prolific is shown.

An excellent display was staged by Messrs. T. S. Rivers and Son, Sawbridgeworth, Herts, the well-known raisers and growers of many choice varieties. The visitor will not be disappointed on this occasion, as the new 101 Seedling Nectarine is well fruited and perfectly ready for table, being a week earlier than Early Rivers. This variety was raised from the white-flowered Nectarine, and we think will prove a useful variety for forcing work. A new second-early Peach, Kestrel, is also in good condition. A well-fruited specimen of Cherry, Guigne Annonay, is conspicuous. Plums are represented by Early Rivers, Curlew and Blue Rock, and Pears and Apples are well shown. Citrus are also an interesting feature as shown by this firm. Among the collection we noticed the Grape Fruit, White and Imperial Lemons, and Shaddocks. A very fine specimen of the Horned Orange, *C. corniculata*, also Maltese, St. Michael's and Seville varieties, and others with variegated foliage, are to be seen.

Leopold de Rothschild, Esq. (gardener, Mr. J. Hudson), Gunnersbury House, Acton, has arranged a most effective display for a private grower; it consists of a central avenue with a pergola, or series of arches, in the centre, which are covered with Virginian Creeper, and the top is ornamented with Vines bearing several bunches of Grapes, which are well finished for so early a date. The sides of the arches are made conspicuous by having fruiting Melons in pots at the base of each. These are remarkable for their healthy foliage, the two chief varieties shown being Eminence and Ringleader. Along both sides of the central avenue a large collection of pot fruit trees are staged, consisting of fifty varieties in thirteen kinds. Cherries, which are shown in twelve varieties, are a special feature. Peaches, Nectarines, Loganberry and Newberry, Strawberries, &c., make up the display.

Messrs. Laxton Brothers, Bedford, who are well known as Strawberry specialists and raisers, have the following new varieties to the fore: King George V., excellent for forcing, which it is anticipated will replace Royal Sovereign for this purpose, being a week earlier and of better flavour and colour than the latter, and a robust grower. Maincrop, for midseason work, has a very large, wedge-shaped fruit of exceptionally fine flavour. The Queen, considered equal

DECORATED TABLE OF DESSERT FRUIT SHOWN BY HIS MAJESTY THE KING IN CLASS 351. THIS WAS AWARDED THE GOLD MEDAL AND FIRST PRIZE, AND INCLUDED THE BEST FRUIT IN THE SHOW.

last year), Isabel (a pale pink of pleasing shade), Mrs. R. Hallam (creamy pink), Tennant Spencer (in good form), Scarlet Emperor, Edith Taylor, Dorothy (a charming pink shade), Thomas Stevenson (well finished), and Charles Foster (this variety coming remarkably well under glass).

Mr. J. Stevenson, Wimborne, is staging an extensive collection of up-to-date novelties, including T. Stevenson, Doris Usher (pink), Bertie Usher (blue flaked), Scarlet Emperor and Empress, May Campbell, Mrs. Cuthbertson and some good unnamed seedlings. All the Sweet Peas are in first-class condition. Indeed, it is really marvellous the colour, size and substance that growers have been able to impart to the flowers at such an early date, and the exhibits reflect the greatest credit on those responsible for the growing of the blooms.

COMPETITIVE. THESE EXHIBITS ARE STAGED IN TENT NO. 6.

Messrs. G. Stark and Son, Great Ryburgh, Norfolk, are staging an exhibit composed entirely

colour), The Abbot (a mottled pale chocolate variety), Mrs. E. Noakes, Avalanche and Constance Oliver.

Mr. J. Agate, Sea View Nurseries, Havant, has some good bunches of Captain Travers (bright orange), Mr. Herbert Lees (pink on a white ground), Barbara, Stirling Stent, Charles Stent (a large rose pink flower), Felice Lyne (a bright cerise shade which is very effective) and several other leading varieties.

Messrs. S. Bide and Sons, Farnham, also stage some good flowers, having a most interesting display.

Mr. J. Stevenson, Wimborne, also shows a collection in competition.

COMPETITIVE.—AMATEURS.

In the class for Messrs. Dobbie and Co.'s Cup, for a group of Sweet Peas not to exceed 6 feet by 3 feet, there are three entries. Sir Randolph L. Baker, Bart., Ranston, Blandford, has a very fine display, the varieties being Dobbie's Cream, Edrom Beauty, Hercules, Evelyn Hemus, Maud

in flavour to British Queen, which fruit it resembles in shape, is a robust grower and good cropper. The Earl is in every respect an improved Vicomtesse of similar flavour, a much larger fruit and as free a cropper. The Laxtonberry is a hybrid between the Loganberry and Raspberry, being quite as sweet as the latter, the fruit of which readily separates from the core, and has the habit of the Loganberry. Other specimens of fruiting trees of various kinds were staged.

IN THE FRUIT TENT.

Messrs. George Bunyard and Co., The Royal Nurseries, Maidstone, are staging a choice collection of seventy-five varieties of Apples, among which are to be noticed Farmer's Seedling, Blue Pearmain, Alverstone, well-finished, highly-coloured specimens of Smart's Prince Arthur (of large, conical form), Calville de Femmes, Calville Malingerie, Cox's Orange Pippin, Foster's Seedling, Belle Pontoise, Belle de Bois, Gros St. Clements and Sturmer Pippin. A handsome dish of Uvedale's St. Germain Pear is also shown.

Messrs. Storrie and Storrie, Glencarse, Perthshire, have a representative collection of hardy fruits as cultivated generally. They are also exhibiting Currants, fruiting in pots, in the following varieties: Black Naples, Red Dutch and White Transparent, finished off with a floral ground-work.

MELONS.

For the best-flavoured white-fleshed Melon, Mr. A. J. Thornhill secured first with a medium fruit of Hero of Lockinge, Mr. C. H. Beckett coming second with a larger fruit of the same variety, and the Horticultural College, Swanley, third with Elmcroft Beauty.

For a class of twenty-four Melons, not less than six varieties, Mr. C. H. Beckett, Chilton Gardens, Hungerford, stages a most excellent exhibit, which includes Countess and Barnet Hill Favourite; they are well finished and beautifully netted (first prize). His Grace the Duke of Westminster, Eaton Hall, Chester, also has a good display, which includes Eaton Seedling, Hero of Lockinge, Countess, Eminence, Cestrian and Scarlet Queen (second prize). Mr. C. F. Raphael, Porter's Park, Shenley, Herts, has a large exhibit of good fruits, the principal varieties being Universal, Ringleader and Royal Jubilee (third prize).

For one green-fleshed Melon, the Horticultural College came first with Emerald Gem, which is beautifully netted; Mr. W. B. M. Bird, Eartham House, Chichester, second with the same variety; and Mr. F. B. J. Wingfield Digby third with Buscot Park Hero.

For the best scarlet-fleshed variety, the Horticultural College led with a well-netted fruit of Superlative, Mr. C. H. Beckett coming second with Sutton's Scarlet.

For two varieties of Melons, one fruit of each, the Horticultural College took the lead with Superlative and Emerald Gem; second, Mr. F. B. J. Wingfield Digby with Hero of Lockinge and Greengage.

GRAPES.

For one black and one white variety, two bunches of each, the Marquis of Salisbury, Hatfield House, secured first with good bunches of Muscat of Alexandria and Black Hamburg. Mr. R. W. Perkins, Greenford, Harrow, obtained second with Black Hamburg and Foster's Seedling. Sir W. Greenwell, Marden Park, Caterham, took third with similar varieties.

For two bunches of Black Hamburg, the Trustees of the Duke of St. Albans (the Duke of Leeds), Bestwood Lodge, Arnold, obtained first with two well-formed and well-finished bunches. The Marquis of Salisbury came second and Mr. R. W. Perkins third.

For twelve bunches of Grapes, not more than three bunches of one variety, Lady Wantage was awarded first for a very pretty exhibit, including Madresfield Court, Foster's Seedling, Buckland Sweetwater and Black Hamburg; the bunches are beautifully staged, with an effective ground-work of Ferns.

For two bunches of Foster's Seedling, Sir W. Greenwell led with excellent bunches. Mr. R. W. Perkins came second and Mr. C. H. Beckett, Chilton Gardens, Hungerford, third.

His Grace the Duke of Portland, Welbeck Abbey, took the first prize for well-finished bunches of Foster's Seedling.

STRAWBERRIES.

For a dish of twenty fruits of Strawberries, the Earl of Lytton, Knebworth, Herts, came first, the Marquis of Salisbury second, and Mr. J. Adams, Leigside Nurseries, Lewes, third, all with Royal Sovereign.

For three varieties of Strawberries, Mr. F. B. J. Wingfield Digby, Sherborne Castle, Dorset, obtained second; no first was awarded.

For a collection of Strawberries, nine varieties, the Marquis of Salisbury took first with some splendid specimens of Bedford Champion, Leader, Royal Sovereign, Reward, Monarch, Utility, British Queen, The Bedford and Waterloo, all in excellent condition.

PLUMS.

For two dishes of Plums, distinct, the Duke of Westminster took first.

For a dish of Brown Turkey Figs, the Marquis of Salisbury led with well-coloured fruits, the Duke of Portland being second.

PEACHES AND NECTARINES.

For a collection of Peaches and Nectarines, three dishes of each, the Duke of Portland came first with some excellent examples of Duke of York, Alexander and Hale's Early Peaches, and Cardinal, Early Rivers and Lord Napier Nectarines.

For a dish of six Nectarines, the Trustees of the Duke of St. Albans led with Early Rivers, the Duke of Portland second with Cardinal, and Mr. C. H. Beckett third with the same variety.

For a dish of Peaches, the Duke of Portland took first place with Alexander, and the Trustees of the Duke of St. Albans second with Hale's Early.

For a collection of Peaches and Nectarines, three dishes of each, the Trustees of the Duke of St. Albans were awarded second with Peaches Hale's Early, Amsden June and Duke of York, and Nectarines Early Rivers and Cardinal.

COLLECTIONS OF FRUIT.

For a collection of nine dishes of fruit, His Majesty King George V. shows splendid examples from the Royal Gardens, Windsor, including some excellent bunches of Grapes Foster's Seedling and Black Hamburg of good size and quality, Melon Eminence, Strawberry Royal Sovereign, Plum Jefferson (beautifully finished), Duke of York Peaches, Cardinal Nectarines, Brown Turkey Figs and Black Tartarian Cherries. Second prize was secured by Mr. F. B. J. Wingfield Digby with a large fruit of Premier Melon, Foster's Seedling and Black Hamburg Grapes, and others.

For a collection of twelve dishes of fruit, the Duke of Westminster led with a fine collection, Grapes being represented by Muscat of Alexandria, Black Hamburg and Madresfield Court; Nectarines, by Early Rivers and Lord Napier; Peaches, by Royal George and Hale's Early; Plums, by Transparent Gage; Cherries, by Bigarreau de Meyel; Melon, by Marchioness, of good quality and fine form; and some highly-coloured fruits of Apple Lady Sudeley. Second prize was secured by the Marquis of Salisbury, who shows the only Pineapple staged of The Queen variety, a fine specimen of Universal Melon, Muscat of Alexandria and Black Hamburg Grapes, Royal Sovereign and Waterloo Strawberries, Hale's Early and Amsden June Peaches, Lord Napier and Early Rivers Nectarines, Brown Turkey Figs, and Early Rivers Cherries.

The premier class for fruit is that for twelve dishes of dessert fruit, not less than six distinct kinds, decorated with plants and flowers. His Majesty the King took the leading honours with a most magnificent display, embracing black and white Grapes of excellent size, quality and merit, the varieties being Black Hamburg, Foster's Seedling, Madresfield Court and Muscat of Alexandria, all magnificent; Melons Eminence and Superlative, Peaches Amsden June and Duke of York, Cardinal Nectarine, Brown Turkey and White Marseilles Figs and Royal Sovereign Strawberry, the floral decorations being composed of Orchids and Liliums, most tastefully arranged. An illustration of this exhibit, which reflected the greatest credit on the King's head-gardener, Mr. Mackellar, and his staff, is given on p. 267. The fruit was the best we have ever seen in May. Second prize was taken by the Duke of Westminster, who also stages a grand exhibit, having some fine specimens of Emperor Melon, Muscat of Alexandria and Madresfield Court Grapes, Early Rivers and Lord Napier Nectarines, Royal George Peaches and Brown Turkey Figs, the whole being tastefully decorated with Orchids and choice flowers. The Marquis of Salisbury was placed third with some good examples of Melons, Strawberries, Peaches, Nectarines, Figs and Cherries, decorated with Carnations, Liliums, Sweet Peas and Selaginella.

FRUIT IN THE OPEN.

Messrs. James Veitch and Sons, Limited, Royal Exotic Nurseries, Chelsea, S.W., have a most effectively-arranged exhibit of fruiting trees in pots, plunged in the grass, representing the various methods of training. The use of the Loganberry for pergolas is demonstrated in a practical manner. Another special feature are Pears trained as vertical cordons and planted in straight rows, with specially-trained trees for the end of rows in order to utilise the whole wall space. Well-fruited horizontal-trained examples are Beurré Rance and Doyenné du Comice, Gooseberries, Plums, Cherries, Quinces and Apricots are also included, and some fine specimen standard Apples, with Mistletoe growing happily upon them, are planted at the entrance to the central avenue of the exhibit.

Messrs. Laxton Brothers, Bedford, also show examples of trained fruit trees, growing in pots, of many and varied shapes, in all the leading kinds. Two interesting hybrids may be seen in this display—the Cherry Plum, which is a hybrid between the Cherry and Plum, and the Peach Plum, a hybrid denoted by name.

Messrs. Stuart Low and Co., Bush Hill Park, Enfield, have a collection of trained trees in a variety of forms and of the leading kinds.

CARNATIONS AND PINKS.

The display of all kinds of Carnations is very fine. I have carefully gone round all the tents and seen all that was to be seen; but, unfortunately, as I have to complete these notes at an early hour, there were still some few to be staged. In my judgment I think the honours of the show will fall to Mr. C. Engelmann of Saffron Walden. An old hand at growing Perpetual-flowering Carnations on a very big scale, and who pretty well knows what has been done both here and in America, told me that he thought Engelmann's group in Tent No. 4 (the large tent) for competition in Class 217 is probably the best group ever staged. It is magnificent; the quality of the flowers and their grouping leave nothing to be desired. A large vase of Felton's Japanese basket-work holds a huge bunch of Elecktra, a delightful pink-tinted orange bloom. Pillars of choice varieties flank it on either side, and some vases fill in the intervening spaces. In Tent No. 2 the same exhibitor has fine examples of his six 1912 novelties—Elecktra, Salome (a weird combination of pink and dull mauve), Sunstar (a bright yellow, flecked with pink, named after the Derby winner of 1911 because it was first shown at the Temple on the day the big race was run—not a bad idea for a lucky name!), British Triumph (a bright maroon), Rose (a bright rose) and Lady Northcote (a salmon pink, a most lasting flower when cut, and very free). It has just received a first-class certificate from the Perpetual Flowering Carnation Society. Of quite different types, but equally beautiful, are the exhibits of Mr. James Douglas and Mr. Blick. Both stage choice border varieties, many of which are quite new. In Tent No. 6 the latter gentleman has a group of cut blooms, the two most interesting flowers in which are Queen Mary (a very sweet-scented pink) and King George. These varieties were presented to the Queen a few days before the Coronation, and she honoured them by naming one after the King and one after herself. Visitors will say the Queen is no bad judge of good flowers when they see them. In Tent No. 4 Mr. Blick has a group in pots. Caradive (a glowing vermilion and pale orange Picotee), and Victory, a pale rose pink and buff, are very taking flowers. These two fancy yellow-ground Picotees appealed to me very much. Some day we will have similar things in the Perpetuals, I am told. Mr. James Douglas has some beauties in his group in Tent No. 5, and his competition vases will have to meet something very good indeed to be beaten. Jean Douglas is a "top-hole" scarlet border variety of excellent shape, with large, smooth-looking, unserrated petals. It is a fine garden plant; in fact, Mr. Douglas considers it a *nulli secundus*, and he should know. It has just been put into commerce. Mrs. Henwood is almost its counterpart in white as Miss Willmott is in pink. Elizabeth Shiffner is a splendid orange buff, which was sent out, I think, last year. It reminds one of the old Mrs. Reynolds Hole somewhat in colour. I was surprised to hear how much Pinks are coming into favour for border and rockery decoration. Mr. Douglas has two nice new ones with his Carnations in Tent No. 5; they are named Simplicity and Captivation, and Bookham Gem is one of the best "laced."

Mr. G. H. Herbert has twelve huge four year old plants of his special variety, Progress. Each of them bears from eighty to one hundred fine rosy mauve blooms. It is a grand doer, and its freedom of flowering can be judged from

twenty-four small pots which are along with it. On the extreme east (next the avenue) of the monster tent the pot plants are staged in attractive groups. Those of Mr. C. Turner of Slough, Mr. H. L. C. Brassey, M.P. (gardener, Mr. Fitt), Mr. Mount of Canterbury and Mr. C. F. Raphael (gardener, Mr. Grubb) are arranged along the side, and very well they look. Mr. Raphael's flowers (Class 216) are very large, fresh and beautifully arranged. Princess of Wales, which the gardener considers the best Malmaison there is, occupies a big centre, and at the top corners are clumps of the lovely red Lady Coventry, and correspondingly at the lower corners are the Old Blush and the new Duchess of Westminster. Hard by these is a long attenuated first-quarter moon-shaped bed. The ground is *Statice profusa*, and five clumps of fine examples of Malmaisons come up out of it. Valetta (deep blush), Old Blush, Duchess of Westminster and Princess of Wales are the sorts chosen. It is an original and pleasing group. Not far, again, from this, in the same tent (No. 4), is the imposing exhibit of Messrs. Cutbush and Son. Great mounds of The Queen (*terra-cotta*), Lady

of colour. In Tent No. 2 I found a regular feast of Carnations (Class 223). I have already referred to Mr. Englemann's lot. Adjoining it are Messrs. Allwood Brothers with their *La Rayonnante* (large deep yellow, *the yellow up to date*), *Geisha* (heliotrope) and *Wivelsfield Wonder*, all displayed in the famous Coldrum vases; they have an attractive group. So, too, have Mr. Dutton and Mr. C. Waters. Mr. Dutton's Mrs. A. F. Dutton is one of the best, if not the best, of all rose pinks. It is a sport from *White Perfection*; it has all the good points of that variety, and, in addition, is doubly as free. The centre of the bloom is a deep rose, which seems to get lighter and lighter towards the circumference. It is most attractive in a big bunch. Mr. Waters has two useful items in *Edith Waters* and *A. E. Manders*, the former a bright cerise and the latter an orange and pale carmine striped. Both should be seen. In Tent No. 6, at the River end, there is a fine stand of good, well-known varieties from Mr. H. Burnett. The season has been a trying one for him, and as a result we have a smaller group than he otherwise would have staged. His Mrs. Raphael is one of my special

PORTION OF MESSRS. LAXTON'S GROUP OF FRUIT. THE STRAWBERRY IS THE NEW KING GEORGE V.

Coventry (scarlet) and Queen Mary (maroon, border variety) are conspicuous. The old yellow border *Cecilia* is well shown. It is still about the best yellow for the garden.

Messrs. Stuart Low and Co., in Tent No. 5, have two good banks; one is entirely of Perpetuals and the other Malmaisons. In the latter, *Princess Juliana* is most conspicuous. The firm list it as an orange, but it is a very pale shade. I found, however, from the examples displayed that many blooms were more of a pink than anything else. The bizarre effect is rather nice. Another novelty is the crimson-purple Malmaison *Cleopatra*. It is a large bloom, which lasts well and is sweet-scented. Among this firm's Perpetuals, *Baroness de Brien* (a fanged deep shade), Mrs. Burnett (pink) and *Cinnabar* (the curious dusky scarlet) took my eye. Some people, I hear, say the latter is small. I do not think any the worse of it for that. Poor flowers, you might be of no use unless you were mighty giants! The same fault might be found with Mr. C. Turner's Ruby (Class 221), which is one of the sweetest flowers I put my nose to in the show. Its name well describes its shade

favoured. In the same tent, not very far away, we have Chrysanthemums and Carnations from Mr. W. Wells. His fine, white, sweet-scented *Wodenethe* looks well, and is certainly all that is claimed for it in sweetness.

Other exhibitors whose exhibits were not staged, or which I missed, were Lord Burnham, Mr. Bell of Guernsey and Mr. Fisher. No one who is interested in Carnations should miss a visit to the French Section. M. M. L. Ferard, Henri Vacherot and Rivoire and Son each have examples of Carnations according to French taste. It goes without saying that they are tastefully arranged, and the blooms are shown to their best advantage. A new race, *The Colosse*, has been raised by M. Vacherot, and he has fine examples of six of them in his group. *Jupiter* (red) and *Diane* (flesh) are the ones I liked best. But my space is now written up.

With many regrets I lay down my pen, for justice has not been done to half of the lovely flowers that are waiting to be admired. To slightly alter a now historic saying, "Go and see."

J. J.

TULIPS.

Since first the date of the "International" was fixed, Tulip-lovers have looked forward to the big show as being the chance of a lifetime to place some of its most attractive classes before the gardening public. Everyone expected to see Darwins, Cottages, Parrots and Florists "by the acre." It was just the week for them; the schedule committee frames most suitable classes which seem to be going "merry as a marriage bell," when, for some reason or another, Jupiter Pluvius withdrew his kindly help and left old Sol to warm us up at least two weeks before we wanted to be. Hence, no Tulips—not literally, but figuratively. Five persevering firms have staged groups; but oh! the labour and anxiety entailed. One lot spent two weeks of their life in a cellar. How the others passed their time I know not; but there they are, and I ask all who read these lines to make the best of them. They will give those who do not know them a faint idea of the beauty. Let me especially ask readers to look at Excelsior, Thérèse Schwartz, Moralis, The Dove, Louis XIV., Clara Butt and Primrose Beauty at Hogg and Robertson's; at Inglescombe Yellow at W. T. Ware's, Limited; at Melicette, Eric, Orange King, The Fawn, Emerald Gem and Rosamond at Dicksons' of Belfast; at the old double blue Flag, Quaintness, Hammer Hales, Bouton d'Or, Ellen Willmott, Perle Royal, Carnation and Pride of Inglescombe at Barr and Sons'; at Blue Amiable, Farncombe Sanders, King Harold, Edmée, Galatea and Glare of the Garden at R. H. Bath's; and at Cygnet, French Crown and Velvet King at Jeffries'. Should Mr. Bentley be exhibiting florist varieties, they must not be missed. All the Tulip exhibits will be found in Tent No. 6. JOSEPH JACOB.

SCIENCE AND EDUCATION TENT.

Though less showy than those of some of the other tents, the contents of the Science and Education Tent are not of less interest to all who grow plants. Three exhibits outside call for mention, all relating to fruit trees.

That from Reading College illustrates the growth and training of fruit trees from the youngest to their full development.

That from the Woburn Experimental Station illustrates particularly the various insect attacks to which fruits are subject, all in working order, also silver-leaf, while another portion of the same exhibit illustrates the effect of grass on the growth of trees.

The fruit trees from the John Innes Institution show the self sterility and self fertility in Plums.

Inside, Dr. Russell of Rothamsted illustrates in a striking manner the effect of soil sterilisation by various means on the subsequent growth of plants; and Dr. Brenchley, from the same station, shows water cultures, illustrating the effect of minute quantities of certain poisonous substances on stimulating the growth of plants.

Plant propagation is illustrated by the admirable exhibit of cuttings, &c., sent from the Royal Botanic Gardens at Edinburgh.

Professor Armstrong shows the effect minute quantities of certain stimulants have on plants.

Mr. H. J. Veitch shows a long series of grafts of plants belonging to one genus on stocks belonging to another, probably a larger collection than has ever before been got together. Mr. Daniel also has an interesting series of pictures in connection with grafting; while Professor Winkler shows the

extremely interesting graft hybrids between *Solanum nigrum* and the Tomato.

Professor Blackman illustrates by means of apparatus many facts in vegetable physiology.

Mr. Cheeseman of East Burnham shows a large number of seedlings of trees grown in water indoors.

Of exhibits dealing with plant diseases caused by fungi, there are a large number. Mr. Massee's beautiful drawings are especially noteworthy.

Mr. Horne illustrates Potato diseases by means of living specimens; Dr. Pethybridge, by means of preserved specimens; and Mr. G. T. Malthouse, the dreaded black scab of Potatoes.

Mr. Brooks shows the fungi which produce Plum rust in all their stages, and cultivations and specimens of *Stereum purpureum*, the cause of silver-leaf. The last-named disease Professor Percival also shows.

Mr. Salmon illustrates a number of fungoid diseases of fruit trees by means of living and preserved specimens; and the Board of Agriculture has maps showing the distribution and spread of some of the fungoid diseases, which it aims at

CUP PRESENTED BY HIS MAJESTY THE KING FOR THE BEST EXHIBIT IN THE SHOW, AND WON BY LIEUTENANT-COLONEL SIR G. L. HOLFORD, K.C.V.O., C.I.E., WITH THE ORCHIDS ILLUSTRATED ON PAGE 262.

repressing by legislation, and also by the distribution of literature relating to fruit-growing throughout the country.

Professor Theobald's exhibit shows a variety of the most injurious pests of cultivated plants; and Dr. MacDougall's series of figures also illustrate the same point. The other side of the table is illustrated by Dr. Berger's most interesting series of fungi which attack and destroy scale insects themselves parasitic on Oranges and so on.

In plant-breeding the most interesting exhibits are those of Messrs. Sutton, comparing old-fashioned with new varieties of vegetables, and the various species of *Solanum*.

Professor Bateson and Professor Keeble show *Tropæolums* and Chinese *Primulas* respectively, illustrating the numerous variations obtained in the second generation from the cross. Mr. Hurst illustrates the same thing with crosses of *Berberis Darwinii* and *B. empetrifolia*; and Mr. Cuthbertson

exhibits a most interesting series of paintings of Sweet Peas to show the parentage of some of these popular plants.

WINNERS OF CUPS AND MEDALS.

His Majesty the King's Cup, for the most meritorious exhibit in the show, was won by Lieutenant-Colonel Sir George Holford, K.C.V.O., C.I.E., with Orchids.

Queen Alexandra's cup for the best rock garden was won by Messrs. R. Wallace and Co.

His Grace the Duke of Portland's Cup, for the best exhibit in the show, Orchids excluded, was won by Messrs. J. Veitch and Sons with stove plants.

Sir Jeremiah Colman's Cup, for the second-best exhibit in the show (winner of the president's prize excluded), was won by Mr. G. Mount with Roses.

Lady Colman's Cup, for Carnations (see Class 216), was won by C. F. Raphael, Esq.

Sir Trevor Lawrence's Cup, for herbaceous plants (see Class 237), was won by Messrs. G. and A. Clark, Limited.

Mr. J. Gurney Fowler's Cup, for fruit (see Classes 349 and 351), was won by the Duke of Westminster.

Mr. N. N. Sherwood's Cup, for Sweet Peas (see Class 310), was won by Mr. C. W. Breadmore.

Mr. A. E. Speer's Cup, for annuals and biennials (see Class 236), was won by Messrs. S. Smith and Co.

The Worshipful Company of Gardeners' Cup, for Roses (see Class 190), was won by Messrs. George Paul and Son.

Messrs. J. J. Grullemans and Sons' Cup, for Hippeastrums (see Class 41), was won by Lieutenant-Colonel Sir G. L. Holford, K.C.V.O., C.I.E.

Messrs. Sander and Sons' Cup, for Orchids (see Class 65), was won by Mr. F. Menteith Ogilvie.

Messrs. Charlesworth and Co.'s Cup, for Orchids (see Class 65), was won by Sir Jeremiah Colman, Bart.

Messrs. Bunyard and Co.'s Cup, for fruit (see Class 350), was won by His Majesty the King.

Messrs. Dobbie and Co.'s Cup, for Sweet Peas (see Class 311), was won by Sir Randolph Baker, Bart.

The King's Acre Nursery Company's, Limited, Cup, for Roses (see Class 204), was won by Mr. J. Brown, J.P.

Messrs. George Paul and Son's Cup, for Roses (see Class 197), was won by Mr. J. Brown, J.P.

Messrs. Sutton and Sons' Cup, for vegetables (see Classes 394, 395, 396 and 397), was won by the Hon. Vicary Gibbs.

The National Dahlia Society's gold and silver medals (see Class 314), were won by Messrs. Stredwick.

The National Chrysanthemum Society's gold and silver medals (see Class 189A) were won by Messrs. W. Wells and Co.

The Perpetual Flowering Carnation Society's gold medal (see Class 223) was won by Mr. Bertie E. Bell.

The National Sweet Pea Society's one gold medal and two silver medals (see Classes 310, 311 and 312) were won by Sir Randolph Baker, Bart., Mr. W. E. Alsen and Mr. L. H. Hatting respectively.

*** Owing to the pressure on our space, and the fact that they were not staged until as late as possible, we are compelled to hold over the report of the vegetable exhibits and sundries until next week.*

THE ROSE GARDEN.

EARLY ROSES.

THE high perfection attained by our florists in the forcing of Roses has practically brought summer-time into winter and spring. To see Roses offered for sale in the streets in April was unheard of some thirty years ago; but only recently (in April) I was offered splendid long-stemmed Mme. Abel Chatenay Roses at three a penny!

Although this glut of spring Roses is very remarkable, it does not debar one from admiring and appreciating the first-comers outdoors. How we welcome the first bud of the old pink Monthly or of Gloire de Dijon, telling us that the glorious Rose season will soon be here. I have no doubt but that this season will be quoted in the future as one of extraordinary earliness. Many Roses had buds of quite large size upon them the first week in May, and Conrad F. Meyer was in bloom in a garden close by on May 8, while in my own garden the beautiful snowy white Blanc Double de Coubert, Rosa Hugonis and the common Monthly were also in bloom.

Some Hybrid Perpetuals that made fine long growths last year, and which were left unpruned this spring, were also showing colour at that date. To obtain some early Roses I would commend this plan; Cut out the old wood in autumn and leave the new wood almost full length, merely stopping the plants in September by pinching out the points. In spring do not prune. Of course, one runs a risk of injury by frost, but in sheltered gardens such plants often escape. Rosa sinica will soon be out on walls, and in the open, running upon tree stumps, its lovely hybrid, sinica Anemone, has its buds well advanced. Buds of that unique Rose Juliet are already larger than marbles, and clusters of buds upon Grüss an Teplitz and Hermosa that were sparsely pruned will soon be enlivening our gardens with their charming sprays. The dear little Scotch Roses are fast advancing, and it is always a delight to have them with us, not omitting the beautiful Yellow Scotch or Williams' Yellow. R. altaica is a gem and one of the loveliest of early Roses;

so also is R. hispida, a pale yellow single, the buds of which before they unfold resemble a bijou Isabella Sprout.

The Rugosa Roses are among our most valuable garden varieties for early flowering. Blanc Double de Coubert (previously mentioned) is grand, and a beautiful crimson is Mrs. A. Waterer, which is as fragrant as brilliant. A fine big bush of Lambert's Carmen is now covered with buds. It is a single of a very glowing purplish crimson colour, and one well worth growing. I have not touched it with knife or secateurs; evidently the correct treatment to ensure a good blooming.

Other beautiful early Roses to look after are Blairii No. 2, Thalia, Euphrosyne, Polyantha grandiflora, Dawson Rose, Jersey Beauty and the pretty little De Meaux or miniature Provence, Mme. Plantier, a well-flowered bush being like a huge snowball. Then there are some of the better-class Roses that flower quite early, such as Climbing Mrs. Grant, Mme. Alfred Carrière and Reine Olga de Wurtemberg, all helping to make our gardens redolent with fragrance and beauty. Our forefathers knew nothing of the pleasures we have to-day, for most of these early Roses were unknown to them, and we have

also the ever-delightful wichuraiana Roses, nearly as beautiful with their glistening foliage as when in bloom, enabling us to clothe unsightly objects with their luxuriant foliage or to form picturesque features wherever desired.

ROSA XANTHINA FLOWERING EARLY.

This beautiful gem was in bloom with me on May 13, just about a week later than Rosa Hugonis. For beauty of the individual flower it is far in front of R. Hugonis. The petals are larger, the flower is of a more lovely cupped form and the colour deeper—quite a rich shade of Daffodil yellow, paling a little to the edges of the petals. The true R. xanthina is rather rare; why I know not, because it is quite hardy, growing out in the open among the Penzance Briars quite unprotected in the winter. It is termed the yellow Abyssinian Rose, being a native of that country, and was, and even is now, catalogued by some as R. Eca; but according to M. Crepin, R. xanthina is the name given to the species by Lindley in 1820, whereas R. Eca was adopted by Dr. Aitchison in 1880. Another synonym is that of R. platyacantha. M. Crepin says that R. xanthina is grown in a double form in China. One would like to see this double form. It would be interesting to hybridise these species with, say, R. sinica Anemone, and perhaps with the wichuraianas. Who knows what developments we might obtain! If even we could obtain more shades of yellow among the Scotch Roses it would be an immense gain to our gardens. I am trying R. Hugonis upon some of the Hybrid Teas, and I shall do so with R. xanthina. P.

CALCEOLARIA VEITCHII, A NEW GREENHOUSE HYBRID WITH MILK WHITE FLOWERS. RAISED BY MESSRS. ROBERT VEITCH AND SONS OF EXETER BY CROSSING C. ALBA WITH C. GOLDEN GLORY, AND SHOWN BY THEM AT THE INTERNATIONAL EXHIBITION.

Carmine Pillar and Waltham Bride will soon make an effective colour mass in the garden, and these will be augmented by the gorgeous Penzance Briars, which should be in every garden—one or two of the sorts at least—for their delicious fragrance following a shower is so refreshing. Una, one of the loveliest of the Hybrid Briars, is always a welcome early Rose, and the unique-coloured Austrian Copper gains admirers every season.

The beautiful rambler Aglaia, if left unpruned, will be presently like a big golden ball, and its more erect-growing rival, Electra, is seen well in a large bed edged with Ruby Queen pegged down.

The species by Lindley in 1820, whereas R. Eca was adopted by Dr. Aitchison in 1880. Another synonym is that of R. platyacantha. M. Crepin says that R. xanthina is grown in a double form in China. One would like to see this double form. It would be interesting to hybridise these species with, say, R. sinica Anemone, and perhaps with the wichuraianas. Who knows what developments we might obtain! If even we could obtain more shades of yellow among the Scotch Roses it would be an immense gain to our gardens. I am trying R. Hugonis upon some of the Hybrid Teas, and I shall do so with R. xanthina.

CLIMBING ROSE HIAWATHA.*(See Coloured Cover.)*

This beautiful climbing Rose, a spray of which forms the coloured cover for this issue, has proved one of the most popular of recent introductions. It was raised by Mr. M. H. Walsh and first put into commerce in 1905, since when it has found its way into nearly every garden where Roses are grown. It has a vigorous trailing habit, and is one of the best Roses for a pillar, arch, pergola, weeping standard or screen. Although the flowers are single, they last in good condition for a considerable time, and the plant is not usually badly attacked by insect or fungoid pests. It is now obtainable from any good Rose nurseryman.

SWEET PEA NOTES.

At the "International."—At the time of writing these notes it has not been my pleasure to see

to the hosts of visitors from various parts of the universe who will be present. I hope that those who contribute to the exhibition will reap a rich reward in business as well as the reward that magnificent flowers which one has grown always bring to their possessors.

Watering.—Plants out of doors had not the happiest of times in April, and those who postponed the planting until as late as they dared have not lost, as indeed they never do in our peculiar climate. Right through the month named no rain that was worth measuring fell, and in the Southern Counties at any rate, if not in all, recourse was made to the use of the water-pot much earlier than one likes to have to do it. Although there was generally enough moisture down below, it was too deep to be of substantial advantage, and the top became as dry as we usually expect to see it at the middle of July. We all acknowledge the inestimable value of deep cultivation and incessant surface-stirring;

Disbudding.—This process will now be directed towards the removal of blossom as well as growth buds, and will be carried out in degrees varying widely according to the principal object of culture. Those who aim at the production of the biggest blossoms exclusively for purposes of exhibition will be most severe, while those who desire to gather a few bushels of beautiful, though smaller, flowers on shorter stems will be proportionately moderate in suppression. Many judgments at exhibitions decree that the stems shall be long, say, anything over a couple of feet, and that each shall carry any number of blossoms beyond four; but the home decorator knows full well that stems about twelve inches or fourteen inches long, with three or four flowers artistically set, will make up the most delightful vase in skilful hands.

Syringing.—That evening heavy syringing or hosing—the latter is, as a rule, the better of the two—is advantageous after hot days, and in gardens where there is considerable dust, cannot be doubted for one moment, and the wonder is that it is not more frequently done by amateurs. Its primary benefit may be the invigoration of the plants after an exhausting day; but it has the further, and by no means unimportant, merit of keeping down attacks of green flies and other pests. These enemies of the Sweet Pea and its cultivator do not like applications of cold water coming through a hose or a powerful syringe, and it is not generally necessary to have recourse to other means to ensure their extirpation.

HORACE J. WRIGHT.

TREES AND SHRUBS.**RHODODENDRON FOSTERIANUM.**

AMONG the many beautiful Rhododendrons that require the protection of a cool greenhouse, this superb hybrid is certainly one of the very finest yet raised.

It is the result of crossing *R. vitichinnum* with *R. Edgeworthii*, two beautiful species in themselves. *R. fosterianum* possesses the good qualities of forming a shrub of robust habit, with a disposition to flower freely, while an individual flower measures from 6 inches to 7 inches in diameter,

which is larger than any other of its section. The loose heads are from three to five flowered, pure white, with a yellowish blotch at the base of the lobes. They are also deliciously fragrant, a single truss being sufficient to scent a large house. This tender race of Rhododendrons is excellent for planting in the borders of a cool conservatory, when during the spring months the plants afford a grand display of blossom, and even during the rest of the year their foliage is very ornamental. Specimens may also be successfully grown in large pots or tubs. They are among the easiest of plants to manage, provided they are planted in a well-drained, light, peaty soil which is free from lime, as Rhododendrons will not succeed where lime is present in the soil or water; therefore rain-water should be used for watering in preference to any other.

W. T.

A FLOWERING SPRAY OF RHODODENDRON FOSTERIANUM.

many Sweet Peas approaching to the flowering stage, but those that I have seen gave grand promise of beauties to come. We grumble, as Englishmen necessarily must do to keep them in a satisfactory state of health and happiness, that the date is far too early for the Queen of Annuals; but we know all the time that our Breadmores, Alsens, Dobbies and many others are more than equal to the task of maintaining their own splendid reputations and that of their country as well. When the issue of THE GARDEN containing these notes is published, there will be such a display of Sweet Peas in the grounds of the Royal Hospital, Chelsea, as has never been brought together at a similar season of the year in any part of the world, and I shall be much surprised if that section of the "International" does not prove to be one of the most attractive of all

but they were never more forcibly demonstrated than this year, and anyone who has been sceptical on the subject hitherto will have no semblance of a doubt in the future. In any event, it is absolutely imperative that the plants shall not be permitted to stop advancing now, or the results will be more or less disappointing to the grower, whether he desires blooms for exhibition or for home cutting. See, therefore, that the soil is maintained pleasantly moist, and that the top inch or two inches is always like so much dust. When water is required, cut a shallow grip along each side of the lines a few inches away and repeatedly fill with water until enough has been given for the moment; this is infinitely preferable to pouring hard, cold main-water directly on to the bases of the stems of the plants.

GARDENING FOR BEGINNERS.

THE DOUBLE FLOWERED ARABIS.

ARABIS, Wall Cress, or Rock Cress—call it which we may—is a plant that every amateur should grow, both on account of its beauty and usefulness and for the ease with which it may be grown. The double white variety is a great improvement on the single forms, for not only does it create a better effect, but it continues to flower over a much longer period than the single forms. I can imagine no finer sight in the rock garden than a large mass of the double form of *Arabis albida* known as Snowdrift, a well-named variety that flowers in great profusion, and which is the best of all companion plants to the *Alyssum* and *Aubrietia*.

In propagating the double varieties one has to have recourse to cuttings, and these are best taken in late May or early June after the flowering period has passed its best. Cuttings should be inserted in soil of a sandy nature in a partially-shaded border. The cuttings root quite easily, and in an incredibly short space of time every cutting will have made a tuft

of healthy green foliage. By the following spring one will be rewarded with good-sized flowering clumps. The double *Arabis* deserves to be more widely cultivated than it is. Not only is it so well adapted for clothing rockwork, as is seen in the above illustration, but it is also an admirable subject for spring bedding when associated with May-flowering Tulips and Forget-me-nots. Moreover, it might be used with advantage more freely for covering the ground

THE DOUBLE-FLOWERED ARABIS IN THE ROCK GARDEN.

between groups of tall-growing plants. As a carpet in a bed of standard Roses it looks very well, and even when not in flower its light green foliage is attractive.

BASKET PLANTS FOR GREENHOUSES.

A FEW baskets neatly filled with plants, both flowering and foliage, suspended from the roof of a greenhouse or conservatory give to the

structure a thoroughly finished appearance. If, however, the baskets are badly filled or allowed to become ragged in appearance, they will be an eyesore. Caked moss is sometimes used for lining the baskets, but I do not favour it. I have found from experience that such moss requires most careful treatment, and even then it dies. Of course, the crust keeps the soil from trickling through, but it does not look very attractive. The ordinary loose-growing moss is the best. It must be carefully picked over, all but the live portion being rejected. Suspend the basket in a shed at a convenient height; then commence at the bottom and pack a substantial layer of the moss against the wires, at the same time putting in the compost until the basket is three parts filled. At this stage the plants should be put in and the remaining soil placed around their roots. The moss must come flush with the top of the basket, but the soil should be nearly two inches lower to allow of the necessary watering from time to time, although watering by immersion is often desirable. If the moss is syringed regularly twice every day, it will not only retain its freshness, but grow also. It is a mistake to use a very fine soil in baskets. Fibrous loam with the finest portion sifted out and some half-rotted leaf-soil and a small quantity of well-rotted manure will form a very good and lasting compost.

Suitable Plants.—For the centre of the basket, Fuchsias, *Abutilons*, *Heliotrope*, *Lantanas* and Ivy-leaved *Pelargoniums* if the latter are trained to a stake or the wires of the basket. Ivy-leaved *Pelargonium Mme. Crousse* and blue *Lobelia* look well; so also do baskets of *Achimenes*, *Coleuses*, *Isolepis gracilis*, *Tradescantias* and *Panicum variegatum* are serviceable plants, the last-named two for growing out through the moss at the sides of the baskets. B.

GARDENING OF THE WEEK.

FOR SOUTHERN GARDENS.

Plants Under Glass.

Campanula pyramidalis.—Sow seeds now of this handsome and useful greenhouse plant for producing spikes next summer of both the blue and white varieties.

Canterbury Bells.—These make charming plants for the cool greenhouse to flower next spring, and may be sown in a pot or pan and afterwards pricked out and grown on, or young plants can be lifted and potted from the open ground in the autumn.

Calceolaria Clibranii.—For decorative purposes, both for the conservatory and indoors, this plant is admirably adapted, as the branching habit is most pleasing. The plant is easily raised from seed or cuttings, and if potted on as becomes necessary, make fine specimens.

Gloxinias.—While these are flowering, their season may be much prolonged by giving the plants a warm greenhouse temperature and drier conditions than those afforded during their season of growth, and stopping the use of stimulants.

Primula kewensis.—Seed may be sown now of this pretty and useful hybrid, or the plants increased by division. Throughout the summer months give the plants shade from sun and plenty of air, and as the pots fill with roots, manure-water, properly diluted, will be beneficial.

Fruits Under Glass.

Earliest Peaches and Nectarines.—As the trees of fruit ripen, increase the amount of ventilation and leave air on the top of the house at night. Discontinue syringing the trees, but damp down the paths and borders at least twice daily when the weather is bright. Great care should be exercised in gathering the fruits, as these are easily bruised. The fruits should never be squeezed to ascertain if they are ripe, but carefully lifted upwards, and if ready they will easily detach. If the trees are gone over daily, very few fruits will drop.

Early Cherries.—When the fruits have been gathered from the trees, whether pot or permanent, give the trees thorough syringings again, as oftentimes the absence of such while the fruits are ripening encourages red spider. If the trees are badly infested, the additional use of an insecticide will be found doubly beneficial. If the borders are dry, give a good soaking. Admit abundance of air.

The Shrubbery.

Lilacs.—A collection of these at this season is a grand addition to the shrubberies, and young plants well set with buds may be conveniently lifted and potted in the autumn for forcing under glass. A few of the best would include Charles N., single blue; Marie Legrave, large single white; Souvenir de L. Spath, a fine variety, large trusses of single dark red flowers; Alphonse Lavallée; President Loubet, early, rose purple, double-flowered, handsome truss; and Charles Joly, dark red.

Rubus deliciosus.—Unlike many of the species, this, whether grown as a bush or trained on a wall or pillar, is worth including. Commonly known as the Rocky Mountain Bramble, this shrub produces large white single flowers in great profusion.

The Kitchen Garden.

Tomatoes.—In the majority of places, and especially where the further protection of a wall or fence is afforded, it should be quite safe to plant out of doors after these lines appear in print. Oftentimes a low wall can be well utilised by training the plants in a sloping manner. Avoid the use of manures at the root, give a good watering in after planting, and apply a light mulch of strawy material.

Ridge Cucumbers.—These may be planted out towards the end of the month, after having first prepared a bed of long litter and leaves on which has been placed some fairly good soil made in the shape of a ridge and about a foot deep. Plant a yard apart, and keep the plants damped frequently in hot weather. Last season suited these well. In the event of a sunless summer, a cold frame will ensure a supply. King of the Ridge and Stockwood are both good varieties.

Runner Beans.—Where the sowing in pots as was recommended is not permissible, the seed may be sown in the trenches about the end of this month. Well prepare the latter and take out as much of the natural soil as possible, filling in with some well-decayed manure, covering with enough soil to leave a depression for watering. Sow the seeds in a double row and cover with 2 inches of the finest soil. The seeds will not need to be placed less than 6 inches apart. Place a ring of cinder-ashes round each, and, when germinated, dust occasionally in the early mornings with soot.

Parsley.—Keep the hoe going among this crop. Dust occasionally with fresh soot, which not only stimulates the growth of this plant, but imparts that dark green colour and prevents slugs attacking the plants.

The Flower Garden.

Summer Bedding.—The time has almost arrived when this will be in full swing. As quickly as possible remove the plants that have contributed to the spring display, saving any that are wanted for propagation. Well dig over the beds, first giving a dressing of decayed manure. Make a commencement with all the hardiest subjects, and where standards are employed, these can be planted and staked, the groundwork being planted afterwards. The more tender subjects, such as Mesembryanthemum, Ageratum, Begonias, Iresine, Alternanthera and Salvias, should be placed out last.

Dahlias.—These may be planted out when thoroughly hardened off, into well-prepared, heavily-manured ground. For the back of the herbaceous border, where space permits, these provide a display of flower when many things are past. For cutting in the autumn the Cactus and Pompon varieties are well suited. Only those varieties with strong supporting stalks should be grown for decorative purposes.

E. BECKETT, V.M.H.

Aldenham House Gardens, Elstree, Herts.

FOR NORTHERN GARDENS.

The Fruit Garden.

Gooseberries.—It is usually important to thin overloaded bushes, using the thinnings for tarts and jelly-making. Industry is the first that needs attention. A look-out for caterpillars must be kept.

Strawberries.—Delay no longer to place straw or litter between the rows of the main cropping and late varieties, in the first place thoroughly hoeing the ground and picking out weeds from among the plants. Young plantations need not be strawed, but runners as they push should be removed. This is quickly performed at this stage, requiring a much longer time if the runners are permitted to extend a few feet before cutting them off.

Hardy Shrubs.

Rosemary.—This succeeds on low walls, and now that the flowers are past it should be closely trimmed with a pair of hedge shears. A constant supply of young plants, either from seeds or cuttings, should be kept up to fill blanks, and these are best grown in pots so that they can be planted at any time.

Lilacs.—These are very early this year, and immediately the flowers are past, the bushes should be examined and pruned as required. Bought plants are usually worked on Privet, which throws suckers; but a stock on their own roots is easy to produce by striking cuttings of the young soft shoots at this time in an ordinary propagating-case.

The Vegetable Garden.

Salsify and Scorzonera.—In our light soil these roots run to flower if sown earlier. The first-named is seeded very thinly, and needs no thinning of the seedlings; the latter needs more space, and the plants should be a few inches apart.

Peas.—A large breadth of Autocrat, The Gladstone, or Sharpe's Queen should be sown at once in trenches if at all convenient. Should the soil be in the least inclined to dryness, thoroughly soak the ground after the trenches have been

prepared and cover the seeds with the unmoistened soil, which should be finely pulverised, to act as a mulch. It is a good plan to put supports to the rows at once, the plants growing so rapidly once they are above ground that it too often happens that staking is delayed, to the injury of the crop.

General Work.—The thinning of seedlings, e.g., Beet, Parsnips and Carrots, will require attention, and the application of surface-dressings of soot, pigeon and poultry manure and superphosphate made to these and other crops. Beans, Potatoes, Cabbages and Cauliflowers will need earth drawn to their stems and the soil loosened between the rows. Transplanted Onions also should have the soil deeply stirred between the rows, and, if needed, surface-dressed with a stimulating manure.

Plants Under Glass.

Cinerarias.—A few seeds may be sown to produce flowering plants in December. They germinate freely in a cool structure.

Primulas.—Old plants of *kewensis*, *verticillata*, *Forbesii* and *floribunda* may be divided into pieces of a suitable size, placed in small pots, and grown on meanwhile in cold frames. All succeed in a simple compost of loam, leaf-soil and enough coarse sand to ensure porosity.

Malmaison Carnations.—These must be afforded a thick shade in order to secure depth of colour in the blooms, which will shortly expand. Besides thinning the flower-buds it is profitable to reduce the number of young shoots to about half-a-dozen on each young plant, or on each stem of older plants, which results in stronger layers if they are wanted for increase or renewal of stock, and better growths if for bloom the succeeding year.

Begonia Gloire de Lorraine.—Cuttings were very late this year, but the young material should now be progressing rapidly. Much can be done to hasten growth by shifting the plants as they become ready, and not letting them stand unattended for a week or longer. A high temperature with much moisture also conduces to rapid growth. Vaporise occasionally as a protection against mite.

Palms.—The glass in the structure in which these are growing should be heavily obscured, and the atmosphere of the house kept very moist and warm. The plants themselves require much water at the root, and when well established in pots they enjoy a considerable amount of manure dissolved in the water, these conditions resulting in dark green foliage.

The Flower Garden.

Geraniums.—In most localities these still popular plants may be planted into the beds they are to adorn. If the soil is dry, moisten it the day previous to planting, the plants themselves being nicely moistened before starting operations. A slight sprinkling of superphosphate over the surface is beneficial, but it should be very slight. Geraniums are more floriferous if the ground is firm; therefore see that every plant has the soil made quite firm about it as planting proceeds.

Other Plants.—*Calceolaria amplexicaulis*, *Verbenas*, *Lobelia*, *Ageratums* and *Petunias* are other plants that may be gone on with, so arranging that those turned out of pots may be planted in the early part of the day, and those from boxes after 3 p.m., thus giving them several hours in the soil before the sun touches them. *Salvia fulgens*, *Begonias*, *Fuchsias* and *Heliotropes* are examples of plants that it would be unwise to plant out before June.

China Asters.—These, though small, are quite ready to transplant. Ours are lifted from the seed-bed in cold frames, the roots drawn through a mixture of soil and water and planted forthwith. A large number are set apart for filling gaps in late autumn, and are now dibbled into lines a foot apart each way. Some of the singles are invaluable for the latter purpose, both because of their intrinsic beauty and because they flower so late.

Biennials.—*Canterbury Bells*, *Wallflowers*, *Sweet Williams*, &c., sown six weeks ago should be transplanted while yet small, leaving slow-growing things like *Campanula pyramidalis* some time longer. The ground selected to grow them in should be very fertile in the upper 6 inches and in a nice friable condition. Once planted and watered, as a rule, an occasional hoeing is all they need afterwards.

R. P. BROTHERTON,
Tyningham, Preslonskirk, N.B.

THE KITCHEN GARDEN.

THE CULTURE OF LATE PEAS.

WITH light soils resting on gravel, for very late dishes I have found it best to sow what may be termed the dwarf earlies, sown in rows not far apart. No staking was done, but the bare soil between the rows in hot or dry weather was mulched with short manure. This was of great assistance in keeping the roots moist, otherwise the crops were a failure.

There need be no waste of land, as it is an easy matter to crop between the rows of Peas. At times the land is too heavy, and if this is so, the cultivator has a splendid opportunity to ameliorate and lighten it. Especially is this the case in most gardens of any size, as with considerable quantities of garden refuse burnt frequently and placed in heaps, this makes splendid material for adding to heavy soil, as it lightens and improves the texture. There are other aids, such as fine old mortar rubble, wood-ashes, broken chalk or lime used at the trenching. The work should be done when the land is fairly dry and not waterlogged. In such land spent manure from Mushroom-beds, old leaf-soil, or anything that lightens and improves, is beneficial.

No doubt the greatest difficulty exists when the soil is very shallow, resting on gravel, and the summer is hot and dry. In the preparation of the land I advise additions of heavy soil, but this in some instances is not always practicable, and other means must be adopted. I would advise growing all the late varieties, if of a medium height, or tall kinds in trenches—I mean varieties averaging from 3 feet to 6 feet—as the soil in the trenches can be made good by removal of the poorer material.

If the Peas are from 3 feet to 5 feet in height, the space should be at least that distance apart between the trenches. If taller, the space should be more, and a liberal amount of good manure worked in the soil at the bottom of the trench, placing over this the top spit or surface soil for sowing the seed.

Sowing.—This should be done carefully. In no case allow the seeds to touch each other. The taller the variety, give more room. Sow in broad-bottomed drills, not pointed. Last summer I noted that dwarf Peas of the Early Giant type allowed to lie on the soil gave a splendid return, as the haulm in a great measure protected the plants from drought, though, of course, there was a little more trouble in gathering the crop. I have not referred to dates for sowing or length of seasons, and these must be governed by the grower according to the time the crop is required and for how long. For instance, for September and early October, or, say, August and September, I should advise the late Marrowfat section, such as those of the Matchless Marrowfat type sown in May and June, and in well-prepared soil early in July. These will give a succession of crops from August to the end of October. In the North I have with very little difficulty had splendid crops till the end of November in a mild autumn. For certain soils I would advise sowing what are termed the first earlies—I mean soil of a poor nature on gravel or chalk—and to liberally manure. Of course, here the rows are much closer together, and due attention should be paid to shade and moisture. Given a good holding soil, there is no difficulty in growing the tallest varieties

for late supplies, such as Ne Plus Ultra, Selected, Gladstone, Late Queen, Alderman and others; but sow thinly and give ample room between the rows. In dry weather mulch between the rows with long litter or spent manure of any kind. This, well watered once or twice a week, will keep the roots healthy and do more good than overhead waterings of a light nature at irregular periods; and if it is impossible to mulch the surface soil all over, much assistance may be afforded by mulching each side of the rows and growing in deep drills or shallow trenches. G. WYTHES.

THE EDITOR'S TABLE.

Paulownia imperialis from Sussex.—Mr. P. Sutherland sends from Sussex flowering sprays of this beautiful tree. As stated in our issue for May 18, it has flowered in several places this year. Mr. Sutherland writes: "I am sending you flowers of *Paulownia imperialis*. The tree is about twenty years old and has just flowered here in Sussex for the first time."

Spring Flowers from Ireland.—The Rev. W. W. Fleming, Coolfin, Portlao, County Waterford, sends a beautiful collection of spring flowers. The Iris and Tritonia were particularly interesting. Mr. Fleming writes: "I am sending for the Editor's table some flowers from my garden. Tree Pæony, two varieties, five others I have being out of bloom, also two herbaceous Pæonies, old double crimson and another. *Viburnum plicatum*, not full size yet or pure white colour, but with that light lemon shade and pink suffusion noticeable before the flowers have attained their full size. Tulips Erguste, Isabella, Fairy Queen, Mr. F. Sanders and Margaret. The finest of the Darwins, Pride of Haarlem, is over. *Vitis Coignetie*, just to show the lovely bronze of the young leaf. *Fabiana imbricata* in full bloom. *Magnolia verbanensis*, nearly over, very like *soulangiana*, but, I think, better. *Rhododendrons* Doncaster and Pink Pearl, too well known to require a word of praise. *Tritonia crocata*, salmon shade. Iris *florentinus*, just beginning to bloom. Two blooms of *double Lily of the Valley*; I think an uncommon plant. Last, but I think not least, some blooms of *Azalea mollis*, of which I have a large bed with over ninety seedlings raised by myself, all in full bloom this year. Although there were many different shades, none of the colours seemed to fight or disagree with the others. There was perfect harmony and delightful contrast."

Rose Foliage from Dolgelly.—Mr. C. L. Cox, Tanllan, Dolgelly, sends some beautiful Rose foliage, and we have never seen better. This year the foliage of most trees and shrubs is particularly large and handsome, the result undoubtedly of the ripening effect of last summer and the copious rainfall of the last winter and early spring. Which Rose in cultivation possesses the largest leaf would be difficult to say, as much depends upon cultivation and pruning. Many of the Hybrid Perpetuals have immense leaves as one year old plants, but we know of none larger than those of the *Gloire de Chedane Guinoisseau* sent by our correspondent, although *Etienne Levet* and its sport, *Duke of Fife*, will yield very handsome foliage; so also will *Mme. Isaac Pereire*. Some of the Hybrid Teas are particularly superb in this way, *Dr. O'Donel Browne*, *Marquise de Sinety* and *Joseph Hill* being very remarkable, and we notice you say the first-named is very fine with you. Standard Roses when pruned fairly hard

will certainly yield the handsomest foliage, and, providing good growers are selected, a Rose is seen to great advantage grown in that form. One must not overlook the fact, however, that there is such a thing as having grand foliage at the expense of good bloom. Where nitrogenous manures are used in a too large proportion, foliage is always fine and abundant; but unless the phosphates are in proper proportion, bloom will be much inferior. We cannot agree with our correspondent's suggestion that yellow, mauve and white colours should not appear in the summer, for by so doing we should exclude numbers of the loveliest Roses, to say nothing of other flowers. There is something very soothing about yellow and white shades, but garish reds and scarlets upon a hot day are not pleasant to all. Colour-schemes may be all very well with perennial and annual plants, but we think Rose-lovers would miss much pleasure if they adopted it to any slavish extent. Mr. Cox writes as follows: "This year the foliage on my Roses is particularly large and plentiful. I enclose a few specimens for your inspection and an ordinary Rose leaf and Strawberry leaf for you to compare the sizes with. I should like to know which Rose in cultivation is supposed to have the largest leaves, if you can tell me. The Roses in my garden which at present have the finest foliage are the following: Mrs. Isabelle Milner, Mme. Jules Gravereaux, Lady Waterlow, Pharisæer, General Macarthur, Mrs. Ben Cant, Hugo Roiser, Melanie Soupert, Mine. Jules Grolez, Lady Ursula, Dr. O'Donel Browne, La France de '89, Souv. de S. A. Prince and Walter Speed, all of which are in splendid condition, with dense masses of leaves of beautiful colour and texture, and full of buds just breaking. Most of them are standards, the only form of Rose plant I really like. These I have on the edges of lawns, with *Violas* in a circle at the base of each tree. My climbing Roses are on old Apple trees roped together and Clematises of different shades planted with them, so that they all scramble up together. There is no more effective colouring than pink and blue in a garden, to my mind, unless it be yellow, mauve and white in the spring; but the latter colours should not come forward again in a garden until the autumn, I think, and white should at all times be avoided as much as possible."

NEW AND RARE PLANTS.

FIRST-CLASS CERTIFICATE.

Cymbidium woodhamsianum Fowler's Variety.—A showy variety with amber-coloured petals and sepals. The lip is of a paler hue, tipped with chocolate. Parentage: *C. lowianum* × *C. eburneo-lowianum*. Shown by J. Gurney Fowler, Esq.

AWARDS OF MERIT.

Lælio-Cattleya Apollo.—A truly beautiful variety raised from *Cattleya Schröderæ* × *Lælio-Cattleya warnhamense*. The pale orange-coloured petals harmonise with the lovely mauve-tinted lip. Shown by C. J. Lucas, Esq.

Tropæolum albidiflorum.—A frail-growing climber or twiner having glaucous three to five parted leaves, the leaflets linear and half an inch or more in length. The flowers, which are pinky white, with orange yellow base, are nearly erect, open funnel-shaped and 1½ inches long. A pretty and distinct species. Exhibited by Miss Willmott, V.M.H., Warley Place, Essex.

Petunia Brown's Purple (Strain).—The award in this instance was given to the strain, the exhibited examples betraying slight variations of colour, which is of an intense royal purple. Should the variety come true from seed, or nearly so, it would prove of much value for window-boxes and the like. The flowers are single and of large size. Exhibited by Messrs. W. and J. Brown, Peterborough and Stamford.

Phyllocactus Coopermanni (P. Ackermannii major × P. Cooperi).—A variety of huge proportions and of bronzy scarlet colouring, the outer sepals shading to a dull brick red. It is a very handsome form.

Cereus amecænsis.—So far as we remember, no species of this genus has been honoured by an award for many years, a fact in measure due perhaps to the fugitive character of the flowers. That now shown had large and handsome flowers of spotless purity, which issue freely from the sharply-angled, erect-growing stems or branches of which this species is composed. These stem-growths as exhibited were several feet in length, some of the expanded flowers appearing low down, though several other almost fully-grown flower-buds appeared near the summit of the stem. These two excellent novelties were shown by Mr. A. Worsley, Isleworth.

The foregoing were shown before the Royal Horticultural Society at the meeting held on May 14.

ANSWERS TO CORRESPONDENTS.

RULES FOR CORRESPONDENTS.

QUESTIONS AND ANSWERS.—The Editor intends to make THE GARDEN helpful to all readers who desire assistance, no matter what the branch of gardening may be, and with that object will make a special feature of the "Answers to Correspondents" columns. All communications should be clearly and concisely written on one side of the paper only, and addressed to the EDITOR OF THE GARDEN, 20, Tavistock Street, Covent Garden, London, W.C. The name and address of the sender are required in addition to any designation he may desire to be used in the paper. When more than one query is sent, each should be on a separate piece of paper. Plants for naming should be clearly numbered and securely packed in damp grass or moss, not cotton-wool, and flowering shoots, where possible, should be sent. It is useless to send small scraps that are not characteristic of the plant. Letters on business should be sent to the PUBLISHER.

FLOWER GARDEN.

DELPHINIUM LEAVES INJURED (Churchill).—The Delphinium leaves have the appearance of having been injured by cold winds or frost. No fungus or insect is present to account for the blackening.

WALLFLOWERS FAILING (Enquirer).—The plants present the appearance of having been attacked by the fungus known as rot-mould, the simplest remedy for which is to lift and burn, soil and all, and avoid planting these and Stocks in the same ground for some time.

NARCISSUS DISEASED (A. E.).—There is a slight attack on the foliage of the Narcissus of the fungus Ramularia mallembricosa, and spraying with potassium permanganate will, no doubt, check the spread of this fungus. The main thing, however, that requires attention is the exhaustion of the soil, or, rather, the too close packing of the young bulbs which have formed since the plantation was made ten years ago. In dry seasons the supply of water is sure to be somewhat limited, and there are tremendous demands upon it when the bulbs are packed so tightly as these are in the present case. It is, therefore, likely that the leaves will suffer from want of water.

TREATMENT OF FLOWER-BED (H. D. R.).—The most profuse-flowering plants we know are Ivy-leaved Pelargoniums in pink and red shades; Ageratum, with a foot-wide border of white Violets; Heliotrope, similarly treated, or white, crimson, scarlet, pink and orange tuberous Begonias. Say, for example, you arranged a yard-wide centre of white Begonias, and set the remaining shades equally in triangular outline around. A simple and pretty bed would be one of Summer Cypress (Kochia) in the centre, pink Ivy-leaved Pelargoniums around, save for a foot-wide margin, to be finally planted with white Violets. In this arrangement the Pelargoniums would first require to be

pegged down to cover the soil, subsequently allowing the plants freedom of growth and flowering. The Heliotrope alone makes a fine bed, and the flowering is continuous, and where fragrance is cherished it is one of the best. The thing to avoid is too many plants of undecided colours.

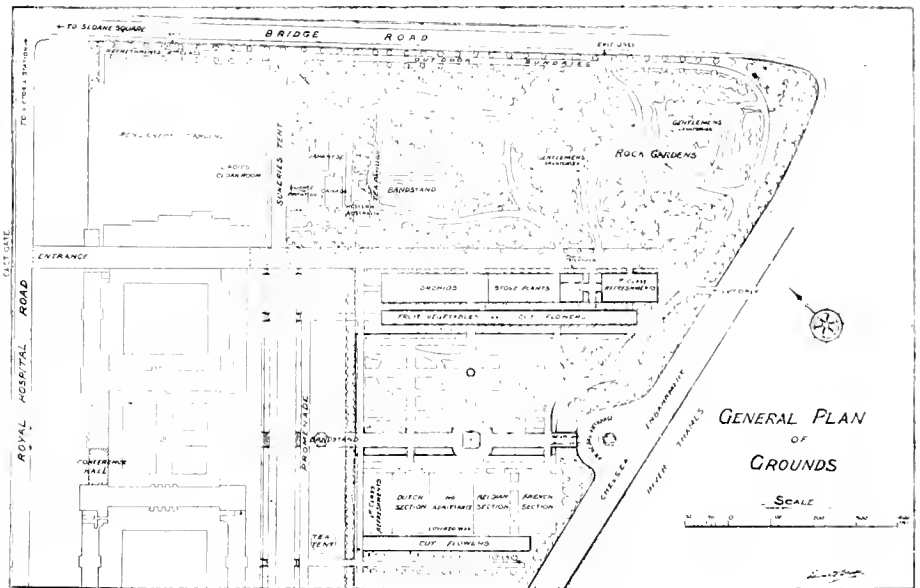

TULIPS DISEASED (Denbury).—The Tulips are attacked by the well-known Tulip fungus Sclerotinia parasitica. The spores of this appear to attack plants most easily when the latter have been weakened by frost. No cure is known, but the fungus forms black, hard masses, called sclerotia, by which it passes over the winter. It would be well to remove all the decaying leaves as soon and as completely as possible, dig up the bulbs and clean them thoroughly of earth, and search for these little black resting bodies, which vary from the size of a pin's head to that of a Pea, if it is desired to plant them again this season. A new site should be chosen.

SERIES OF PLANTS FOR TUBS (M. D.).—After your Rhododendron is past you may for a time depend upon tender subjects, such as flowering Cannas, Fuchsias and the common Hydrangea. Then in August a succession can be kept up by the creamy white flowered Ilydrangea paniculata grandiflora and the lavender blue Perowskia atripliciflora. After these come the blue-flowered Ceanothus Gloire de Plantières and the pink-flowered Ceanothus Marie Simon. These, with the purple Veronica speciosa, will last well towards the end of September, to be followed by Desmodium penduliflorum, a pretty Pea-flowered shrub with purple blossoms. After this is over we can recommend a berried Aucuba, which will last until the Laurustinus and Winter Jasmine come in. This Jasmine, though usually grown as a climber, may also be treated as a loose bush. Besides the above-named shrubs, some herbaceous

reclothe the branches, whereas now a considerable amount of new wood has already been made. Clip it back as hard as possible, so that the main branches are kept close to the wall.

PROPAGATING HARDY HEATH (B. L.).—We are afraid that you will not be able to purchase seeds of Erica Veitchii. Why not propagate it from cuttings? Very satisfactory results may be obtained by taking cuttings in July and August and inserting them in pots of sandy peat made very firm. Insert the cuttings firmly and stand in a close and slightly warm frame, or case, until rooted. If a bell-glass is placed over each pot of cuttings in the case, roots will be formed more quickly than if the cuttings are allowed a greater amount of air. Keep the young plants in a cold frame or sheltered border in April. Seeds of conifers may be obtained from Messrs. Dicksons, Limited, Chester; Messrs. Little and Ballantyne, Carlisle; and Messrs. Wiseman, Forbes, N.B.

TIMES FOR TAKING CUTTINGS (E. P. K.).—Cuttings of Forsythia may be inserted at once in a cold frame or a slight hot-bed. Cuttings of Rambler Roses, Hybrid Tea Roses, Ceanothus and Cotoneaster should be taken during July and August, and be inserted in pots of sandy soil in a close and slightly warm frame. Cistus cuttings may be taken at the same time, and either be placed in gentle heat or in a cold frame. Under either condition, however, they must not be allowed to become very wet. Brooms, as a whole, are better increased by means of seeds than by cuttings. Cuttings taken during July and August, however, can be noted in a cold frame. Staphylea and Cotoneaster cuttings may be rooted in gentle heat during July and August. Cuttings of Aubrietia, Alyssum and Pinks ought to be inserted at once, either in a cool shaded

GROUND PLAN OF THE ROYAL INTERNATIONAL EXHIBITION.

subjects may be grown, as Michaelmas Daisies do well in this way, and are especially valuable in the autumn, while last season we saw a pot specimen of the warm terra-cotta-coloured Heleium Riverton Gem, which flowered throughout the month of August and well on into September.

DISEASE AMONG ANEMONES (N. G. H.).—The fungus attacking the Anemones has hitherto been known in this country as *Æcidium punctatum*, and now as a form of the Plum rust, *Puccinia pruni*. So far as we are aware, it is likely to attack any form of Anemone coronaria. The spores formed on the Plum leaves (teliospores) in late summer, and falling to the ground with them in autumn, are the source of infection of the Anemone in the spring. It differs from *Æcidium leucosporum*, which occurs on the Wood Anemone, and the alternate host of the other, if it has one, is not known. If the Anemones are so poor, it would be well to destroy them. Probably spraying in spring with a rose red solution of potassium permanganate, or with ammoniacal copper carbonate, would check the attack on the Anemone, while affected Plums may with advantage be sprayed with Bordeaux mixture.

TREES AND SHRUBS.

PRUNING HOLIES (E. P. K.).—Hollies may be pruned any time between the present and the end of August; the earlier the better, however. Do not clip them in a formal manner, but reduce the overgrown parts by drawing some of the longer shoots out. These remarks do not, of course, apply to hedges and formally-grown trees. It is usually as well to keep the lower branches free from the ground. Ivy should be clipped at once; in fact, it is already a little late. April is a good month, for it may then be clipped severely, and new leaves will appear almost at once to

border out of doors, or, better still, in a cold frame. Rosemary and Lavender cuttings may be inserted in a cold frame during August, or earlier if you like. Pansies may be rooted any time between the present and September, either in a bed out of doors or in a cold frame. Winter Sweet is very difficult to root from cuttings, and you would do better to layer some of the lower branches at once. Almond trees are usually grafted or budded upon Plum stocks. You will not do much good with them from cuttings. Some of the subjects mentioned above may be rooted in an open border, but the results are usually less satisfactory than when a frame is used.

ROSE GARDEN.

DESTROYING RED RUST ON ROSES (A. M. G.).—Red rust, or orange fungus, can more readily be prevented another season if all leaves that are attacked be gathered up in autumn and burned. If this were thoroughly done, no infection would take place the following season. It is well to spray the bushes as soon as the foliage appears in the spring with sulphide of potassium, 1 ounce to two gallons of water, and as the foliage strengthens a stronger dose may be used. As your Scotch Briars are by this time well developed, you can safely use the stronger solution. This is best applied with a sprayer, one known as the "Alpha" being an excellent article. If Rose-growers would use a sprayer early enough and continue spraying throughout the early stages of growth, far less trouble from insect and fungoid pests would be experienced; but it is almost hopeless to attempt a cure when the attack has been allowed to gain the ascendancy. To trap field-mice we have found narrow-necked pickle jars half filled with water and sunk in the ground up to their rims to be very good. There are also some excellent poisons on the market for destroying mice and moles, for which we would refer you to our advertising columns.

EDITORIAL NOTICES.

Every department of horticulture is represented in THE GARDEN, and the Editor invites readers to send in questions relating to matters upon which they wish expert advice.

The Editor welcomes photographs, articles and notes, but he will not be responsible for their safe return. All reasonable care, however, will be taken, and where stamps are enclosed, he will endeavour to return non-accepted contributions.

As regards photographs, if payment be desired, the Editor asks that the price required for reproduction be plainly stated. It must be distinctly understood that only the actual photographer or owner of the copyright will be treated with

The Editor will not be responsible for the return of artistic or literary contributions which he may not be able to use, and the receipt of a proof must not be taken as evidence that an article is accepted. Publication in THE GARDEN will alone be recognised as acceptance.

Offices: 20, Tavistock Street, Covent Garden, W.C.

NOTES OF THE WEEK.

A Correction.—In our issue for last week the names of two of the directors of the Royal International Horticultural Exhibition, on page 254, were placed under the wrong portraits, due to the transposition of the blocks. These were Mr. A. C. Jackman and Mr. Hubert J. Greenwood, J.P.

Cornus florida rubra.—This is a handsome free-flowering Dogwood with creamy white flowers surrounded by red bracts, which makes it very interesting. In the autumn they turn a deep crimson and last a considerable time on the tree. *Cornus Nuttallii* has been grand this season.

The Labrador Tea (*Ledum latifolium*) is a very pretty plant and in cool spots will bloom profusely. It grows from 2 feet to 3 feet in height. The flowers are white and produced in terminal corymbs. It is a perfectly hardy, neat-growing shrub and an old one, but is seldom seen now. It succeeds best in cool, peaty soil.

Enkianthus campanulatus.—This is a rare deciduous Japanese shrub, growing about three feet to four feet. When it is in flower it is very beautiful, as it bears clusters of dark red, waxy, bell-shaped flowers, and in the autumn the small foliage turns a beautiful red. This is an excellent plant for choice positions and as dot plants in the alpine shrubbery. *Enkianthus japonica* bears white flowers with scarlet foliage in the autumn.

A State Diploma for Horticulture.—An important statement was made by Mr. Walter Runciman, M.P., in his speech at the jury's luncheon at the Royal International Horticultural Exhibition. The Minister for Agriculture advocated (and practically promised) a State diploma for horticulture in this country, a hint that was heartily approved. The necessity for such a diploma has long been felt, and never more so than at the present time.

The Snowdrop Tree (*Halesia tetraptera*).—This has been in perfect bloom, and is a tree that cannot fail to bring forth admiration. The flowers are snow white, drooping on the under side and all along the young branches. There are several trees at Leonardslee that have huge heads about twenty feet high, and each season at pruning-time all the vertical growths are taken off so that the flowers are in character with the drooping foliage. It is a native of the river banks of North Carolina. Any soil seems suitable for its cultivation.

Coroeka Cotoneaster.—This is a very curious New Zealand plant, sometimes called a dwarf, but plants 6 feet to 8 feet in height and still growing are not uncommon. The branches zigzag and

entangle in a very attractive manner. The leaves are small and white on the under side. The flowers are yellow and like little stars, and are produced very freely; in fact, it proves one of the most striking plants in the garden just now. It is quite hardy, though it is often supposed to be a tender subject. *Coroeka buddleoides* is quite a tender plant and must not be confused with the above; it is not half so attractive either, though it is often sent out as *Cotoneaster*, but the plants are widely distinct.

The Cricket-bat Willow.—Remarkably high prices are obtained for the special forms of *Salix* whose timbers are most prized by cricket-bat-makers. There is no doubt, says a writer in the current issue of the *Kew Bulletin*, that the timber of rapidly-grown trees is better for the bat-makers' purpose and of greater value per cubic foot than that of slowly-grown, comparatively stunted trees, which is contrary to what obtains with timbers in general. The best bat-makers' timber is that in which the annual rings are not less than half an inch wide. Trees on poor or comparatively dry ground will bring in neither so quick nor so large a return per cubic foot of timber as those grown on better, moister soils. This is a matter that should receive attention when a site is selected.

Hippeastrums at Glasgow.—There is a capital collection of *Hippeastrums* in the Botanic Gardens, Glasgow, where, from a good number of varieties of the best modern type, a great number of seedlings have been raised and the best carefully selected. They are well cultivated here, and are highly appreciated when in bloom by the many visitors to these Botanic Gardens, which, by the way, are maintained by the Corporation of Glasgow, and are well managed by Mr. James Whitton, the superintendent of parks, who is also curator of the Botanic Gardens. Mr. Rorke, an old Kewite, looks well after the plants in the houses, and he and his staff deserve much credit for the *Hippeastrums*. All the best colours are represented, and the groups are much admired.

Dendromecon rigidum.—For sheltered positions this somewhat rare shrubby plant is strongly recommended. Its yellow Poppy-like flowers are freely produced when it becomes established, and after being once planted it should not be removed, for it resents any disturbance at the base. The soil should be of a loamy nature, rather light and rich, while during a dry summer the roots may be mulched with partly-rotten manure. Propagation is effected by means of cuttings from shoots that are not too sappy. Each cutting should be placed singly in a small pot and kept in a frame till rooted. It is a difficult subject to increase, which probably partly accounts for its being rarely seen.

CORRESPONDENCE.

(The Editor is not responsible for the opinions expressed by correspondents.)

Darwin Tulip Clara Butt.—I saw a nice lot of this fine Tulip in a large garden the other day. There it is still highly prized as perhaps the most beautiful of its colour—a soft delicate rose with a slight blush tint on the outer segments. It well deserved the honour of being figured in the coloured plate of THE GARDEN for April 15, 1905, and the first-class certificate of the Royal Horticultural Society a few weeks later. It is not only delightful in its colour, but is most shapely in form; and in beds or lines, as well as in groups, it is not easily surpassed by any of this most useful class of Tulips.—S. A.

A Pretty New Fuchsia.—The new Fuchsia Benita, which is referred to in a leading note on page 237 of THE GARDEN for May 18, is indeed a charming one, and I can fully bear out all that is advanced in its favour. I saw a number of plants of this staged at a show, and took notes of it at the time. I also feel sure that it will receive an award in due course, as it is of so much more worth than some varieties already honoured. Judging from the general appearance of the plants, they will prove useful in pots and baskets, as well as planted out. The gardening public should see more of this charming Fuchsia.—G. G.

A Champion Sweet Pea.—One commonly hears enquiries for the most vigorous-growing Sweet Peas. Last year in Messrs. Dobbie and Co.'s seed farms at Marks Tey, Mr. Andrew Ireland noted a plant of Mrs. Cuthbertson the flower-stems of which each carried five blooms. The seeds were specially saved and sown. Among the progeny there is, or was on May 11 of this year, one plant carrying stems bearing respectively four, five, six, seven, eight and nine blooms. Seeds saved from this champion should next year give plants bearing anything up to eighteen blooms on a stem. Will this be the case? Messrs. Dobbie and Co. will doubtless be able to supply the wherewithal—seeds—to make the test.—H. J. W.

Wistaria sinensis.—The beautiful and fragrant flowers of the Wistaria are this season exceptionally fine. Here we have a very old specimen that occupies a warm position sheltered from the north-east winds, and at the present time it is a very pleasing sight, the blooms all over the tree being fully expanded. Last year the bunches of flower-buds were greatly injured, and only at intervals where the trusses were snug to the wall did the flowers open at all satisfactorily. The propagation of this Wistaria is not at all difficult, and anyone wishing to raise a few plants from any particular specimen can quickly do so by layering the young growing shoots, as almost every bud will form a plant.—H. MARKHAM, *Wrotham Park Gardens, Barnet.*

Phlox amœna.—Having recently seen a good mass of this charming little flower, I was reminded that it is not always easy to grow with success. I am writing of what I find the best treatment. The position of this class of Phlox means a good deal, and the general advice given is that all the alpine species require a sunny position. This recommendation holds good for such as *P. divaricata*, *P. stellaria* and *P. subulata*, which seem to revel in the sunniest position in the rock garden. With

P. amœna I have found that the brightest sun is not so good, but a slope to the north or north-west is much more suitable. In this position the plants make strong growths, which do not get burnt up as they do on the southern slope, and the plant is apparently much more at home in the partial shade, provided it is also out of any dampness during the winter months.—A. T. C.

Shrubs Under Trees.—In front of our County Hall at Kingston is a group of tall old Elms that many years ago were beheaded, and now have heads of dense growth, so that all beneath is literally shrouded. But, worse still, the soil is a mass of Elm roots; hence it is a matter for wonder how any shrubs can possibly exist planted close to the trees. It is just now most interesting to note in such a hungry, shaded position a handsome specimen of *Cytisus scoparius andreanus* quite a mass of flower, also full of good foliage. Evidently this is a Broom which in such root-eaten soil may be largely planted. Close by Box does well, also *Berberis stenophylla* (quite a nice dense, robust plant) and *Berberis Aquifolium*. How these shrubs managed to exist as they did through the intense drought of last summer, and now are in really luxuriant growth, presents a problem. Evidently they like the root dryness of the position. The Elms are within 4 feet to 5 feet of the shrubs below; hence it is seen that the root area must be a mass of fibres.—A. D.

Exhibition versus Private Garden Flowers.—In reply to "B.'s" criticism of my note, I think he has not quite understood it. I did not intend to decry professional florists' exhibits, which are usually most interesting, but only the general tendency to show flowers which mislead and grievously disappoint the unwary amateur. The herbaceous flowers staged at exhibitions do "suggest cut-and-come-again," and all too frequently fail to carry out that promise or have some fault that unfits them for small gardens, and so they delude and disappoint the ignorant amateur. Take, for example, Sweet Peas; the shows do not tell us that several of the "show" flowers require to be shaded to preserve their colour, and who of us wants to make our little gardens look like a laundry drying-ground? The Rev. J. Jacob shows an uncanny gift of reading between the lines, and sees that the poor amateurs want "someone who knows the way" of the Daffodils and other flowers to tell us which are likely to thrive in our gardens. I wish he would help us to a good, late, deep yellow trumpet for the garden. We have plenty of pale Narcissi at a poor man's price, but I fail to find a flower of a deep yellow akin to *N. bicolor grandis*, which is a joy to me with its happy, healthy flowers and foliage.—AN AMATEUR.

Hyacinths and Abutilons.—On page 238 of THE GARDEN, issue May 18, "C. T." refers to my notes on Abutilons under the above heading, and asks whether I have tried any of these plants in the flower-beds. My reply is Yes; I have grown them as dot plants in many large beds, and associated with other kinds of plants in sub-tropical bedding schemes. My article in THE GARDEN of May 4 dealt with the usefulness of the plant under glass. In North Lancashire and in Hampshire I have grown the Abutilon in the flower-beds, with very satisfactory results. The chief point is the due hardening of the plants before they are put out, so as to avoid the loss of basal leaves. In

the London and other parks Abutilons are often very extensively employed in the bedding-out schemes. I have seen them so grown, with charming effect, in Hyde Park. The variegated forms are the most useful for such work.—AVON.

—As stated by your correspondent "C. T." page 238, the employment of Abutilons for decorative purposes need not be limited to the indoor garden, as in the open ground they may be advantageously treated in various ways. Now that heds of mixed subjects (some of them in the shape of good-sized plants) are so popular for summer bedding, the Abutilons are of great service, and in some gardens are freely used in this way. Of variegated kinds, Abutilon Thomsonii, of upright growth, the lobed leaves of which are freely mottled with yellow, is especially effective as a dot plant, while another frequently met with is the rambling-growing *A. vexillarium variegatum*, which has small deep green leaves freely marked with gold, and red and yellow blossoms. This is often grown as a standard, under which conditions the semi-pendulous shoots show themselves to advantage. Souvenir du Bonn has large lobed leaves margined with white, while Sawitzii is a good deal in the same way, but less vigorous in growth and with a much greater amount of white in the leaf. The flowering varieties mentioned by your correspondent "Avon" all do well out of doors during the summer. One purpose, however, not referred to by either of the previous writers, and for which I consider some of the Abutilons particularly adapted, is for clothing the roof or rafters of a greenhouse. In this way the blossoms, owing to their strictly pendulous nature, are seen to very great advantage, while, what is also of considerable importance, they are produced throughout the greater part of the year.—H. P.

The Streptocarpus in South America.—Having read the interesting article on the cultivation of Streptocarpus in THE GARDEN for February 24, I thought perhaps you might be interested in a photograph of a group of these plants, taken about the middle of February (Midsummer). They are undoubtedly among the finest greenhouse flowering plants one could wish to grow. Here we have a small house holding over a hundred plants of Streptocarpus, intermixed with the same number of Asparagus plumosus, the first-named in 4-inch to 8-inch pots, and the latter in 3-inch pots. The effect is charming. The colours range from white tinged with blue and purple, lavender, and blues down to deep purple, also a few plants of a distinct rose tint. At the present moment the strain known as Cirrus is in full bloom. More delicate-shaped flowers one could not wish to see. They resemble a Cattleya more than any other flower I have seen. The size of these flowers ranges from 2½ inches to 3½ inches across. The cultivation of these plants is carried out on the same lines as those of your correspondent, with one exception, and that is the damping overhead. During the hot summer months (when the glass is at 90° in the greenhouse and falls to 85° in the afternoon) we have always damped the foliage in the afternoon, and so far have had no bad results from such treatment. If plant-lovers in the Colonies or any foreign country could be induced to send you short articles on plant species and their cultivation, it would be a great help to the public at large.—A. O. LOREN, *Quinta de Browning, Roldán, F. C. A., Argentine Republic, South America.*

Coronilla glauca Flowering Outdoors.—I am interested in the notes about *Coronilla glauca* which have appeared in THE GARDEN within the last few weeks, and I enclose a photograph of a specimen of it growing in the garden here, and which, at the time it was photographed about three weeks ago, and for a considerable time previous to it, was a complete mass of flower. It is growing at the end of a plant-house, and, consequently, protected by it, and measures 9 feet across and about four feet in height. Of course, the winters here are not so severe as on the mainland, as large trees of *Magnolia grandiflora* grow well in the open, as may be seen in the photograph, and Myrtles, which usually need the shelter of a wall, grow here unprotected.—A. E. P., *Ryde, Isle of Wight*. [Unfortunately, the photograph was not suitable for reproduction.—Ed.]

Exhibiting Daffodils.—I am much interested in the discussion on the above subject, and particularly so in several points in Mr. W. A. Watts' letter, page 226, issue May 11. With regard to the artistic arrangement of the cut flowers in competitive classes, I affirm it is of very secondary importance. A judge wishes to be able to see the points of every bloom at a glance, and is annoyed with anything that obstructs that clear view. If neatly arranged, both flowers in pots and cut in vases are artistic enough, and their value for garden decoration and market purposes can easily be appraised by the public. I, too, dislike the paper collars and any faking of the blooms. I once saw an exhibitor, just before the judges came round, deliberately tear away the fringes (faded) of a number of trumpets, and the judges, one a noted enthusiast, awarded the first prize to the collection including the faked flowers over others fresher and more meritorious.—B.

The Snowball Tree in Ireland.—I send two of the largest blooms of Guelder Rose (*Viburnum Opulus*) I have ever seen. They were grown in the garden of one of my parishioners. I have taken very accurate measurements of both of these blooms. One measures in circumference $15\frac{1}{2}$ inches, the other 16 inches. They were grown on a tree about fifteen feet in height. These gigantic blooms were both at the extremities of high branches. A very large number of flowers were in bloom, but the two I send dwarfed all the rest. I was given a bloom of *V. macrocephalum* this year. I was anxious to see it, as my plant did not flower. This species is said to be the largest flowered of all the *Viburnums*, but the flower kindly sent me was a pigmy beside the two Goliaths I send. The Snowball Tree is one of our best and most beautiful shrubs, as hardy as an Oak and as free-flowering as Whitethorn. It ought to have a place in a collection of flowering shrubs, no matter how small the collection may be. It is a thing of beauty and a joy for ever.—(Rev.) WILLIAM W. FLEMING, *Coolfin, Portlaw, County Waterford*.

FORTHCOMING EVENTS.

June 4.—Royal Horticultural Society's Meeting and Exhibition of Rock Plants. Masters' Memorial Lecture at 3 p.m. by Professor Bayley Balfour, F.R.S., V.M.H., on "Problems of Propagation." Scottish Horticultural Association's Meeting.

June 6.—Linnean Society's Meeting. Burnley Horticultural Society's Meeting.

June 8.—Stirling Horticultural Association's Meeting.

THE ROSE GARDEN.

DECORATIVE ROSES FOR THE HEARTH.

AN arrangement of Roses in the fireplace during the summer months is greatly appreciated, and much improves the general appearance of a room. The decoration rests on the style of fireplace; but whether an Adam, Georgian or old-fashioned ingle-nook, Roses can be arranged to suit all, and when the

CHERRY TREES IN POTS SHOWN AT THE INTERNATIONAL EXHIBITION BY LEOPOLD ROTHSCHILD, ESQ. (GARDENER, MR. J. HUDSON, V.M.H.)

grate is not attractive, a pretty fire-screen can be utilised. A screen, if used, should have a mirror; it will reflect a portion of the flowers and give an added coolness to the arrangement. Place the screen in the centre of the fireplace, and arrange vases of various height on each side and in front, filling them with water.

Next cut the blooms and foliage required, and set to work at once, taking care to nip a little off the stem of each before placing it in a vase; they last much longer when this is done, and one cannot expect the best results if the blooms are lying

about for an hour without water. If the fireplace is a large one, taller vases must be used and a big bowl placed in the grate. Where possible, the flowers can be arranged from the left side of the fender to the mantel-piece, finishing up the side of the mirror with a long flowering spray of one of the *wichuraiana* Roses, which will be prettily reflected again in the room.

The colour of the room must also be considered. Take care that the Roses used blend or contrast; a glare must be avoided. In rooms where blue, green or lighter colours predominate, Dorothy Perkins and Crimson Rambler are quite at home; but do not use them when the tone is red. Always bear in mind that the key to a successfully-arranged hearth is lightness.

One of the first Roses available after fires are dispensed with is *Una*. Cut long sprays with buds and open blooms, and arrange lightly with foliage of the *wichuraiana* Rose *Jersey Beauty*. *Juliet*, with foliage of *Alberic Barbier*, and *Beauté de Lyon*, with foliage of *Jersey Beauty*, are two of the early Roses especially noticeable because of their unique colour, and are really very elegant when nicely set up.

Electra, *Tea Rambler*, *Queen Alexandra*, *Blush Rambler* and *Alexandre Girault* come next, the latter being early and one of the finest of the *wichuraiana*s. When the foliage of the variety used is not decorative, add sprays of one of the *wichuraiana* Roses, *Irish Elegance* and *Lyon Rose*, with foliage of *Alberic Barbier* and long sprays of *rubrifolia*, once seen will never be forgotten. An arrangement of tawny yellow Roses of all shades was greatly admired; they were *Melanie Soupert*, *Marquise de Sinety*, *Lady Hillingdon*, *Mme. Ravary*, *Duchess of Wellington*, *Harry Kirk*, *Mrs. Aaron Ward*, *Arthur R. Goodwin* and *Miss Alice de Rothschild*, with long flowering sprays of *Shower of Gold*. This arrangement is greatly improved if a few blooms of the famous new *Rayon d'Or* can be found for the mantel-piece. Then we have *Dorothy Perkins*, *White Dorothy*, *Excelsa*, *Hiawatha* and several others of this tribe. All of them can be cut long, and last well in water.

When the ramblers are over, an arrangement of pink blooms is very attractive. *Lady Ashtown*, *Caroline Testout*, or any good pink, with a few blooms of the single *Rose Dawn* and sprays of *Alberic Barbier* and *rubrifolia*, *Mme. Abel Chatenay* buds and open blooms, with trailing *wichuraiana* foliage, are really charming. An arrangement of dark Roses, with *Hugh Dickson*, *Edward Mawley* or *W. E. Lippiatt* and the deep velvety crimson single *Rose Maharajah*, *wichuraiana* foliage and long sprays of *sericea Pteracantha*, is another success, the handsome red thorns of the latter showing up daintily among the shining leaves. E. E. F.

FEEDING POT ROSES.

THERE can be little doubt that Roses enjoy an extended rootrun, so they need considerable help when confined to the limits of a pot. In addition to a rich compost, they can be assisted by liquid manures. In fact, the judicious application of these is a great feature in their successful cultivation, and deserves a few words.

In the first place, I do not know of many subjects more easily suited as regards manure than Roses; but, like most others, they have some special favourites. Then we must perforce consider whether they are being grown for profit alone or for the adornment of the greenhouse and conservatory. It would be quite out of the question to use such manures and in the same way among

the latter as is often practised with market Roses, where we can mulch heavily among the pots and use more crude manures upon the surface of the pots than could possibly be the case in a private establishment. Personally, I have little doubt but that the Rose foliage feeds very considerably upon the ammonia arising from the manures. It gives more substance or texture to the leaves, and appears to keep the whole in better health and vigour, always provided it is not over-strong and the house is kept closed. I fancy, too, that insects have less effect; certainly we do not find red spider.

But my chief aim is to make a few comments upon the feeding of pot Roses as cultivated in private gardens, and, of course, we cannot employ

manures for pot Roses. The soot must be put into rather a fine bag, or there is apt to be a most objectionable scum on the top. A. P.

VEGETABLES AT THE INTERNATIONAL SHOW.

THE premier position for vegetables, in the opinion of those best qualified to judge, was easily secured by Mr. Edwin Beckett, gardener to the Hon. Vicary Gibbs, Aldenham House, Elstree, Herts, with a remarkable collection of subjects for so early in the season. Cultural skill of the highest degree of perfection was displayed in the

GROUP OF RHODODENDRONS SHOWN BY MESSRS. JOHN WATERER AND SONS AT THE INTERNATIONAL SHOW.

such methods there. A sprinkling of Clay's or Standen's manure upon the surface, having previously stirred over the latter slightly, does lasting good through washings by frequent water supplies. If a little light loam is placed over the manure, the whole has a fresher look and the presence of manure cannot be detected. It is seldom possible to remove surface soil from a well-grown pot Rose, because of the feeding roots so near to the top; but if the pots are not filled up quite so much at first, there will be useful room available for a fair mulching of some richly-prepared compost, and I have found the new roots simply revel in this, which must, perforce, be beneficial.

Liquid manures take a great place in the feeding of pot Roses. They are easily applied, and most establishments can get one of the most useful. Drainings from the cow-stall or those from the stock-yard are very satisfying. But one need be careful as to the strength when using, never losing sight of the fact that it is not only safer, but decidedly more beneficial when applied more freely, but in a weaker solution.

Guano may be used at the rate of 1½ oz. to the gallon three or four times a week. Of course, it is understood one will make some allowance for the comparative size of pot and plant.

A bag of horse and sheep manure, with a little soot, may be placed to soak in a tank or tub, and will result in a liquid manure free from any scum or sediment. This is more pleasant to use than that from farmyard drainage. As a matter of fact, I have found soot-water one of the best of all liquid

many vegetables staged by this well-known grower on a space 100 feet square. Varieties and kinds were very numerous, and they were set up in the inimitable way that this leading exhibitor has shown is possible for those who care to take the necessary trouble entailed. Everything was in the pink of condition, and among the many indispensable subjects worthy of special notice were Seakale, Asparagus, purple and white Aubergines, Peas and Beans in variety, Celery, Beet, Cauliflowers, Carrots, Tomatoes, Turnips, Cucumbers and a lot of other useful and popular vegetables. Dainty indeed was the setting up of this wonderful collection, and there is little doubt this exhibit afforded much interest for visitors, and also for those who devote themselves especially to vegetable culture.

The lady gardeners from the Thatcham School of Gardening, Berks, were evidently trying to emulate the exhibits from Aldenham House Gardens. On the present occasion their exhibit covered 50 square feet, and the produce staged by these ladies did them very considerable credit. Some thirty to forty different subjects and varieties were set up, embracing such vegetables as Cauliflowers, Cucumbers, Carrots, Onions, Potatoes, Turnips, Cabbages and other subjects, such as Lettuces, Radishes, Tomatoes, &c., all looking extremely well and evincing good culture. The grouping of the different vegetables and the comprehensive character of the display were highly praiseworthy.

Class 399, for twelve distinct kinds of vegetables, brought out three competitors, the produce in each

exhibit being exceptionally good for so early in the season. Asparagus, Peas, such as Duke of Albany and Centenary, Potatoes Ideal and May Queen, Tomatoes Winter Beauty and Perfection, Globe Beet, Flower of Spring and April Cabbages, Late Queen Broccoli and Magnum Bonum Cauliflowers, Improved Telegraph Cucumbers, Princess of Wales French Beans and Early Red Milan Turnips were all noteworthy.

There were only two entries in the class for nine vegetables distinct, and both were highly creditable. Giant French and Perfection Asparagus, Winter Beauty and Satisfaction Tomatoes, First Crop and Magnum Bonum Cauliflowers, Matchless and Pride of the Market Cucumbers, Exhibition Peas, Moore's Cream and Sutton's Cream Marrows, and Early Gem and Champion Scarlet Horn Carrots were splendidly staged.

Only one entry was forthcoming in Class 401 for six vegetables distinct, May Queen Potatoes, Sutton's Favourite Carrot and Magnum Bonum Cauliflower being the more meritorious.

Three exhibits of four varieties of Cucumbers, three fruits of each, made a good show. Matchless, Pride of the Market, Unrivalled, Mascot and Cynosure were the most attractive of the series.

In Class 407, for six varieties of Potatoes, nine tubers of each variety, there were several exhibitors. Balmoral Castle, New Colonist, Crimson Kidney, New Guardian, Empress, The Factor, King of Russets, Snowball, Royalty, Long Keeper and Purple Eyes were worthy of notice.

In another class for three varieties, Gladiator and Harbinger were noteworthy.

In Class 409, for a collection of salads set up in a space not exceeding 9 feet square, the only exhibitor showed a capital lot. Chervil, Ideal Cabbage Lettuce, Peerless Cos Lettuce, Solid White and Superb Pink Celery, Perfection Tomato, Globe Beet, King George Cucumber, Green Curled Endive, Crimson French Breakfast Radish, Nasturtiums, Watercress, Chicory, Onions and Mustard and Cress in variety contributed to make a really good display.

In a smaller class for a collection of salads there were two exhibits, both showing excellent collections of well-matured produce.

In Class 410, for six varieties of Tomatoes, six fruits of each variety, there were three capital collections staged. Eclipse, Winter Beauty, Satisfaction, Perfection, Princess of Wales, Best of All, Invicta, Peach Blossom and Money-maker were all very good.

In a small class for three dishes, distinct varieties, there were five exhibitors. Satisfaction, Sutton's Ar, Princess of Wales, Tuckwood Improved and Winter Beauty were each represented in a well-coloured, highly-finished condition.

In Class 413, for 100 heads of Asparagus, a mammoth bunch of Superb Giant easily out-distanced all the other competitors. Each of the four exhibits, however, was of a high order of merit.

Four lots of French Beans were shown in Class 415. Tender and True, Sutton's Forcing, Fulmer's Forcing and Masterpiece were represented.

In a class for a dish of Broad Beans, the four exhibitors set up Mammoth Longpod, Green Longpod and Giant Seville Longpod in capital form and condition.

Three exhibits of twelve Beets were praiseworthy, Sutton's Globe being chiefly in evidence.

For two varieties of Cauliflowers, six heads of each variety, the three exhibitors staged well. White Queen, Magnum Bonum and Clark's Challenge called for special mention.

There were four exhibits of three varieties of Carrots shown, and these were quite meritorious. Early Gem, Favourite and New Red Intermediate were represented in these exhibits.

Two magnificent exhibits were in Class 398, for twenty-five dishes of vegetables in the open division, not less than twelve kinds or more than two varieties of a kind. His Grace the Duke of Portland showed extremely handsome produce, representing among other subjects Flower of Spring Cabbage, Perfection and Eclipse Tomatoes, King George and Delicacy Cucumbers, Duke of Albany and Early Giant Peas, Giant French Asparagus, White Queen and Magnum Bonum Cauliflowers, Moore's Cream Marrow, Mammoth Longpod Broad Beans, White Leviathan Onion, Globe Beet, Supreme and Ideal Potatoes, Favourite and Champion Scarlet Horn Carrots, Perfection Green Marrow, White Gem and Early Red Milan Turnips, and Golden Ball and Ideal Cabbage Lettuce. This was a superb exhibit, and represented vegetables at their best.

In the other exhibit in the same class, Satisfaction and Eclipse Tomatoes, Sutton's Earliest and Flower of Spring Cabbages, Mushrooms, and Superlative Peas were well done.

For a collection of vegetables set up in a space 50 feet square there were two competitors. Cauliflowers, Tomatoes, Cucumbers, Carrots, Potatoes, Peas, Celery, Lettuces, Marrows, French Beans, Turnips, Asparagus, Seakale, Beet and many other subjects were set up in a dainty and attractive way.

There were six exhibits of a dish of Mushrooms in Class 420, one or two of the exhibits being beautifully even and of good quality.

In Class 421, for a dish of Peas, of the five exhibits Alderman, Hundredfold and Duke of Albany were to be seen in good form and condition.

Eight exhibits in the class for one dish of Potatoes found Ringleader, Balmoral Castle, Gladiator and King Edward VII. the most conspicuous varieties set up.

For nine tubers of a Potato not in commerce there were six excellent lots in competition. Sutton's New White, James Gibson, and The Rival (a seedling from Satisfaction) were the more noteworthy.

Generally speaking, Turnips were very poor.

In Class 426, for three dishes of three varieties of Turnips, there were three competitors. Early Snowball, White Gem, and White and Red Milan were all good.

MESSRS SUTTON AND SONS' EXHIBIT OF "FLOWERS FROM SEEDS" THAT WAS ARRANGED AROUND THE OBELISK AT THE INTERNATIONAL SHOW.

Radishes, three dishes of distinct varieties, were represented by six lots. Long Frame, Crimson Globe, Forcing White Turnip, Round White Tipped Scarlet Turnip, Forcing Olive and French Breakfast called for notice.

In Class 425, for three varieties of Rhubarb, nine sticks of each, there were two exhibits. Champagne (Hawkes), The Sutton and Hobday's Giant were the varieties staged.

There was only one lot of three varieties of Marrows in pairs, and these were quite good. Moore's Cream, Perfection and another white form were in evidence.

A grand collection of vegetables, open to growers for market, arranged effectively on a space not exceeding 100 square feet, brought out market produce to perfection—boxes of Tomatoes and Cucumbers, baskets of Peas, French Beans, Peas, Potatoes, Lettuces, Carrots, Mushrooms and Marrows in wonderful variety, all set up in a most attractive way. High quality characterised this really fine display, and there is little doubt it will be an object-lesson to many.

Messrs. J. Veitch and Sons, Limited, Chelsea, S.W., staged a grand non-competitive collection of vegetables set up in a most attractive manner. Veitch's Victor Peas growing in pots formed the centre of the group, and, in addition, there were, among other good things, All the Year Round Cauliflowers, Chilian Beet, Improved Nonpareil

Cabbage, Market Garden Cabbage, Ideal, Perfection, Improved Telegraph, Challenger and Sensation Cucumbers, Thomas Laxton Pea, Marvel, Invicta, Trophy, Victoria and Ham Green Favourite Tomatoes, Aubergines, Lettuces, Turnips, Mushrooms in variety and a host of other good things.

In the non-competitive section Messrs. J. Carter and Co., High Holborn, W.C., staged a large and comprehensive collection of vegetables, representing Cucumbers, Tomatoes, Cauliflowers, Carrots, Marrows, Potatoes, Beet, Cabbages, Lettuces and Turnips in considerable variety, and made an attractive display.

Class 394, for an effectively-arranged group of vegetables, for growers for market, brought forth a wonderful group of subjects of a most diverse character. The group was arranged in the form of a square, raised in the centre and gradually sloping to the edges. Most artistically were the different subjects grouped, and in many instances they served to represent vegetables in a high state of culture. This group was set up by Messrs. Vilmorin-Andrieux et Cie, Paris, a firm which have done much for vegetable culture in France.

From the growers of the Districts of the Paris-Lyons Mediterranean System splendid forced Asparagus and grand Globe Artichokes were displayed, as well as a large assortment of French Beans, Potatoes, Onions and other subjects.

A collection of Asparagus set up by M. G. Compoint, St. Ouen (Seine), was much admired.

Another large and comprehensive group of vegetables was staged by the Syndicate des Maraichers de la Region Parisienne, France, in which Cauliflowers, Carrots, Onions, Leeks, Cabbages, Lettuces, Turnips and other subjects were attractively displayed.

In the Belgian Section a fine array of good-quality vegetables were staged on long benches. Here were to be seen grand Cauliflowers, Cucumbers, forced Asparagus, Turnips, Celery, Rhubarb, Radishes, Lettuces and Mushrooms in large quantities.

Especially attractive was the large group of vegetables set up in the Dutch Section. The immense group was arranged in a most artistic way at one end of the tent devoted to the Dutch exhibits, and was certainly a most remarkable production. There were pyramids of Cauliflowers many feet in height, Cucumbers treated in a like manner, masses of Carrots, Lettuces, Asparagus, and beautiful salads, all grouped in a manner that exhibitors on the Continent are alone able to do, and all showing the work accomplished by growers there.

ROCK AND WATER GARDEN DESIGNED AND CONSTRUCTED BY MESSRS. PULHAM AND SONS AT THE CHELSEA SHOW

VIOLAS.

Mr. Charles Turner, Slough, set up baskets of lifted plants, in which many of the popular varieties were represented. Blue Duchess, J. B. Riding, Maggie Mott, White Swan, Mrs. Chichester, Bridal Morn, Admiral of the Blues, Jessie Baker and J. Pilling were the better plants.

In the display covering 100 square feet, Messrs. Gunn and Son, Olton, Warwickshire, set up an attractive group, which lost effect to some extent, however, owing to the somewhat crowded character of the display and the large number of plants of Moseley Perfection set up in the group.

Messrs. Seagrave and Co., Sheffield, made a capital display in the class for twenty Violas distinct. The plants were staged in an admirable way, and represented, among other good things, Countess of Eglinton, Mrs. Henry Wood, Mrs.

ODONTOGLOSSUM HER MAJESTY, A BEAUTIFUL NEW VARIETY SHOWN BY MESSRS. CHARLESWORTH AND CO. AT THE INTERNATIONAL EXHIBITION.

G. Charles, Gladys Finley, Agnes Kay, Mrs. Morrison, Dunbryan, Moseley Perfection and Mary Wynn. The group was beautifully set off with Selaginella and other plants.

In the non-competitive section Violas and Pansies were shown as growing plants. The collection looked very free and nice, and served to illustrate the beauty of these flowers. Virgin White, Duchess of York and Snowflake were good whites; Royal Sovereign and Klondyke, yellows. Edged sorts were represented by Waverley Blue Cloud, White Duchess and Mrs. Chichester; blue varieties by Maggie Mott and Archie Grant; and a fine lot of fancy Pansies helped to make a really charming exhibit.

Viola Moseley Perfection and a carpeting of Viola cornuta purpurea made a beautiful show in the big tent. The former is one of the largest yellow Violas, and the latter a wonderfully profuse bedding sort.

NEW AND RARE PLANTS.

NEW ORCHIDS.

FIRST-CLASS CERTIFICATES.

Odontoglossum amabile Duke of Portland.—A startling variety of an indescribable blending of red and purple, with bars of white on each segment.

Odontoglossum eximium King George.—One of the most outstanding varieties among this prominent genus, the brilliant scarlet maroon of the flowers being conspicuous from a long distance. These two novelties were shown by Messrs. Sander and Sons.

Odontioda Queen Mary.—This is a secondary hybrid between *Odontioda Vuylstekeæ* and *Odontoglossum eximium*. The flowers are light crimson, and the edges are shaded violet with a well-defined and thin white band within the

Odontioda Vuylstekeæ. Shown by F. Menteith Ogilvie, Esq.

Miltonia hyeana Vogelzang.—A handsome variety with exceptionally large ivory white flowers. The lip is of remarkable breadth, and the centre or "eye" of each flower is chrome yellow. Shown by Firmin Lambeau, Bruxelles.

Cattleya Mendelii Queen Mary.—A very taking variety of delicate hues. The lip is of a beautiful soft yellow.

Brasso-Cattleya The King.—The boldest and most noble flower of this section we have ever seen. The diameter across the sepals is about ten inches, and the flowers are most striking and of a glorious colour.

Dendrobium dalhousianum luteum.—Two admirable plants of this novelty were shown, each bearing a profusion of large flowers, pale yellow in colour, with dark chocolate maroon centres.

Cattleya Dirce magnifica.—A first-rate variety and a real improvement on the old form.

Lælio-Cattleya Lustre von Lavingo.—Yet a further improvement upon this beautiful and much-esteemed variety. For brilliance of colour it is hard to excel.

The foregoing were shown by Sir George Holford, and represent the most valuable set of novelties ever shown by one exhibitor at the same time.

Lælia purpurata schroderiana.—A magnificent variety of *L. purpurata* from Baron Schröder's collection.

Miltonia Jules Hye de Crom.—A capital variety, and one much coveted by connoisseurs. The pure white flowers, although undersized, have a broad lip and a very dark and almost black blotch in the centre. Shown by M. Jules Hye de Crom, Belgium.

Awards of Merit were granted to the following: *Odontoglossum ardentissimum* von Carmen (*O. Pescatorei Charlesworthii* × *O. crispum graireianum*), from F. Menteith Ogilvie, Esq.; *Cattleya Mossiæ* Mme. Jules Hye, from M. Lambeau; *Odontioda Bradshawia* var. *Vogelzang*, from M. Lambeau; *Lælio-Cattleya Lustre* var. *Buddha* and *Lælio-Cattleya Gladiator*, from Sir George Holford; *Odontoglossum amabile Princess Mary* (*O. hamyeus* × *O. crispum*), *Odontoglossum crispum* James McNabb and *Odontoglossum majesticum* James W. Whitton (*O. eximium* × *O. percultum*), from Messrs. Sander and Sons; *Lælio-Cattleya Ulysses* (*Lælio-Cattleya Fascinator* × *Cattleya Mossiæ ricickiana*) and *Lælio-Cattleya Ulysses alba*, from Messrs. Charlesworth and Co.; and *Zygopetalum Armstrongæ*, from Messrs. Armstrong and Brown.

NEW PLANTS.

FIRST-CLASS CERTIFICATE.

Leptospermum scoparium Nichollii.—A delightful evergreen shrub from New Zealand, every twig and branch being embowered with rosy red flowers. The plant is obviously of free growth.

AWARDS OF MERIT.

Leptospermum scoparium Boscawenii.—This is a much larger-flowered variety than the above,

margin. The markings are clearly shown in the illustration in last week's issue, page 263. The flowers are fine and large, and the lip is tipped with a band of white.

Odontoglossum Her Majesty.—A large flower of good form, and so heavily blotched with maroon that very little of the light groundwork is to be seen. These two gems were shown by Messrs. Charlesworth and Co.

Odontoglossum eximium Excelsior (ardentissimum crispum).—An exquisite variety, chocolate red in colour and fringed with white. Shown by M. Charles Vuylsteke, the celebrated Orchid hybridist of Loochristi, Belgium.

Odontioda Mrs. F. M. Ogilvie.—A charming variety, chestnut red in colour, surrounded by a darker zone and edged white with a suffusion of pink. The lip is white, with golden markings. Parentage: *Odontoglossum amabile* Royal George ×

and is of hybrid origin. The exhibited examples were about five feet high, the pink blush flowers rendered conspicuous by a great red eye or centre. The above two fine New Zealand subjects were exhibited by the Rev. A. T. Boscawen, Long Rock, Cornwall.

Hydrangea Sargentiana.—One of the most distinct species we have seen. The bracts are white, and emerge and extend on rather long drooping petioles. The leaves are large, obovate acuminate, the stems densely pilose. The plant appears to be of vigorous growth. Shown by the Hon. Vicary Gibbs, Elstree, and Messrs. James Veitch and Sons, Limited, Chelsea.

Papaver orientale Edna Perry.—This is a salmon-coloured variety with deeply-lacerated petals. Very showy.

Papaver orientale Perry's White.—This has handsome, large, finely-cupped flowers, whose rounded petals each have a huge black spot at their base.

Lilium davuricum luteum.—In all probability this is the true *L. davuricum* from Siberia, characterised by its densely woolly stems. The erect flowers are pale orange yellow, heavily spotted with crimson. These three plants were exhibited by Mr. Amos Perry, Enfield.

Polypodium Vidgenii.—A distinct novelty among Ferns, handsome and pleasing withal.

Lastrea patens Mayii.—This is said to be of hybrid origin, and is certainly a good addition to greenhouse Ferns. These were exhibited by Messrs. H. B. May and Sons, Limited, Edmonton.

Deutzia Veitchii.—A most delightful plant, with large flowers of rosy pink colouring appearing freely from Viburnum-like leafage. A delightful acquisition that must take first rank among hardy flowering shrubs. Shown by Messrs. James Veitch and Sons, Limited, Chelsea.

Pyrethrum Queen Mary.—This plant has been before the floral committee on more than one occasion, but never before has it been displayed in such profusion or richness of colouring. It is a double pink-flowered variety. Exhibited by Mr. G. W. Miller, Wisbech.

Lilium myriophyllum.—This handsome trumpet Lily has probably been known to botanists and specialists in this country for half-a-dozen or so years. It is virtually a *Brownii* form in point of flower, whiter generally, and with the narrow leafage almost of *tenuifolium*; hence it is a distinct plant, and withal a good doer. It is a native of China, and promises, by reason of its easy culture and free-flowering, to become popular in gardens. A first-class plant in every way. From Messrs. R. W. Wallace and Co., Colchester.

Oxalis enneaphylla rosea.—This is just a rose-coloured form of a beautiful species from the Falkland Islands that puzzles not a few cultivators in this country at the present time. We should

like to have seen the plant in a more promising or congenial mood. From Mr. Clarence Elliott, Stevenage.

Eremurus Tubergenii.—A yellow-flowered sort, presumably *E. Bungei* and *E. robustus* crossed, though we have no information to this end. The great spires of primrose yellow flowers are very beautiful. Exhibited by Messrs. R. W. Wallace and Co., Colchester.

Begonia Princess Louise.—This is a double-flowered variety, and in all probability one of the most gloriously beautiful of the salmon-coloured shades yet raised. The handsome flowers are

woolly stems and leaves. From Bees, Limited, Liverpool.

Iris squalens Nibelungen.—The standards are clouded, the falls crimson-red.

Iris variegata Ossian.—Standards yellow, falls reddish. These were from Messrs. Barr and Sons, Covent Garden, W.C.

Sweet Pea Mrs. Cuthbertson.—A bicolor with pink standards and white wings.

Sweet Pea Brunette.—This is a self maroon coloured variety.

Sweet Pea Melba.—The colour is salmon, and of a tone valuable and pleasing in decorative work. These were exhibited by Messrs. Dobbie and Co., Edinburgh.

A THREE YEARS' OLD PLANT OF SAXIFRAGA CÆSPITOSA.
(See page 284.)

6 inches across, and are as remarkable for great depth as for size. Exhibited by Messrs. Blackmore and Langdon, Bath.

Calecolaria Veitchii.—A most charming and graceful plant, the result of crossing *C. alba* with an albino form of *C. Golden Glory*. The exhibited examples were 5 feet high, and characterised by narrow, acutely-pointed serrated leaves. The flowers are of ivory or creamy white, and produced in wonderful profusion. A great acquisition. Exhibited by Messrs. R. Veitch and Co., Exeter. Illustrated in our issue for May 25.

Celmisia spectabilis argentea.—A New Zealand species with white flower-heads and rather white

NEW ROSES.

THERE were some really good novelties on view at this wonderful exhibition, although perhaps nothing of a startling character.

Rosarians are always on the alert for something great to be produced, and all who engage in the work of hybridising are fully aware of the great possibilities to be achieved sooner or later.

Although not exhibited in any force, owing to the trying weather recently experienced, Messrs. Alex. Dickson and Sons had sufficient of their grand novelty.

George Dickson, to show visitors what a superb advance it is. When such successful raisers as Messrs. Dickson tell us it is the best thing they have yet produced, no further commendation is required. I have seen the Rose before, and shall never forget the wonderful boxful put up at Ulverston, which secured the unanimous vote of the judges for the gold medal. Perhaps the most beautiful novelty was one from M. Pernet-Ducher.

Mme. Edouard Herriot. This is a real gem in colour, and one that it is difficult to describe. It is a sort of crimson terracotta, with all the fiery colour of Mrs. A. R. Waddell, and also some of *Beauté de Lyon*, combined. Although belonging to the Pernetiana race, it is as free as a Hybrid Tea. This Rose was awarded the special cup as the best novelty.

Freda I believe to be the next best novelty. It is one of which Messrs. Paul and Son of Cheshunt may be justly proud. The depth of bloom and fulness are truly superb, and the colouring is a lovely tint of rose pink. Exhibitors have not had a more useful Rose than this for a long time, and, judging from its strong growth, it should be equally grand as a garden variety.

Mrs. E. Alford may be best described as a fuller and more superb *Mme. Abel Chatenay* with the grand contour of a very superior *La France*. The long, stiff stems proclaim it a splendid forcer.

Mrs. George Beckwith is a wondrous colour, resembling *Rayon d'Or*, but with a superior form

and apparently strong, erect growth. This and one named Constance came from M. Pernet-Ducher, and both favour Rayon d'Or in the glorious deep yellow colouring. The notorious

Sunburst was not shown in quite its true character. Some flowers were of the deep golden colour of Lady Hillingdon, but others of the first growth were quite pale. It is, nevertheless, a superb bloom, the petals of great texture and the form grand. It is a sort of glorified Mrs. Aaron Ward, still one of the loveliest of Roses for the greenhouse as well as for the garden, but the growth of Sunburst is longer, more of the Antoine Rivoire type, carrying the blooms quite erect. It may not supplant Lady Hillingdon in midwinter, but will be a far better Rose from the second growth.

Alexander Hill Gray was in exquisite form from Newtownards, and I predict for it a great future. The clearness of colouring and the large petals are truly beautiful. Probably the yellow colouring will be even deeper outdoors.

Melody is another good thing from Ireland. I am not surprised this Rose is going strong in America, for there is a superb finish and fulness about it that must commend it to all.

Sallie secured for Messrs. B. R. Cant and Sons a first prize. It is a fine Rose of the Joseph Hill type, but richer in colour. It will be a grand variety for the exhibitor, also for the garden.

Mme. Charles Lutand is of splendid growth, also form, and I believe from the second growth will be a formidable rival to Marquise de Sinety. As seen here the blooms were paler.

Ophelia is a pretty Hybrid Tea of tints and growth, reminding one of Clara Watson, only not so full. P.

FLOWER GARDEN.

WORK AMONG THE AURICULAS.

Potting.—It has already been pointed out in this column that the month of May is usually the best for potting plants which demand such attention; but if it could not possibly be accomplished by the end of last month, let it be finished with the utmost despatch now that June is in. Bear in mind that any material delay now will force the postponement of the operation until the late summer, and this cannot be regarded as satisfactory. Use a plain compost in which sound, fibrous loam plays by far the most important part, and see that the tap and any other roots which are not in perfect health are cut away before the plant goes into the fresh soil. With the object of reducing the necessity for too frequent watering afterwards, keep the frame a little closer to reduce the evaporation. Any plant, no matter what its size or age may be, or whether it demands repotting or not, which shows the

slightest indication of being in ill-health must have instant attention, as it is commonly found that an American blight-like animal is attacking the roots, and unless it is promptly destroyed the plant will soon be ruined.

Watering.—It has been suggested in the preceding paragraph that plants which have just been potted must have no more water than is absolutely imperative; but established specimens require regular supplies if they are to continue in satisfactory condition. It must not be inferred from this that it is suggested to give water every day, because nothing of the kind is meant. The thing is to study the plants so closely and intelligently that the necessity for water is

unfavourable to the enemy, as prevention is always preferable to cure. The frame should be given a northern aspect, not only because this is exceedingly beneficial to the plants in the summer months, but also because the thrips do not like the cool atmosphere which is favoured by this simple expedient. Red spider, too, will make its presence felt in arid frames, so that much good follows the cool aspect and the correct watering. If it should become necessary to use an exterminator against enemies of this nature, I know of nothing superior to XL All for the purpose.

An Insidious Enemy.—Among young plants, or even among the young leaves of old plants, there is no enemy that causes so much trouble and worry as a small, dark-coloured maggot, which bores into the heart of the plant and will cause its death in a very short time. The keenest watch alone will suffice to detect its presence, and the outward and visible sign takes the form of a drawing together of the small leaves with an extremely fine web. Immediately this is seen, examine the plant minutely, because it will almost always be found that between the folds of the leaf so cleverly drawn together a dark maggot will be seen. Growers will not demand a suggestion from me or any other writer as to the readiest means of meting out instant death to the intruder.

Plants in Seed.—The amateur who indulges in cross-fertilisation in the hope of producing varieties superior in merit to any now in cultivation has a difficult task in front of him; but if he proceeds on intelligent lines he is sure to produce something that will bring him infinite pleasure. At the present time, in normal conditions, the seeds will be developing steadily, and in the ordinary course of events they will ripen between the beginning and the end of July. It is not desirable that these plants should be disturbed for potting, and, as a rule, the seeds will be the better if rather less water is given than to the bulk of the collection. F. R.

ROSE MME. EDOUARD HERRIOT, THE BEST SEEDLING ROSE SHOWN AT THE INTERNATIONAL EXHIBITION. RAISED AND EXHIBITED BY M. PERNET-DUCHER.

anticipated by a few hours, as this will mean that the soil in the pots can never become dry on the one hand or sodden on the other. An equable condition of soil moisture is peculiarly conducive to success.

Thrips.—It is something to be regretted that yellow and black thrips show a marked partiality for Auriculas; but they only appear during hot, dry weather, so that it is not difficult for the cultivator to be prepared to give them a more cordial reception than they are able properly to appreciate. Immediately an attack is observed—and it must be seen early to prevent real injury—take reliable steps to suppress it. Better still, however, is it to endeavour to create conditions that are

alpine plants here at Woodford, and makes an excellent subject for carpeting a semi-moist bank halfway down some steeply-sloping part of the alpine garden, where it will not receive the fiercest of the sun's rays. The plant illustrated on page 283 consisted of a 2½-inch potful rather less than three years ago, and has now, without any further attention, made a patch 2 feet 6 inches in diameter. The flowers are very pale cream, and are produced in such quantities as to entirely hide the foliage. The soil I give it is just ordinary garden loam (by no means of the best) well mixed with grit and a little leaf-mould. The position halfway down the bank of rockwork and facing west ensures its roots being moist. R. A. MALBY.

SAXIFRAGA CÆSPITOSA.

THIS, one of the Mossy section of this beautiful and interesting family, is one of the freest of my

GARDENING FOR BEGINNERS.

TYING DOWN AND STOPPING VINES AND THINNING GRAPES.

ALTHOUGH Vine shoots are tough when matured and will withstand much bending and still not break, they are very brittle when in a young state, and, in fact, until the berries begin to swell freely. This being recognised, the cultivator must exercise considerable care when tying down the young shoots to the wires under the glass. The work must be done gradually; if they are in the first instance brought down level with the wires, they will snap off. First of all, the tips should be pinched off and the ends slightly pulled away from the glass and made secure to the wires with soft strands of matting. In a few days' time the shoots may be depressed 2 inches more, and so on until they are brought down to the wires as shown in the accompanying sketch.

Now, it is very important that the whole of the roof space be covered with foliage, but only with the main leaves and the first leaf (c) on each lateral shoot. From the main rod, A, the side shoots or branches will grow as shown, alternately, one on one side and another on the other side; then the branches of the Vines will dovetail, as it were, into each other, and so completely furnish the roof with healthy foliage without causing any overcrowding.

The Illustrations Explained.—Fig. 1: A, Vine rod; B, a side shoot or branch growing from a spur; C, a lateral growth, which must be stopped at the first leaf, the one leaf only being retained throughout the summer; the sublateral shoots which grow from its base must be regularly removed while they are quite small. Not more than one bunch of Grapes must be allowed to mature on a

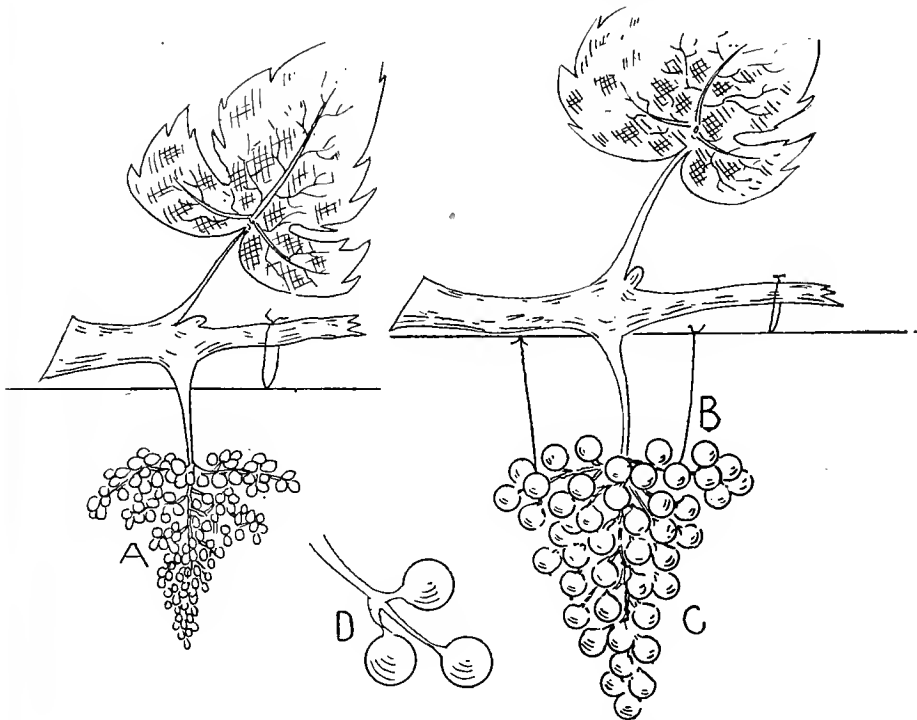

1.—VINE SHOOTS MUST BE TIED DOWN GRADUALLY, OTHERWISE THEY WILL SNAP OFF.

branch, and the latter should be stopped at two joints beyond the bunch, as shown at D. The individual Vine must only be allowed to mature 1lb. of Grapes per foot run of main rod. One large leaf, kept healthy and with ample room to grow in, will be of more value than three leaves occupying the same space.

Thinning-Out the Berries.—The amateur should never be in too much hurry to cut out the berries

from the bunches, as they should be left to grow large enough to show which are well "stoned" and which are not. On the other hand, undue delay in the matter of thinning would not prove very satisfactory, as the berries left in would get marked and not swell to as large a size as they should. Vines growing in cool structures and greenhouses start growth almost naturally, and are not ready for thinning as soon as those assisted by fire-heat, but the Grapes finish well in ordinary seasons. A bunch unthinned, as shown at A (Fig. 2), contains, if the "set" has been a good one, at least three times more berries than should be left to mature. In the first place, the cultivator must cut out the very small, stoneless berries, using a pair of bright, dry and clean Grape scissors. The berries left must not be touched with either hands or tools. A smooth, forked stick may be used to steady the bunch while the surplus berries are being cut out; B shows how the shoulders must be neatly tied up to the wires, and C depicts the bunch after being thinned, the berries swelling freely. The cultivator must commence at the bottom of the bunch and remove the surplus berries upwards, also from the extreme ends of the shoulders, and finish at the top of the bunch. More berries may be left, in proportion, at the top than at the bottom, because there is more room there for them to swell in. Usually there are three berries at the extreme ends of side shoulders, as shown at D; these must not be cut out. Short-stemmed berries require more severe thinning than long-stemmed ones.

G. G.

2.—BEFORE AND AFTER THINNING. IN THE UNTHINNED BUNCH THERE ARE AT LEAST THREE TIMES MORE BERRIES THAN SHOULD BE LEFT TO MATURE.

TOMATOES AND SIDE SHOOTS.

At this time of the year side shoots appear from the axils of the leaves and main stem with remarkable rapidity. All side growths should be pinched out in the early stages; this will give greater nourishment to the trusses of fruits forming on the main stem.

GARDENING OF THE WEEK.

FOR SOUTHERN GARDENS.

Plants Under Glass.

Primula malacoides.—This new Primula, of comparatively recent introduction, makes a charming plant for the cool greenhouse in the early spring months. To obtain nice plants, sow the seeds now.

Chrysanthemums.—The work of the final potting will soon be engaging attention. To ensure success it is desirable that a suitable compost be prepared for them, and if this is mixed and prepared a week or so beforehand, it is to be preferred. Avoid having this too fine; the staple part should consist of good, fibrous loam, to which add some leaf-mould and spent Mushroom-bed manure, according to the nature of the loam, together with a sprinkling of soot, wood-ashes, a little patent plant food, with a liberal addition of coarse road or river sand. Thoroughly harden the plants before potting, pot firmly, and if space is left for further top-dressings, this will be an advantage.

The Flower Garden.

Verbenas.—When well grown, few of the occupants of our borders during the summer months create a greater display. On well-prepared ground these grow freely, when attention is given them as to pegging down the growths. Allow the plants at least a foot apart, and sprinkle with a rosed can in the evening.

Sweet Peas.—The earliest flowers from the autumn-sown plants will soon be ready. With these, and those sown later, any little attention required, such as tying up the haulm, should be done. A little nitrate of soda sprinkled beside the rows in showery weather or well watered in may be given, but avoid an excess.

Pentstemons.—The seedlings raised this year will now be fit for planting out, and will give a grand display in the late summer months. Keep the Dutch hoe going between the plants. Seedlings raised from a good strain are preferable to cuttings, as when the latter method of raising is continued year after year the vigour of the plants deteriorates.

The Rose Garden.

Climbing Roses.—These are growing apace and will need tying in to the poles or pergolas. Let the work appear when finished as natural as possible, so that the flowers when they expand are seen to their best advantage. If the plants are attacked by aphid, syringe thoroughly in the evening.

Mildew.—This, if allowed to go on unchecked, will soon disfigure and exhaust the plants' energies. Syringe with a solution of sulphide of potassium, half an ounce to the gallon, or dust the foliage with black sulphur when the dew is on the plants, or the foliage may be damped with a syringe producing a fine spray.

Roses on Walls.—During hot weather especially the growth of these will be much accelerated and the quality of the flowers improved if the growths are syringed either in the early morning or evening. Apply a good mulch to the surface of the soil and water copiously, as Roses in such positions frequently derive but little benefit from occasional rains.

Hardy Fruit Garden.

Currants.—The bushes of Red and White Currants will benefit for more reasons than one if the shoots are tipped back within a week or so. In the first place, aphides are removed and more air and light can reach the fruits, while the appearance of the bushes is improved, and admits of a covering of nets being placed on with greater ease as soon as the berries commence to colour.

Gooseberries.—Where heavy crops of the best dessert varieties are hanging on the bushes and good fruits are wanted later on, the fruits can be thinned now for preserving and for use in the kitchen, which will allow the remaining berries to swell to a larger size.

Fruits Under Glass.

Late Houses of Peaches and Nectarines.—Make sure that the borders do not suffer for the want of water. With frequent syringings it often happens that the borders appear well supplied with moisture, as they are on the surface,

but the lower parts of the border are quite dry. Apply stimulants, except while the fruits are stoning, when the trees should not be excited in any way. Give plenty of air, syringe twice daily, and damp all surfaces of the house.

Fire-heat.—During the next month or two little assistance should be required by artificial heat, especially with Muscat and midseason Grapes. For Figs and Melons a slight circulation is wanted in the pipes at night, and the extra expense is well repaid. When the weather promises fine, the heat should be shut off or the fire allowed to go out quite early in the day.

The Kitchen Garden.

Celery.—Continue to plant out for late supplies. Choose showery weather for this, if possible, and as quickly as possible plant after lifting with a good ball of soil attached. Give a good watering in and keep the plants damped over. Once a week give the plants a dusting of soot, which will do much to ward off the fly.

Leeks.—For late kitchen use make a further planting. Select a shady part of the garden, bore holes with a dibber and drop the young plants to the bottom, and close in with some of the finest soil at the roots.

Potatoes.—Earth up the crops of these as becomes necessary, and where the growths are too numerous, thin out the weakest, or a heavy crop of haulm will be grown at the expense of the tubers.

Onions.—The transplanted ones that were raised in heat at the beginning of the year should have the soil between the rows constantly stirred with the Dutch hoe, and be damped over as often as possible in the absence of rain. Give a dusting of soot occasionally, and as soon as these are growing freely a little artificial manure may be given during showery weather. The main crop requires similar treatment. Carefully hand-weed when necessary in the rows, and pull evenly from the bed as required for salads, etc., but not too severely.

E. BECKETT, V.M.H.

Aldenham House Gardens, Elstree, Herts.

FOR NORTHERN GARDENS.

The Fruit-Houses.

Grape-Thinning.—The late Hamburgs and Alicantes are now at the thinning stage, the former needing a much less number of berries to be removed than the latter. Ugly shoulders should be cut off.

Feeding Vines.—Long-established Vines must be well fed to be satisfactory. At the above stage it is therefore important to apply to the borders a dressing of sifted pigeon-manure, being careful to keep the top ventilators slightly open at night to allow of the escape of noxious gases. Soot is also beneficial, and when applying water to the borders let it be strengthened with a soluble manure.

Peaches.—Before the fruits mature on early trees, soak the borders with water, and if there is the least fear of red spider attacking the foliage, syringe with a solution of Quassia Extract. This may be supplemented by fumigating the structure with Tobacco cloth, but always bear in mind that the Peach is easily damaged by insecticides, and Tobacco fumes especially. Pinch out all the lateral growths which push from the axils of shoots of the current year. The ventilators of Peach-houses need never be closed during the summer months unless for hastening the ripening of a particular crop.

The Flower Garden.

Plant-Supporting.—See that the slower-growing perennials are not left without supports. A piece of string lightly fixed round the stems is often sufficient.

Tuberous Begonias.—These may now be planted. Ours for planting out are forwarded in boxes thinly disposed, and transplanted with large balls of roots and soil. They should be rather deeply planted, so that the tubers are covered with at least 2 inches of soil and the roots well into the ground. Soak the soil of the beds as planting proceeds, and if a carpet of Lobelia or other low-growing plant is contemplated,

delay planting till the next day, when the ground will be in a fit condition to work.

Dahlias.—Plant these at once to ensure a not too late bloom. These are voracious feeders, and provision to meet their requirements should be made before planting. Some growers prepare the site of each plant by the addition of compost. If the soil is at all inclined to dryness, soak it with soft water on the conclusion of operations, which should include a light stick to which to tie the shoot, to be afterwards replaced by a stout stake. I am using for effect a few of the large-flowered kinds, of which Souvenir de l'Douzain is the chief; also Geisha, Liberty, Grand Duc Alexis, Beauty of Arundel and others.

Reserve Plants.—A small percentage of those plants which experience shows sometimes fail in part to grow should not be kept in the receptacles in which they were prepared for planting-out, but either in others where fresh soil and more space can be given them or in a reserve quarter of the kitchen garden. In addition there should be a quantity of late-flowering plants provided, such as African Marigolds, China Asters in variety and Chrysanthemums, of which I annually use a very large number for transplanting while in flower. Besides these it is essential to pot up Lobelias for stock, and Iresines and other tender things should also be preserved for the same purpose.

The Plant-Houses.

Hippeastrums.—As soon as seeds are matured sow at once, by which practice a year at least is gained in the flowering of the seedlings.

Tree Carnations.—Be careful after this in stopping. Cuttings of scarce varieties rooted last month need not be stopped at all, but left to grow with a central stem and the natural breaks, which are sure to become strong before autumn. Five-inch pots are the correct size for these.

Chrysanthemums.—The final potting of these should be accomplished forthwith. Souvenir de la Petite Amie, niveum and Miss A. Pockett are invaluable grown in 6-inch pots for Christmas, and many of the singles also do well in small pots; but for cut flowers they produce many more when larger pots are used. Miss Margaret and Annie Lowe are splendid for cutting, and of these several may be potted into one receptacle, as they do not break freely. It saves a large amount of labour in watering to plunge the pots, also after-annoyance if the plants are staked at once and made secure from winds by fixing them to wires or other supporting material.

Insects.—These multiply if left unmolested at an amazing rate during the summer months. The mite on Begonia Gloire de Lorraine can only be kept down by nicotine vapouring; thrips on Dracenas by the same means or dipping in water at 150°. Mealy bug on many kinds of plants is easily destroyed by dipping the plants in hot water, by spraying frequently with an approved insecticide, and by dusting with Tobacco powder. If it gains a footing on Grape Vines, repeated syringing with water that has been boiled and allowed to cool to 150° to 180° kills the insects and scarcely damages the clusters of Grapes, due care being observed. Quassia is excellent for aphid.

The Vegetable Garden.

Onions.—A dressing of soot and any other suitable manure should be applied now that the plants are growing vigorously, and the surface be thereafter stirred.

Parsley.—The main Parsley-bed should be planted from seedlings raised in the open. Set about twelve inches to fifteen inches apart in nice friable, but not too highly-enriched soil, which causes a coarse growth. Dress the ground with soot as a preventive of root maggot.

Seeds to Sow.—A little Endive may be sown for use in autumn, and the very dark-hued Beets, such as Cattell's, should not be sown earlier, else they will grow too coarse. Also sow a few seeds of London Colewort, waiting a fortnight to make the main sowing. This is a useful vegetable not much grown in the North. At the same time sow seeds of a good second-early Cauliflower. Spinach, Mustard and Cress, Radishes and Lettuces must be sown at short intervals not exceeding ten days, and Lettuces should be regularly transplanted, a few at a time, in order to secure a constant supply.

R. P. BROTHERSTON.

Tynningham, Prestonkirk, N.B.

HORTICULTURAL SUNDRIES AT THE INTERNATIONAL EXHIBITION.

The Leyton Timber Company, Leyton, Essex, were showing rustic summer-houses, garden seats, tables, garden furniture and fencing generally.

The Twelve Hours Stove Syndicate, Westminster, had a most useful exhibit of their well-known twelve-hour stoves, suitable for heating amateurs' greenhouses, ranging in various sizes, which could be adapted to meet all requirements.

Messrs. James Crispin and Sons, Bristol, showed greenhouses and conservatories suitable for either large or small gardens, which were well built and adapted for all classes of plants. In addition, the special boilers of the independent saddle type, namely, "Mona," "Robin Hood" and "Senior," were shown in various sizes.

Messrs. James Weeks and Co., Chelsea, were exhibiting greenhouses and heating apparatus generally. Among the latter was to be noticed one of the "Strebel" boilers, with an automatic draught attachment for regulating the fire.

Messrs. Skinner, Board and Co., horticultural builders, Bristol, showed a specimen greenhouse built on their well-known wire tension principle, having a curved iron framed roof. The greenhouses built on this system are easily portable and practically imperishable, as there is no putty to require constant attention and repair, and the maximum amount of light is thus obtained.

The Fernden Fencing Company, Tothill Street, Westminster, S.W., had a pretty and artistic arrangement of fencing and trellis-work in various forms.

"Dryad" furniture was shown from Mr. H. H. Peach, Thornton Lane, Leicester. His celebrated cane manufactures are most suitable for garden and summer-house work.

Messrs. George F. Braggins and Co., Banbury, Oxon, were showing gates suitable for garden and estate work of all descriptions, and a very useful form of hand-cart.

Mr. John Pinches of 3, Crown Buildings, Camberwell, showed the well-known "Acme" labels and wire goods, one of the specialities being a Rose box, the lid of which lifts off quite easily. Two wire supports may be placed through holes at the back of the box in order to raise it on the exhibition table sufficiently high to show off the blooms to the best advantage without the use of blocks, as used in the ordinary way. This is claimed to be the lightest box on the market, which is a consideration to exhibitors. Rose trainers of all descriptions were shown. A special machine for packing Roses and other tall-growing plants, which folds up quite close, and firmly holds a covering around the plants with a ratchet adjustment, to any size, until the packet is completely strung, was also shown. It is composed of a series of semi-circular rings, which either open wide or close up at will.

Messrs. Pulham and Sons, Newman Street, Oxford Street, London, had a large and varied selection of stone garden ornaments, including vases, fountains, sundials and other special forms.

The Thames Bank (Blackfriars) Iron Company, Limited, Upper Crown Street, E.C., were showing several of their special lines in heating apparatus, including upright and horizontal tubular boilers, and the "Crown" and "Economic" as special lines; also the "Heel" boiler for amateur work.

Mr. H. C. Slingsby, Old Street, E.C., was showing the Slingsby steel-backed ladder, a light form which is very strong and durable.

Messrs. Rowell and Co., Old Queen Street, Westminster, were showing iron fencing, tree guards and trainers of their well-known make.

Messrs. Höntsch and Co., Niedersiedlitz, Dresden, had a smart exhibit, including a section of greenhouse showing the ventilating gear and construction complete, together with several small models of the various types of greenhouses and conservatories which they are prepared to construct.

Messrs. Walters and Co., Amberley Grove, Croydon, who are famous for their artistic trellis-work, fencing and garden furniture, had an effective display in up-to-date designs.

Messrs. T. Crowther and Son, North End Road, Fulham, had a most interesting exhibit of unique garden ornaments, including old stone vases and wells, lead vases and pedestals, garden seats and temples.

Messrs. Lloyd Lawrence and Co., 29, Worship Street, E.C., had examples of their famous Pennsylvania lawn-mower in all sizes, also seed drills and the well-known "Planet Jr." hoes.

Messrs. S. and E. Collier, Limited, Reading, were showing pottery in many varied and artistic forms.

The German Potash Syndicate, 117, Victoria Street, S.W., had an interesting exhibit showing plants in various stages of growth which had been treated with additional potash.

Messrs. C. P. Kinnell and Co., 65A, Southwark Street, S.E., had a most representative selection of their well-known goods on view, including the "Rochford," "Bisson," "Covent Garden" and "Anglian" boilers. The last-named was represented by a monster capable of heating from 11,000 to 12,000 feet of 4-inch piping. In the 11,000 size of this boiler a great advance has recently been made. One of the sections had been arranged with the flow coming outwards on both sides, which may be had entirely in this form if required. This is a most important factor for those who depend on shallow stokeholds. This boiler, working up to 2,700 feet of 4-inch piping, can be set in a depth of 4 feet 9 inches, which is a saving of at least 9 inches over those having top flows.

The Hon. Mrs. R. C. Grosvenor, designer of gardens, Morrisburn House, Woking, had an interesting page with a thatched summer-house and a selection of garden ornaments, surrounded by an artistic fencing arrangement.

Messrs. Vipan and Headley, Limited, Leicester, were showing garden furniture of all descriptions, and also the "Wyvern" lawn-mower, which is entirely hand-made, and a solid oak Rose temple.

Messrs. William Duncan Tucker and Sons, Limited, 27, Cannon Street, E.C., the well-known horticultural builders, had some excellent specimen plant houses and conservatories on view, together with other specialities for which this firm is noted.

Messrs. William Poupart, Limited, Fernleigh Orchards, Twickenham, had a large and varied exhibit of bottled fruits, which were clearly and carefully preserved in the best possible manner.

Messrs. Macmillan and Co., horticultural publishers, London, were showing a choice selection of standard works in connection with gardening.

Messrs. G. Jackman and Sons, Woking, Surrey, had a nice selection of garden plans and designs. This firm also showed a model of their tree-planting machine, which enables large specimen trees to be removed and transplanted at any

distance. The exhibit was situated in the open near the south-east end of the large tent.

Miss Helen Colt of Hampstead had an exhibit of models showing the possibilities of what may be done in town and suburban gardens.

Miss Wheeler, Hampshire, also showed photographs and views of students' work in school gardens.

Messrs. Charles Letts, diarists, London, had specimens of their well-known diaries in all sizes on view.

Messrs. J. Pither, Limited, Uxbridge, Middlesex, were showing examples of Mushroom spawn.

The Selborne nesting-boxes were shown by Mr. Wilfred Mark Webb of Odstock, Hanwell.

The Pwllbach Colliery Company, Limited, Swansea, were showing specimens of their well-known horticultural coal in various grades.

Dansyz Virus, 52, Leadenhall Street, E.C., were showing their well-known rat poison, which, although fatal to the rodents in question, is perfectly harmless to human beings.

Messrs. R. A. Lister and Co., Limited, Dursley, displayed a most effective exhibit of well-made tubs, suitable for home and garden use, in a large and varied selection of artistic designs.

Messrs. Pilkington Brothers, Limited, St. Helens, Lancashire, had samples of their well-known cloches on view.

Robert Sydenham, Limited, Tenby Street, Birmingham, made a large display of rural table decorations in many new and choice designs, the whole being arranged in an artistic manner, setting forth the great advantage of this special form of table decoration.

Mr. James George of Putney showed his well-known specialities in horticultural sundries.

Messrs. Lawes Chemical Company, Limited, 59, Mark Lane, E.C., showed their well-known manures.

The Bon Arbour Chemical Company, Paterson, New Jersey, U.S.A., showed samples of their special goods.

Mr. Julius Hansen, Pinneberg, Hobstein, Germany, showed Lily of the Valley crowns, for which this house is noted.

Messrs. James Green and Nephew, Queen Victoria Street, E.C., had some excellent examples of their well-known glass and glazed ware, suitable for all horticultural purposes.

Messrs. Blake and Mackenzie, Limited, Islington, Liverpool, showed specimens of their paper pots, which are now in such great demand for raising seedling plants, &c.

The Elsenham Jam Company, Elsenham, Essex, showed specimens of their well-known jams and preserves.

The Boundary Chemical Company, Cranmer Street, Liverpool, were well to the fore with their various compounds for all garden purposes, a notable feature being the "Simplicitas" Sweet Pea trainer.

Messrs. William Cooper and Nephews, Berkhamsted, had several specialities, notably the celebrated V Fluids, both as insecticides and fungicides.

Messrs. H. Pattison and Co., Streatham, S.W., showed specimens of their lawn boots for horses in various sizes.

Messrs. Corry and Co., Shad Thames, E.C., showed to advantage their well-known goods, especially the famous "Niquas" and "Summer Cloud" shading.

Messrs. E. A. White, Limited, Beltring, Paddock Wood, Kent, had the latest examples and

improvements in their well-known syringe on view, together with "Abol" insecticide.

The One and All Agricultural and Horticultural Association of 92, Long Acre showed garden seeds and fertilisers.

Mr. G. H. Richards, 234, Borough High Street, London, S.E., had a representative exhibit of the latest and most up-to-date garden sundries and appliances, including insecticides and manures of the renowned "XL All" brand.

Messrs. Robinson Brothers, Limited, West Bromwich, had their "Guaranteed Gardenalities" well to the fore. Among these were "Carmona" Fertiliser and Clift's Fluid, a soil steriliser and germicide.

The French Cloche Company, Caxton House, Westminster, had their well-known cloches, special seeds for intensive culture, and other French gardening requisites on view.

Messrs. Barr and Sons, King Street, Covent Garden, showed the Pinozone Magazine Sprayer, together with Pinozone Essence, which destroys all microbes and germs and is non-poisonous and non-injurious, together with "Phytobroma" and other garden requisites.

The Sanitas Company, Limited, showed their well-known disinfecting fluid.

Mr. Arthur E. Hawker, Mark Lane, E.C., showed Horticol, a most useful preparation for dressing seeds preparatory to sowing, which is a protection from birds and vermin.

Cirengol, a non-poisonous insecticide, was also shown as a remedy for green fly and other garden pests.

Messrs. C. H. Glover and Co., Limited, Old Kent Road, had examples of useful boxes suitable for packing fruit, flowers and other produce.

Messrs. J. Bentley, Limited, Hull, showed their well-known weed-destroyer and fertilising compound.

Mr. F. C. Edwards, Leeds, showed sundries of various descriptions.

Plant Plantoids, 5, Lloyd's Avenue, E.C., the most recently-formed manure and plant food in tablet form, was on view.

Price's Patent Candle Company, Limited, showed the well-known Gishurst Compound, a remedy for insect pests, and Gishurstine for waterproofing boots, &c.

Messrs. Alexander Cross and Sons, Hope Street, Glasgow, were exhibiting their well-known ant destroyer and clubicide.

Mr. John Groom, Seckforde Street, showed artificial flowers of excellent quality and design.

Messrs. Jeyes, Limited, Cannon Street, E.C., had examples of their sprayers and spray fluids on view.

Mr. A. C. Harris, Leicester, showed that useful little article, the "Gripper" garden tool, and also the lawn-mower rabbit-cage.

The Halliford French Garden of Shepperton, Middlesex, showed French garden goods and produce.

Messrs. Lewis Berger and Sons, Homerton, N.E., had several examples of specially-prepared compounds for horticultural use.

Messrs. Merryweather and Sons, Greenwich and Long Acre, the well-known fire-engine manufacturers, had the entire fire protection arrangements placed in their hands, a number of hand fire-pumps and chemical extinguishers being on the ground, with men on duty ready for promptly checking any outbreak that might have occurred.

Messrs. Walter Voss and Co., Glengall Road, Millwall, E., had a large and interesting display

of specialities for various garden purposes. Among these may be noted the Bordeaux-Arsenite wash, thus being a compound insecticide and fungicide, which is, therefore, applied at one operation. Another special preparation is a priming glaze, a preparation for dressing the freshly-cut surface of wounds, which prevents canker or other fungoid growths, and causes a quick and certain healing.

The Four Oaks Spraying Machine Company, Sutton Coldfield, Birmingham, had their noted sprayers and other specialities in many and varied forms.

The Patent Safety Ladder Company, Peterborough, had some excellent ladders in various sizes suitable for all purposes.

The Folding Span Light Company, Wexham Road, Slough, showed examples of their special span lights, illustrating the many uses to which these lights can be put.

Messrs. Wakely Brothers and Co., Bankside, London, S.E., had their well-known Hop Manure to the fore. This is the most perfect substitute for stable manure yet to be obtained, and is clean and sweet to use.

Messrs. James Carter and Co., Raynes Park, had an excellent model of the new buildings at Raynes Park; they also staged an interesting feature of seed testing and germination as carried out by them.

In the Orchid Tent, Mr Edward White, 7, Victoria Street, S.W., showed a model garden designed for C Dyson Perrin Esq., Ardross Castle Ross-shire, consisting of castle and broad terrace leading to the sunk garden, followed by a formal design thence to an ornamental fish-pond, rock and water garden, and a general arrangement of effective and artistic planting.

Clay's Fertilizer, the standard plant food, was used throughout the gardens and grounds of the exhibition.

Nesting-boxes were shown by the Royal Society for the Protection of Birds, the offices of which are situated at 23, Queen Anne's Gate, Westminster, S.W.

BOOKS.

La Vie a la Campagne.—This interesting French publication devotes a considerable amount of space to the horticultural art, both practical and theoretical. The artistic also receives consideration, and in the last number to hand (March 15) we find a vast amount of information by Messrs. Maumené, Gibault and Lambert on the subject of decoration in ancient gardens. Beside the text there are nearly two hundred views of old gardens and garden accessories. Statuary, vases, fountains, sundials, pergolas, seats and benches, cascades, and innumerable designs and devices for the ornamentation of gardens are given in great profusion. The collection of so much interesting matter must have occupied the writers for a considerable time, and they are to be congratulated on presenting it to their readers in so attractive a form.

Vines and Vine Culture.—It is with feelings of the deepest satisfaction we see lying before us a fifth edition of this really famous book, with which the name of an old and highly-esteemed friend and a great gardener, Archibald F. Barron, is so closely associated. To his widow, Mrs. Barron,

the work of revising the earlier editions, so as to make the new and present one fully up to date, must have been a labour of love. In that labour she has had the assistance of some of her late husband's devoted friends, and secured from other sources new matter and some fresh illustrations, including bunches of Grapes, all of which add both interest and charm to the book. Unlike some of the would-be instructors of to-day, Mr. Barron was not a great book-writer. This one work on the Vine as it exists, is grown, and now presented will be a garden classic when myriads of the fugitive compilations called books to-day have disappeared. It was Mr. Barron's remarkable fidelity to truth, his energy in obtaining exact information, and, above all, his unrivalled opportunities at the old gardens of the Royal Horticultural Society, Chiswick, where almost every Grape named in the book was grown for trial in some one or other of the houses, that enabled him to acquire information relating to Vines not open to others to obtain. If many years of his life were spent in getting into shape all this information, the present generation of Vine-growers can utilise it to its utmost value if they secure this new edition. We specially rejoice that the revisers have, in their descriptions of Vines, so thoroughly brought the list up to date. New Vines come slowly, happily, and since the 1802 edition there have come into commerce to add to the long list of varieties Diamond Jubilee, Lady Hastings, Melton Constable, Directeur Tisserand and Prince of Wales, of house Grapes; and Gamay Noir, the French wine Grape, and Reine Olga, the red wall Grape, as outdoor varieties. Of the bunch illustrations, new ones are Muscat Champion, Prince of Wales and Syrian, each one good. These are supplemented by several garden decorative Vines of the new or Chinese species, an entirely new chapter devoted to the descriptions of ornamental Vitis being added. We welcome the retention of the picture of the old span vinery at Chiswick, one of the most remarkable vineries ever seen. In that house Mr. Barron found a wealth of material for study. It has long since disappeared, and, like the baseless fabric of a vision, left not a wreck behind. Still also is retained the picture of the great vinery at Cumberland Lodge, Windsor Park. That picture shows it to us as it was many years since, and in its old habitation. Under Mr. Mackellar's régime all is changed. The old vinery and its brick flues have disappeared, a new house has been erected, and the grand old Vine is now in a condition of almost youthful vigour. We could well have wished that, in a book which is to be handed down to posterity as the great Vine book of this age, the text descriptive of the wonderful old Vine at Hampton Court had been brought up to date. That veteran now has a new house larger than its old one. It is in quite robust health, really a marvel considering it has been planted for some one hundred and fifty years. Each year it carries from 250 to 300 bunches of Black Hamburg Grapes that are so superbly finished and coloured as to be very difficult to excel. It has had a marvellous recovery from the weakness of old age, as has the Cumberland Lodge Vine. We would like to learn that so great was the demand for this most reliable and valuable book that the new edition was soon exhausted. Young gardeners who may wish to know of authoritative or reliable books may be assured they will find one in Archibald Barron's "Vines and Vine Culture." —D.

EDITORIAL NOTICES.

Every department of horticulture is represented in **THE GARDEN**, and the Editor invites readers to send in questions relating to matters upon which they wish expert advice.

The Editor welcomes photographs, articles and notes, but he will not be responsible for their safe return. All reasonable care, however, will be taken, and where stamps are enclosed, he will endeavour to return non-accepted contributions.

As regards photographs, if payment be desired, the Editor asks that the price required for reproduction be plainly stated. It must be distinctly understood that only the actual photographer or owner of the copyright will be treated with.

The Editor will not be responsible for the return of artistic or literary contributions which he may not be able to use, and the receipt of a proof must not be taken as evidence that an article is accepted. Publication in **THE GARDEN** will alone be recognised as acceptance.

Offices: 20, Tavistock Street, Covent Garden, W.C.

NOTES OF THE WEEK.

Rosa sinica anemonæflora.—This is particularly fine this season with its large silvery pink flowers. It is hardy, and does well when grown up tree stems and on the pergola. It is beautiful for cutting and table decoration. *Rosa L'idéale* is likewise a lovely early Rose and such a delightful colour; it is exquisite for cutting when grown on a wall.

Rosa altaica.—The variety *spinosissima* is a fine single early white for the shrubbery or Rose walk. This, the earliest of its section and being so hardy, is worth the attention of all lovers of our national flower. *Rosa sericea* and *R. s. pteracantha* are both useful and interesting four-petalled Roses of an early character, the latter having large scarlet, transparent thorns, which are pretty when the sun shines upon them.

The Chinese form of *Primula sikkimensis*.—This is one of the attractive plants which have delighted visitors to the beautiful rock garden at Kew, which has been looking very well this year, although the reconstruction which has been effected has prevented some plants from attaining their full development as yet. This Chinese variety of the Sikkim Cowslip is a more handsome plant, with larger flowers than those of its kinswoman, but apparently more closely clustered. They are of the same pleasing shade of yellow, and this Chinese form appears as if it would have a future before it, seeing that it also looks rather taller than *P. sikkimensis* as we usually grow it.

***Primula pulverulenta* Mrs. R. V. Berkeley.**—Lovers of the hardy *Primulas* could not have failed to admire this plant as shown by Messrs. James Veitch and Sons at the International Horticultural Exhibition. Those who observed it were practically unanimous in agreeing that it was one of the best of the new hardy plants in the exhibition, and that was saying a good deal. Its handsome stems, mealy, like those of *P. pulverulenta*, bore fine whorls of white flowers, touched with crimson at the base. If a pure seedling of *P. pulverulenta*, it shows the close relationship existing between that plant and *P. japonica*, as the whole plant bears an unusually strong resemblance to a white *P. japonica*, though in a glorified form.

***Pinguicula grandiflora*.**—Few people seem to grow the large-flowered Butterwort, although it is by no means a difficult subject where there is a moist spot in the garden, such as that in which *Primula rosea* will flourish. Even our native Butterwort (*Pinguicula vulgaris*) looks pretty in such a place with its violet flowers, but it is eclipsed in beauty by its ally, which has larger and brighter-coloured blue flowers. A nice group of this appeared in one of the rock gardens at the Chelsea exhibition, but it did not attract the attention it

deserved as a good group of a plant little met with in the rock garden of the present time. The fact of its loving a moist bog will commend it to those who are making a feature of a water and bog garden, and who wish to choose plants not too large and possessing all the charms of the finest of the alpine flowers.

Beauty of the Rocks.—This is the popular and well-deserved name given to *Draba pyrenaica*, a charming little alpine plant, native of the Pyrenees, and often called *Petrocallis pyrenaica*. It requires a very gritty soil, and thrives when packed between small stones, such as one would provide in a moraine garden. The flowers, rosy lilac in colour, are produced throughout the spring months.

National Hardy Plant Society.—The first exhibition of hardy plants and flowers under the auspices of the above society will take place in the Royal Horticultural Hall, Vincent Square, Westminster, on Wednesday, June 19. In addition to the classes set forth in the schedule, we learn that Messrs. Sutton and Sons are offering prizes for six bunches of Sweet Williams, both pink and scarlet. All communications respecting the show should be addressed to Mr. A. J. Macself, 52, Beechfield Road, Finsbury Park, London, N.

Tulipa Sprengeri.—This is still the latest of the Tulips to flower, and it comes in very usefully and pleasingly after the Darwins and other late flowers are over. It has not yet, apparently, given us a variety of colour, but the rich orange scarlet flowers with golden anthers are bright and showy. Probably it will some day prove the parent of a late-flowering race of Tulips, which would prolong the succession for a considerable time after the others had passed away. Sprenger's Tulip is about one and a-half feet high, and has the flowers of good size for the stature of the plant. It seems to be thoroughly hardy, though not increasing much by offsets, and flowers annually on rockwork and in the border.

An Uncommon Arrangement.—An exhibit in the big tent at the recent International Horticultural Exhibition at Chelsea, which attracted a good deal of attention from its unorthodox character, was an arrangement of *Statice profusa* and *Malmaison Carnations* from Mr. Leopold de Rothschild's garden at Ascott, Leighton Buzzard. The groundwork consisted entirely of dwarf, well-flowered examples of *Statice profusa* disposed rather thickly. Springing from this groundwork were fine clumps, each consisting of several plants, of three or four varieties of *Malmaison Carnations*, among which that popular variety, Princess of Wales, was very noticeable. The bed, in shape somewhat like an elongated crescent, was edged with *Isolepis gracilis*, a charming subject for such a purpose, though not used now to the same extent as it was at one time.

CORRESPONDENCE.

(The Editor is not responsible for the opinions expressed by correspondents.)

Narcissus Poetaz Orient.—I can endorse all that the Rev. J. Jacob says about this variety. It is a most charming flower to grow in pots, and is a wonderful laster.—H. G. H.

Rosa Hugonis.—This Rose has been very early with me this year; in fact, so early that the frost has destroyed quite half of the shoots, which were covered with buds, and I am afraid they will not break again. Is it supposed to be quite hardy? I have had it in my garden three or four years, and it has not before been affected by frost.—H. G. H., *Strode*.

Euphorbia Wulfeni.—I enclose a photograph of *Euphorbia Wulfeni*, which may interest your readers if you care to reproduce it in *THE GARDEN*. I have had it for four years, and this is the first time it has bloomed, and of the 2,500 different plants in my collection, none has caused greater interest and surprise to the hundreds of visitors who avail themselves of the opportunity of inspecting my alpine and herbaceous garden. There are no less than twelve spikes of bloom open.—ALBERT WOOD, *Sutton Coldfield*. [This interesting Spurge has been the subject of much correspondence in our pages. An illustration appeared in *THE GARDEN*, January 22, 1910. Unfortunately, the photograph sent by our correspondent is not suitable for reproduction.—En.]

Choisya ternata.—On page 250, issue May 25, of *THE GARDEN*, "A. D., Kingston," has a note on this plant as grown in the public gardens there, and expresses surprise at seeing such a fine specimen and its apparent hardness. I am quite sure that many readers would be similarly surprised, as it is regarded as a shrub only suitable for growing outside in very sheltered positions. If grown in firm, suitable soil, however, *Choisya ternata* will succeed in any open border in gardens south of the Midlands. Twenty-five years ago I had a cutting given me, which was rooted in due course and planted outside in a partially-sheltered position. The roots grew mainly under a path which was traversed more than any other in the garden, so that the rooting medium was a very firm one and not at all rich. In seven years the bush had grown many feet through and 5 feet high. It is a great specimen at the present time, notwithstanding the severe and frequent cutting back of the branches. It has flowered profusely, and never suffered in the least from frosts in that long period. It certainly deserves to be more extensively grown as a hardy flowering shrub than at the present time.—G. G.

— I venture to think this beautiful shrub is much more hardy than your correspondent, "A. D., Kingston" (page 250, issue May 25), seems to think. My garden is situated in a bleak spot in Cheshire, 250 feet above sea-level, exposed to heavy gales from the Irish Sea, and yet this evergreen blooms more or less every year, and is at present covered with bloom, although we had 20° of frost last winter. It is true we place mats round it in winter. It is 4 feet high and 5 feet through. I have another plant about half the size, and we have no difficulty in striking cuttings from it. I fancy there is too much hesitation in trying supposed tender evergreens in the North of England. For instance, *Olearia Haastii*, which Robinson says may thrive in favoured spots in the South, thrives in this neighbourhood, and never fails to bloom profusely

every year without any winter protection. I have more than a score of plants 3 feet and 4 feet high and 4 feet through. Even *Olearia dentata*, which is certainly more tender, has grown with me 5 feet high, and is covered with bloom in July. *Enrybia Gunnii* is more uncertain, though it has survived the winter, and is now blooming on all the points not cut by the frost.—S. A. D., *Noctorum*.

Geranium Hall Caine.—This variety is very showy and well worthy of special mention. The colour is salmon, and the inflorescences are borne freely on a bold, long axis. The individual flowers often measure 2 inches across and possess qualities of a very lasting nature; moreover, the foliage is large and ornamental, having a noticeable brown zone that is deepened by the application of soot-water. In my judgment it is one of the best *Geraniums* extant for greenhouse decoration.—GEORGE H. COPLEY, *Horton Park, Bradford*.

Manures to Deepen the Colour of Roses.—With reference to the paragraph on the third page (251), signed "P.," of *THE GARDEN* for May 25, I may mention that sulphate of iron (greenstone) has been found to effect this, as also to strengthen the scent. When in India, at Almera, Kumaon, U.P., in the early seventies, I used to experiment a little in this way, planting ten Roses of a similar variety in a row, separated from each other, and feeding them with different manures—burnt brick, sulphate of iron, horse, cow, goat, sheep, rabbit and poultry manure. The sulphate of iron always brought out a fuller and richer colour and scent, while the animal manures brought on the foliage. Wakeley's Hop Manure has a similar effect, deepening the colour of Roses, and also helps the plant generally. I got the idea of experimenting with manures from a manual on Indian gardening by a Madras Army officer whose name I have now forgotten.—H. G. BATTEN, F.R.H.S., F.N.R.S.

Horticultural State Honours.—It is greatly to be hoped that the honour of knighthood so fitly and so aptly conferred by His Majesty the King on Mr. Harry J. Veitch is but the prelude to others that may well be merited. Horticulture, so far, in its relations to the State does not seem to have obtained in the past the high position it deserves. There have been knighthoods given for distinguished botanical service; and, indeed, the one which pleased us all, the granting of that honour to Sir F. W. Moore of Glasnevin, was awarded more for botanical research than for horticultural status. But Mr. Veitch is a thorough horticulturist. Apart from being the head of the greatest nursery establishment in the kingdom, he is far more widely known as a great gardener and as a friend of gardeners; hence that widespread approval heard and the pleasure given. But the announcement made by Mr. Runciman at the jurors' luncheon of a probable intention on the part of the Board of Agriculture to establish a horticultural diploma opens up a wide prospect both of honours and of anticipations. But to myriads of great and good gardeners there is a large fly in that State pot of ointment. It is in the form of examination tests which seem to be foreshadowed. Other than the splendid work they have been doing for horticulture all their lives, what better test is needed as to the merits or fitness of those able men, many of whom have passed into the serene and yellow leaf of life and could not pass a paper examination as young, inexperienced, but well coached, students can? Fancy putting to the test of a paper examination

on Orchid culture the grower of that magnificent group of Orchids staged at the great show from Westonbirt! Who will test the knowledge in fruit culture of those great gardeners who figured so finely also at that show? To attempt any such test would be utterly absurd. If a State diploma be established, awards must be made on the basis of work done rather than on a written test. In the case of young candidates who have so far no work to show, their admission to the diploma must be only after severe examination tests—first, scientific, and, second, practical. A wide knowledge of entomology and mildews is most valuable; but the good, capable cultivator who fights these enemies with high-class culture and good treatment is generally the better gardener. There are other ways, however, than through the State that honours may be given to men who have done good work in gardening. Sir George Holford at the jurors' luncheon illustrated that method in the public way he complimented his able Orchid-grower, Mr. H. G. Alexander. Why should that incident be so singular? How few great employers, gentlemen or traders, have previously done so much, and yet pages of *THE GARDEN* could be filled with the names of men who in private work and in trade have rendered to horticulture magnificent service; indeed, it is they by their skill, their industry and hard labours who have made our beloved vocation what it is. What an army of these there are who have over and over again earned their proposed diplomas!—D.

Varieties of *Leptospermum scoparium*.—Although visitors to the recent Royal International Exhibition on the look-out for the more gorgeously-coloured subjects might have passed it over without notice, yet to many one of the most interesting exhibits in the large tent was a group of three distinct varieties of *Leptospermum scoparium*, shown by the Rev. A. T. Boscawen, Long Rock, Cornwall. The typical *Leptospermum scoparium* is a native of Australia and New Zealand, and in both cases it covers considerable tracts of country. In New Zealand, where it disputes the right of way with the common Bracken, it is said to vary in height from 1 foot to 20 feet, and during the flowering period from November to January it is very handsome, but when out of bloom the greyish green of its foliage forms a monotonous feature. In this country it is a delightful shrub for particularly favoured spots in the West, but throughout the greater part of England it can only be regarded as an ornamental subject for the greenhouse or conservatory. Botanically, it belongs to the same family as the Myrtle; but though the leaves have somewhat of the aromatic fragrance common to the genus, yet it is far less pronounced in this than in many others. The leaves have before now been sometimes used as a substitute for tea; indeed, this *Leptospermum* is often known as Captain Cook's Tea Plant. Of the three varieties above alluded to, the most striking is *Nichollii*, which was illustrated in *THE GARDEN*, page 264, and was given a first-class certificate by the floral committee. In this, instead of the flowers being white or nearly so, as in the typical kind, they are of an intense ruby red colour, a tint quite startling to one accustomed only to the light-coloured forms. The second variety, *Chapmannii*, is of more upright growth than the others, while the flowers are of a rosy red hue. In the third, *Boscawenii*, the plant is unusually loose and graceful in habit, while the comparatively large flowers are almost white with a red centre, the buds being bright red.—H. P.

Salvia splendens Pride of Zurich.—The day is not so very long past when *Salvia splendens* was chiefly regarded as a flowering subject for the embellishment of the greenhouse or conservatory during the autumn months. With the advent of some dwarfier forms, of which *Pride of Zurich* is one, this is all changed, and now for the last two or three years it has, at the meetings of the Royal Horticultural Society, figured among the spring flowers. At this season it is very bright and effective, but its greatest value is for bedding out during the summer months, at which time its brilliantly-coloured flowers form a notable feature. It is also of considerable service for greenhouse decoration. Seeds of some of the varieties are occasionally offered; but for freedom of flowering in a small state I much prefer to strike them from cuttings, which in a gentle heat will root in a very short time. My experience of seedlings is that they are more liable to run up during their earlier stages than those propagated from cuttings.

Shrubby Marigolds.—The immense Composite Order is freely represented in South Africa, of which continent the various species of *Arctotis*, or *Shrubby Marigolds*, are native. They were especial favourites of that enthusiastic plantsman, the late Mr. W. E. Gumbleton, whose collection contained some unique forms. As it is, they are difficult to obtain from nurseries, the most generally met with being *Arctotis aspera* and *A. aureola*. Of these I prefer the last-named, the flowers being about four inches across, with the spreading ray florets of a rich orange yellow colour. In *A. aspera* the florets are of a pale yellow or straw colour, with a deep yellow disc. The "Dictionary of Gardening" gives 1710 as the date of the introduction of both of these species, yet, pretty though they are when in flower, they are rarely seen. The nomenclature of the entire genus is considerably involved, for in some cases at least authorities agree only to differ with regard to the correct names. Their cultural requirements are not exacting, as they need much the same treatment as a *Pelargonium*.—H. P.

A Little-Known Rock Garden

Plant.—The fine little plant *Erodium pelargonifolium* is but little noticed in horticultural works at the present time, and the question of its hardiness is worth some consideration, as it is now coming into bloom, and is one of the finest rock garden plants, with its white flowers prettily marked with purplish crimson. Both in flower and leaf it has a considerable resemblance to the old *Pelargoniums* which were so popular for growing under glass and are still prized by many. It is totally unlike the other *Erodiums*, and is a handsome rockery plant, making a good trailing bush of considerable effect and of much real beauty. It is, however, a

plant which requires some care with me, also with a considerable number of others who have tried it. It appears to require occasional propagation, either from seeds or from cuttings, and the latter method is the more convenient, as the seeds may be forgotten when ripe, while cuttings can be taken at practically any time in summer and strike easily, just as one would strike a *Zonal Pelargonium*. The difficulty lies in keeping old plants, as, while a young one will stand the winter well in most cases, a larger plant will die. It is, therefore, almost essential to keep a plant or two in a frame if *E. pelargonifolium* is not to be lost. It apparently delights in a warm, dry soil and a

SIR HARRY J. VEITCH, V.M.H.

THE honour of knighthood that has fallen to Mr. Harry Veitch is as popular as it is well deserved, for there is no man in the gardening fraternity more worthy or better fitted to adorn the rank to which he has been called. His energies towards the success of the recent International Exhibition are well known, and merit the sincere thanks of all horticulturists and thousands besides. The honour is more than a personal one, for it is a tribute to British horticulture and a fitting commemoration to an eventful year. Sir Harry's long association with the advancement of horticulture in this country is a matter for general admiration, and his experience of International exhibitions is unique. When it was determined to hold the great International Horticultural Exhibition in 1866 in London, he entered with zest into the work as one of the general committee. At the Continental gatherings during the past forty years or so, Sir Harry has been a constant visitor, and it is of special interest at the present time to observe that he was present at the first International exhibition ever held in Russia, this occurring at St. Petersburg in the spring of 1869, when the party, among whom were Sir Joseph Hooker, Dr. Robert Hogg, Dr. Moore of Glasnevin and Mr. Robert Warner, were cordially welcomed by the Czar.

Sir Harry J. Veitch was born on June 29, 1840, at Exeter, and received his education at the Exeter Grammar School and in Germany. He afterwards attended the course of botanical lectures given by Dr. Lindley at the University College, and gained an insight into the working of the seed department of the business which he was soon to manage in the establishment of Messrs. Vilmorin at Paris. Sir Harry is known for his splendid business capacity and his untiring energy in promoting good work. It is well over fifty years ago since he commenced his duties in the Chelsea nurseries, and to-day throughout the world wherever horticulture has gained the affections of the people the name of Veitch is honoured.

It seems almost unnecessary to write of his love and devotion to the Gardeners' Royal Benevolent Institution. Moreover, he is an active supporter of the Royal Gardeners' Orphan Fund, and has been closely associated with its good work from the commencement.

Many are the tokens of the esteem in which Sir Harry and Lady Veitch are held by those with whom, during a busy and happy life, they have been brought into contact. That they may live for many years to enjoy their well-deserved honour is the sincere wish of their numerous friends at home and abroad.

SIR HARRY J. VEITCH, V.M.H.

sunny place, where it soon attains some size and looks remarkably pretty.—S. ARNOTT.

FORTHCOMING EVENTS.

June 10.—United Horticultural Benefit and Provident Society's Committee Meeting.

June 12.—Royal Cornwall Show at Penzance (two days). East Anglian Horticultural Society's Meeting.

June 16.—Royal Horticultural Society's Meeting and *Gladiolus* Show. Lecture by the Rev. Professor Henslow on "Professor J. S. Henslow as Ecologist."

TREES AND SHRUBS.

HARDY SHRUBS WITH PEA-SHAPED FLOWERS.

I NEVER remember seeing the Wistarias quite so good as they have been this season. Even the old forms were larger and more beautiful than ever. Those growing on the mansion and on south walls and those trained up tripods were beautiful in the extreme. Some time since they were planted on a train over large trees, where they look most beautiful and are always effective. The frost in April took some of the blooms, but did not do much damage; it simply thinned them to make the remainder all the stronger. When associated with Laburnums they are glorious, and trained along the top of a high wall and the top fringed with the blooms it is really a marvellous sight. These plants like a little assistance when planted near large trees, and the roots of the trees should be kept as clear of them as possible. There are some marvellous specimens about the country, but they are very often in out-of-the-way places. My employer has told me that he knew of one fine plant which was nearly a quarter of a mile long, trained over the mansion and around all the garden walls. The newer variety, *multijuga*, has much longer racemes of flowers, and is very handsome.

The Brooms.—At this season the Brooms are very handsome garden subjects, especially *Cytisus præcox*, *C. p. alba* and *C. andrea*. Then there is the Madeira Broom, *C. virgatus*, which makes a fine tall plant and flowers later, generally at its best in June; this is an evergreen. *C. nigricans*, the summer-flowering type, flowers in July and August. Then the old common Broom, *C. scoparius*, is very fine in its season. *C. schipkaensis*, a dwarf grower, with creamy white flowers, is a fine dwarf plant and a good one when grafted on a stock 4 feet or 5 feet high. *C. kewense*, a dwarf, trailing variety raised at Kew, is very pretty and bears its creamy flowers freely in May. *C. Bearii*, with its bright yellow flowers, is also an attraction. *C. Ardoinii*, a very pretty species about four inches high, forms a mass of golden flowers in April.

Genistas.—*G. prostrata* is a very pretty and useful plant for bare spaces on account of its trailing and spreading habit, and only grows a few inches from the ground. *G. monosperma*, a rare species with white flowers, is inclined to be somewhat tender; this should always be planted in a warm and sheltered spot. *G. hispanica* is a rare free-flowering species and a good grower. *G. horrida* makes a fine plant, and has sharp-pointed leaves. *G. decumbens*, a very pretty trailing variety, is suitable for the alpine and rock garden.

G. tinctoria, a dwarf, compact, creeping plant, bears orange flowers in July and August. There are many more forms and varieties, but I have given enough to show their extreme usefulness.

The Rose Acacia (*Robinia hispida*).—This is among the most beautiful of all flowering trees and shrubs.

Cæsalpinia japonica is another most beautiful shrub.

The Honey Locust (*Gleditsia triacanthos*) is also very beautiful and well worth growing.

flowers. These trees, when used for planting extensively, are very effective. If used alternately with such trees as Copper Beech, *Prunus Pissardii* or trees of that character, a wonderful contrast of colour is produced. There are no trees capable of greater effect if planted in bold groups or by the hillside, water-side, park drive or avenue; in fact, one can scarcely plant these trees in the wrong place.

Desmodium penduliflorum is a very pretty Japanese shrub with wand-like, gracefully arching shoots which grow 5 feet to 6 feet long, and are clothed with large leaves and bear panicles of reddish purple, Pea-shaped flowers in August and September, when few shrubs are in flower.

W. A. COOK.

Leonardslee Gardens, Horsham.

SPRAY OF A BEAUTIFUL TREE (*EDWARDSIA GRANDIFLORA*) BELONGING TO THE PEA FAMILY.

Judas Tree (*Cercis Siliquastrum*) is a very old introduction and still one of the most lovely. It grows into a tree 30 feet high, and bears rosy purple flowers in great abundance along the branches before the leaves appear. It is in flower now and most attractive.

***Edwardsia grandiflora* (syn. *Sophora tetraptera*)** is a most beautiful plant for a wall, and few things are better. See illustration. Then we have the very handsome

Laburnums, which are particularly showy, to say the least, especially the variety *Vossii*, which has very long trusses of rich pale yellow

KITCHEN GARDEN.

SEASONABLE NOTES ON VEGETABLES.

Scarlet Runners.—This is one of the most important crops of the vegetable garden, but its full value is not usually appreciated until the bulk of the Green Peas are passing, or have passed, their best. With a view to ensuring heavy crops on plants full of vigour late in the season, the seeds ought not to be sown at the middle of May, or even earlier, as many amateurs do, but during the first week of the present month. The soil is warm, and it can easily be made pleasantly moist, if it is not in that condition naturally; there is no danger of late frosts causing a more or less severe check; and the plants, therefore, have every inducement to go straight ahead to profitable bearing. It is necessary to provide a rooting medium which is at once deep and in excellent heart, and the seeds ought to be set at distances varying from 5 inches to 12 inches asunder, according to the variety, on a firm, level base about two inches beneath the surface of the ground. At the end of each line have a clump of a dozen seeds or so, from which plants can be drawn to fill gaps that may occur in the rows. Abundance of space goes for excellence of quality, bulk of crop and longevity of production in the plants.

Outdoor Tomatoes.—One would hesitate to recommend the planting of Tomatoes in the open quarters of many gardens for a week or ten days yet; but when they are intended for positions against warm walls or fences, the sooner the work can be done the better. It is then by no means difficult to provide protection, should the necessity for it arise, but this cannot always be managed in the open garden. In either case it is essential that the soil shall be in perfect mechanical condition, and that it shall contain readily available food; but the incorporation of fresh manure must be done with great judgment, or the plant

will rush to leaf growth at the expense of flower and fruit production. It is much wiser to give a really good, plain soil to start with, and feed as may be deemed wise or desirable when the roots are properly established. Each plant for outdoors should carry a truss of fruit and a truss of flowers when the planting is done to ensure the best returns.

Plants in Seed-Beds.—There will be a few thousands of plants in seed and nursery beds just now, and it is essential to the successful cropping of the garden in the winter that these youngsters have every inducement to make strong, sturdy, stocky growth. To allow them to become so crowded that they grow up into leggy, ungainly examples is an error that positively must be avoided, since such specimens can never make splendidly profitable plants when the call is on them next winter and spring. Therefore thin them out and transplant them to other positions immediately they demand more space, and see to it that they never suffer through lack of food owing to the soil about their roots becoming as dry as dust. No weeds ought to be tolerated in the seed or nursery beds, because they rob the plants of light and air as well as food.

Vegetable Marrows.—These ought to be placed in their permanent positions as soon as possible, as they demand a considerable time to grow into the fruiting stage. They are often put on heaps of soil or manure, and provided they do not grow too rampantly, they then occupy places where nothing else would crop. Or a hole can be taken out, filled with manure and surfaced with a good dressing of sweet soil, and the planting can be done on the slightly-raised summit. The bush varieties should be far more extensively grown in small gardens, as they bear magnificently and do not demand a serious amount of space. Seeds pressed into the soil now, if it is fertile and in good condition, will grow and fruit well in due course.

Hoing.—The Dutch or draw hoe ought to be incessantly at work in the vegetable quarters from now onwards to the end of the growing season, and those who neglect it may rest assured that they will lose a substantial proportion of the value of the food which has been worked into the ground for the benefit of their crops. It is impossible to hoe too much, never, of course, attempting it

ROCK GARDEN EXHIBITED BY MR. MAURICE PRICHARD AT THE RECENT INTERNATIONAL SHOW.

when the surface is wet. Weeds not cut out by the hoe must be removed by hand. H. J.

THE ROCK AND WATER GARDEN.

ALYSSUMS IN THE SPRING GARDEN.

THE genus *Alyssum* embraces a group of plants that combine beauty and utility in a marked degree and are more or less indispensable in every garden. The colour range is restricted to yellow, as those having white flowers are not important enough from the garden aspect to merit attention. Curiously enough, this genus supplies a colour deficient in *Aubrietia* and *Arabis*, with which it is commonly employed in the rock garden; hence it is apparent how important *Alyssums* become in this floral tripod. Although chiefly alpine in character, *Alyssums* readily adapt themselves to ordinary conditions in gardens, always succeeding best in hot, sunny exposures such as the rock garden offers; they are also most satisfactory subjects for dry walls, where the growths have every opportunity of becoming ripened under the concentrated power of the sun's heat. They are not particular as to soil, provided it is light, well drained and contains a fair percentage of lime, as under these conditions growth is always

most satisfactory and the floral display is well assured.

Propagation.—All the species and varieties are easily propagated by seed or cuttings. The former may be sown as soon as ripe, or may be deferred till spring, using shallow pans and sandy soil, transplanting the seedlings into pots or boxes when large enough to handle. Artificial heat is never necessary. An ordinary greenhouse in which to germinate the seed and an unheated frame in which to stand the seedlings are valuable aids towards early propagation, although equally good results may be obtained by sowing late in an ordinary garden frame. *Alyssum saxatile* and its lemon-coloured form are both largely employed in spring bedding arrangements, and where a large quantity is required it will often be much simpler to dispense with pots and transplant the seedlings direct into boxes, afterwards transferring to a nursery bed in the open. If carefully lifted in autumn, little or no check is occasioned the plants, as owing to double transplanting in the early stages an excellent fibrous root system is developed.

Cuttings may be used with equal success. They are best taken when the current season's wood begins to harden, towards the end of June or early July. The cuttings are inserted in sandy soil in a hand-frame and kept close till such time as roots are formed, afterwards transplanting to pots or boxes, as is most convenient.

The Best for the Garden.—*A. saxatile* is the best-known species. It makes a vigorous, rounded bush up to 18 inches in height. The flowers are borne in close, branching beads of a rich buttercup yellow, and are produced in the greatest profusion, so that even a single plant becomes a most conspicuous object when in flower. The leaves are lanceolate, entire and of a hoary grey green, while the stems are woody at the base. Of this species there is a double form, dwarfier than the type, with flowers resembling small double rosettes. It is a first-rate rock plant, and remains in flower from April till June. The variety *citrinum* is one of the most effective colours in the spring garden, the flowers being of a delicate lemon or sulphur tint. In other respects it resembles the type. There is also a form having the foliage prettily variegated with creamy white, the colouring being best developed when planted in full sun. It is most useful for contrast, and is greatly favoured in carpet-bedding and similar arrangements. *A. alpestre* is a typical alpine species, forming neat, rounded tufts of hoary leafage that in May and

MR. J. WOOD'S ROCK GARDEN FROM BOSTON SPA AT THE INTERNATIONAL SHOW.

June become almost hidden by the wealth of rich yellow flowers that burst from the tiny stems. It is a dwarf subject, and rarely exceeds 3 inches in height.

A. montanum is more prostrate in habit than the last-named species. The stems and leaves are hoary green, the former terminating in simple racemes of bright yellow flowers that are freely produced in May and June. This and the previous-named species are ideal plants for any old wall, as if once established they live to a great age, never failing to flower in their appointed season.

Coombe Court Gardens. THOMAS SMITH.

THE DRIPPING WELL AT KEW.

VISITORS to Kew Gardens on passing through the rock garden cannot fail to notice the dripping well. It is a cool retreat, suitably furnished with rock and water-side plants. A slight fall of water

THE ROSE GARDEN.

ROSE BLANC DOUBLE DE COUBERT.

THIS charming Rose is ever welcome, for it is the first to yield its blooms, which are quite dazzling in their snowy purity. I had a fine standard of it on May 29 in full bloom, and near by are arches of Carmine Pillar just unfolding, which tend to accentuate the pure whiteness of the rugosa Rose. To see this Rose in perfection one must grow it as single bushes or on standards and half-standards, but it also makes a fine hedge. I admire the Blanc Double de Coubert more than the single white, although this latter is very beautiful, and, of course, has the good quality of giving us fine showy fruits in the autumn, which Blanc

charming Roses that possess so weak a constitution that they cannot fail to disappoint the average grower who is not aiming for one or two flowers only. Of course, with the vast number of varieties now grown, no catalogue or list can give much fuller descriptions than at present, and we can scarcely expect the vendor to lay any emphasis upon qualities not eminently desirable.

It is my purpose to note a few of the varieties I could not recommend to any small amateur grower. No elaborate description of the bloom itself comes within the province of this article, and while I by no means wish to malign the varieties, it is well to know a little more of their characteristics of growth and flowering. Duchess of Bedford is a grand Rose for the exhibitor, especially when he can afford to bud his own Briar stocks and cut from maiden plants. But I find it by no means a good Rose to transplant, and in most places it is weak and short-lived after the first season. Gustave Piganeau, Alfred K. Williams, Comtesse de Ludre, Louis van Houtte, Reynolds Hole and Xavier Olibo are other truly beautiful Roses among the Hybrid Perpetual class that have much the same characteristics as Duchess of Bedford.

Another class of growth is found in the same section that, while not dwindling away in a similar manner, are usually too short and stumpy in growth to please. Nor can a short, stumpy growth possibly produce any quantity of flowers, and there can be little object for the small grower to have either of those named when there are numbers of good growers and free bloomers closely resembling them in all other respects. I will name Etienne Levet, Ulster, Marie Verdier, Marchioness of Downshire and Merveille de Lyon as examples.

Roses with Slender Stems.—Yet a third class can be taken from the Hybrid Perpetuals, and they are those with a persistent drooping habit, and generally carrying heavy flowers upon stalks and growths far too slender to support such a burden. Consequently, one has to expend a lot of time in tying up the growths, or the blooms are entirely spoiled by earth splashing. Earl of Dufferin cannot be dispensed with in a large collection, but the buds are of immense size and substance, needing a long time to develop. I have frequently had it extra good during a warm season; but it always droops and is of little service unless great care be taken, and then only when cut and the flower supported in some way. Gloire de Margottin, Camille Bernardin and Marie Baumann are further examples. The only phase of culture suitable for a drooping flower is upon tall standards, pillars and walls. Then one can see into the depth of the flower; but, unfortunately, this habit of drooping means much greater attention in culture. Hitherto the Hybrid Perpetual section is the only one dealt with, but other sections possess varieties with precisely the same undesirable characteristics. To take the Teas and Noisettes first, I will name a few that are constitutionally too weak to throw many flowers, and so generally die out, to the bitter disappointment

AN ESTABLISHED DRIPPING WELL IN THE ROCK GARDEN.

trickles down between the rocks and collects in a pool, whence it takes the form of a little stream. As may be seen from the illustration, this stream serves to supply such plants as Wood Lilies (*Trilliums*) and Globe Flowers (*Trollius*), both of which are in flower, with the requisite amount of water. The surrounding rocks are suitably planted with ferns and Saxifrages, while hold clumps of the perennial Candytuft (*Iberis sempervirens*) create a fine display all through May and in early June. At no time is this delightful spot devoid of interest, and it is here, in damp but well-drained soil, that Soldanella—the daintiest of all alpine plants—looks almost as happy as it does in its mountain home. It might here be mentioned that the whole rock garden at Kew is so constructed as to appear like the rocky course of a mountain stream. Such streams often dry up in winter, and are bounded by rock-piled banks, amid the crevices of which a copious summer vegetation springs up.

Double de Coubert does not. I would suggest to anyone who would like a good contrasting bed of Roses for early June flowering to plant this variety as half-standards, with the crimson Mrs. Anthony Waterer beneath. Such a bed well isolated would be a most beautiful feature in any garden.

ROSES UNSUITABLE FOR SMALL GROWERS.

UNFORTUNATELY, we have several varieties of Roses—and these among the most beautiful as individual blooms—that are decidedly unsuited for the grower with little space or cash. I do not think there is enough note made of this suitability or otherwise, and far too often the flower itself is dwelt upon minus any definite remarks about its adaptability to the needs of the small grower. Some Roses are certainly more shy-blooming than others, even when grown by the most experienced. Then, again, there are not a few

of the small grower, who has probably obtained the variety after seeing a grand specimen in the exhibitor's box. I remember the glorious flower of Cleopatra exhibited at Windsor many years ago. The reverend gentleman who grew it noticed me taking its dimensions, and, after seeing how surprised I was, told me he thought I should be even more surprised if I could see the plant (?) he cut it from, for, said he, "that is all there was of it!" As a rule, Cleopatra is small and with long buds. Of course, the plant alluded to was thinned out to one bud only, and, being upon an extra vigorous growth for this variety, gave an abnormal bloom.

But few small growers can afford to grow upon these lines. Mme. Cusin, Mme. de Watteville, Golden Gate, Ma Capucine and Niphotos are others that may be classed with these. The thinner and softer petals among the Teas and Noisettes often make the blooms difficult to open, the petals rotting before the centre has developed. Jean Ducher and Etoile de Lyon are examples.

Among the newer section of Hybrid Teas we find several that are only fit for the exhibitor's box, and then solely when a large number of distinct varieties are wanted. Lady Mary Fitzwilliam, Mildred Grant and White Lady certainly produce wonderful flowers, but there are so few of them and they are bad growers. Others in this section that I cannot recommend for general culture are Bessie Brown, Queen of Spain and Ernest Metz. Neither can be relied on. A. P.

ROSE MME. MAURICE DE LUZE.

It is not many of our present-day novelties that can truly be claimed by the exhibitor as well as by those who desire to decorate their gardens. But such is the case with the Rose illustrated herewith. Without a doubt it is one of the best M. Pernet-Ducher has given us, and this is saying a good deal. Its large, deep rose pink blooms have a wonderfully clear hue about them, and this is much accentuated by the beautiful bold petals—like huge shells. Then, too, the fragrance is delightful, of that unctuous sort that is so refreshing. It is a bushy grower, not rampant, but compact, and it would make a nice, even bedder, one that would yield plenty of superb blooms upon good, erect growths. M. Pernet-Ducher in 1907 sent out three really fine novelties, one of them the above-named Rose, one Laurent Carle, and the third Mrs. Aaron Ward, and all three have established themselves quite securely in our collections. P.

THE FLOWER GARDEN.

THE VIOLETTAS.

[See coloured cover.]

THESE miniature-flowered Tufted Pansies are essentially plants for the rock garden, where, provided good soil and an adequate amount of free root run are assured, they invariably do very well. To the late Dr. Charles Stuart of Chirnside, N.B., belongs the credit of having raised the first Violettas. In 1874 he succeeded in crossing Pansy Blue King

SWEET PEA NOTES.

Vases for Exhibiting.—If the stock of vases which will be required for the fast approaching show season has not yet been overhauled, it is imperative that it shall be put in hand forthwith. It is inevitable that a few will be broken or lost each season, and nothing is more irritating when one is putting together the many things for an exhibition than to find that there is a shortage of vases—one might almost as well find one's self short of excellent flowers. Many growers adhere

strictly to a particular pattern of vase, and the system has much to commend it, since one knows precisely what is wanted to fill it to the best effect. It may, however, cause more than ordinary trouble, because one seldom lives within a stone's throw of the emporium from which the chosen pattern can be purchased; hence the paramount importance of a close inspection of all in hand a few weeks before the actual time of use, as one can then easily procure the requisite new ones to complete the set and leave a few over for casualties.

Material for Shading.—

Perhaps what is known as butter muslin is the most popular of all materials for this purpose; but whatever may be utilised must be inspected at once with a view to seeing whether there is sufficient in hand for the season, and if it is in sound condition. The work of examination will not occupy many moments, and if it is ascertained that the quantity is short or that the material is worn out, a supply ought at once to be procured. A safe rule is to buy enough to shade all varieties in which orange shows in the colour, although we know from interested descriptions that none of these now burns, and to have some over in case it should be deemed wise to protect scarlets, crimsons and other shades susceptible to injury by the sun.

Boxes for Packing.—These are another commodity with which the exhibitor must make absolutely certain that he is fully equipped. Old hands in the show arena know, often from painful and expensive personal experience, how dangerous it is to rest content in the idea that any boxes will answer the purpose, and that there must be plenty lying about the place ready to be picked up the second they are wanted. The man who desires or determines to be on the safe side will turn out all the boxes that can be found, put on one side those that are in suitable condition and have properly-fitting lids, and throw the remainder away

A BEAUTIFUL HYBRID TEA BEDDING ROSE MMÉ. MAURICE DE LUZE.

with Viola cornuta of the Pyrenees, and the progeny of this interesting cross gave us many most pleasing variations. In 1887, among a batch of seedlings, there appeared a lovely white blossom of miniature proportions and distinctly sweet-scented. This plant was named Violetta. Half-a-dozen good varieties are Lavinia (blush lavender), Gertrude Jekyll (rich yellow and primrose), Violetta, Diana (primrose), Eileen (blue), and Grace (pure white with neat yellow eye). All Violettas are rayless and sweet-scented. Rock Yellow is a more recently raised rich yellow sort. D. B. CRANE.

or use them for some other purpose. Then the selected ones will be again looked over, even more carefully than before, and, doubtful starters, will be instantly discarded and consideration given as to whether those which remain will answer all the demands that may be made upon them; if not, an additional supply will be bought at once.

Name Cards.—It is the rule at most exhibitions, though it is all too common to see it honoured in the breach rather than in the observance, to say that all varieties shall be correctly labelled. It is the proper thing, and if it were made compulsory at all shows, irrespective of what the produce might happen to be, the educational value of such gatherings would immediately increase by more than fifty per cent. Sweet Pea exhibitors are not, generally speaking, as great sinners of omission as many others in this respect; but even among them there is room for improvement. In classes provided by seed merchants, cards already printed are gladly supplied free of charge by the vendors of the seeds; but in other instances plain white cards ought to be in stock for use as required. The varieties selected for a special show will have their names inscribed neatly and legibly on the cards, and a few spare ones will be taken with the reserve bunches in case an alteration is deemed wise at the last moment.

Surface Cultivation.—There is no more important detail in Sweet Pea culture than this, and I would impress upon my inexperienced readers the desirability of running the hoe through the surface of the soil between the lines at every opportunity which presents itself when the ground is dry. Keep on a covering of dust 1 inch or 2 inches in depth and it will prevent waste of food, and therefore act in some degree as well as a mulching of manure. Near the plants, if one is shy of hoeing, prick over with a small fork mounted on a long shaft.

HORACE J. WRIGHT.

SEASONABLE NOTES ON CHRYSANTHEMUMS.

Early-Flowering Border Varieties.

—The value of these, both for border embellishment and the supply of cut flowers, is very great. Their flowers develop in the open air, there is no need of glass-houses for their accommodation, and so amateurs find them of much use. As the majority of the sorts are dwarf-growing and of sturdy habit, there is not much trouble entailed through staking. In rather poor or sandy soil Chrysanthemums do very well if grown in partial shade. The stems are drawn up a little more, it is true, but they retain nice green leaves and the flowers are richer in colour than is the case when the plants are grown in such soil in the scorching sunshine. So amateurs in town and suburban gardens should not hesitate to grow a few plants.

Planting Out.—If the plants are to be grown in different positions in a herbaceous border, it would be advisable to plant them in groups of three, five, seven, or even a dozen. On no account must they be overcrowded, and the groups should be composed of distinct varieties, one in each. The soil should be dug deeply and made moderately rich with rotted manure. If worked while in a fairly dry state, the soil should be made firm again before the plants are put in; then the shoots made will be strong, mature and bear flowers freely. The best effect is obtained when

feed the plants judiciously. Give them weak doses of liquid manure at every alternate watering and a pinch of some approved chemical manure to each pot. If the swelling of the stem is arrested, the sap-vessels are much contracted and they never really become normal again, so that the flowers do not attain that large size which characterises those on plants grown without check right through the season. The final potting of the plants intended for exhibition and greenhouse or conservatory embellishment must be done without delay. Late potting often results in the

wholesale damping of the flowers in the autumn. As there is not time for the roots to well fill the pots before the buds are "taken" and feeding commences, the result is damping of the flowers through the soil getting into a bad, sour state inimical to healthy root-action. Two plants may be placed in an 11½-inch pot, one plant of a strong-growing variety in a 9½-inch pot, and one plant of a weaker-growing variety in an 8½-inch one. Plants rooted in April and grown on single stems confined to bearing one flower for exhibition or grouping purposes should be finally potted in 7½-inch pots. These plants require very careful cultivation. They must not be allowed to become pot-bound, but placed in their flowering pots by the end of June at the latest. If any varieties have not made natural breaks by June 20, the plants must be stopped then, and only early-flowering sorts will bear fine blooms from such late breaks. AVON.

REHMANNIA KEWENSIS, A NEW HYBRID PLANT FOR THE GREENHOUSE.

THE GREENHOUSE

A NEW HYBRID REHMANNIA.

(R. KEWENSIS.)

HYBRIDISING, it has been said, is "a game of chance played between man and plants," and it certainly appears to

have been the element of chance that induced the hybridist to cross two very ordinary-looking plants such as *R. Henryii* and *R. chinensis*. These two species are the parents of the new hybrid. *R. Henryii* is a comparatively recent introduction from China, a dwarf-growing plant with dingy,

whitish yellow flowers. *R. chinensis* is perhaps better known as *R. glutinosa*, and is very little improvement, so far as appearances go, upon the other parent. The hybrid, however, shows a very decided advance over both parents. Its upright habit, branching from the base, is clearly portrayed in the accompanying illustration, while its large Foxglove-like flowers at once attract attention. The colour is creamy white or very pale yellow, each flower having a conspicuous crimson-maroon blotch on the upper segments. This hybrid has been raised at Kew, and for greenhouse or conservatory decoration it is likely to prove an acquisition.

only a few varieties, about six, or at the most nine, are grown in a border. The effect is much better than when single or isolated plants are put in representing many varieties.

Feeding and the Final Potting.—I know it is a fact that some cultivators are afraid to feed a Chrysanthemum plant before it has filled the pot with roots after the final potting or before it has had its bud "taken." It is not always convenient, however, to pot the plants just when they need it, and if this work be put off at all unduly, the growth of the plants will be retarded. Now, instead of allowing this to happen, the cultivator should

GARDENING FOR BEGINNERS.

CURRENT WORK AMONG THE RHODODENDRONS.

RHODODENDRONS are flowering with remarkable freedom this year, and before long their glory will have departed. Those who care for the future well-being of their plants should not omit to remove all the trusses of dead and dying flowers, and thus prevent them from seeding, for it should be borne in mind that the production of seed is a strain upon the plants. The observant man knows that Rhododendrons flower far more freely the following year if the undeveloped seed-pods are all picked off.

Colour-Schemes.—No plants lend themselves to colour-schemes so well as the Rhododendrons, and during the flowering season one should make a note of those varieties in which the colours enter into perfect harmony. Unfortunately, one too often meets with the common purplish Rhododendron *ponticum*, whose one great attribute lies in the fact that it is the only shrub never injured by hares and rabbits. It undoubtedly is a capital covert plant, growing well under trees, thriving in almost any soil and situation, and transplanting with perfect freedom; but why it should be so perpetually given a prominent place in ninety-nine gardens out of every hundred where Rhododendrons thrive it is hard to imagine, seeing that we have a host of varieties of pleasing hues to select from. The variety *Pink Pearl* is, beyond doubt, one of the most beautiful in cultivation, although it has been a little irregular in flowering; at all events, in suburban gardens. *Kate Waterer* is a rosy crimson variety with a large yellow mark; it always comes in for a fair share of admiration and never fails to flower well, while *Smithii album*, a clear white, heavily spotted, is, in the writer's opinion, the best white in cultivation. Other good varieties are *Alice* (rose pink), *Boule de Neige* (white), *Cynthia* (rosy crimson), *Doncaster* (bright red) and *Grand Arab* (a dazzling crimson). The varieties referred to are all admirably adapted for beds on lawns or borders to carriage drives.

Soil.—There exists a general opinion that Rhododendrons will only thrive in a rich peaty soil. In actual practice, however, it is found that they may be grown successfully without peat, providing a good loam may be had. The top spit of an old pasture which is fibrous and loamy, together with leaf-mould and well-decayed manure or dried cow-manure, makes an excellent compost for Rhododendrons. It should always be borne in mind, however, that a coarse, fibrous soil is greatly to be preferred to a fine one. The dislike that Rhododendrons have for lime is quite well known, and I know of isolated cases where these plants have failed even though a peaty loam had been imported. Such failures are probably due to the presence of too much lime in the water.

Although spring is the best time to carry out the work of transplanting, there are few shrubs that withstand it so well at any season, providing a good ball of soil is removed with each plant and all reasonable care is taken to protect the delicate fibrous roots from undue injury. Watering should be well attended to after planting, and the work carried out with all possible haste. Pruning is not, as a rule, necessary for Rhododendrons, although, if required to keep the plants within bounds, the knife may be used at this season. Its smooth, shiny leaves render the Rhododendron a first-rate subject for town gardens, for smooth leaves are less liable to injury from deposits of

leaf-soil, one quarter; rotted manure and coarse sand, one quarter.

The plants may be flowered in pots of various sizes, those 5 inches, 6½ inches and 7½ inches in diameter being the most useful. In some cases the seeds may be sown in the pots, the resultant seedlings thinned out in due course, and the plants retained left undisturbed in the pots to flower. This is a desirable way of treating the annuals raised late in the season to form a succession to those that flower during June, July and the early part of August. The seedlings forming the first batches of plants must be transplanted from pans or boxes, or even the open borders, while they are small, and

RHODODENDRONS ARE GOOD FLOWERING SHRUBS FOR BEGINNERS IN GARDENING, EXCEPT WHERE THE SOIL CONTAINS MUCH LIME.

soot in a smoke-laden atmosphere than are those of a soft, downy texture.

SPARTAN.

ANNUALS IN FLOWER-POTS.

MANY persons who are quite used to the cultivation of annuals in the open borders may think it is a very easy matter to grow them as well, or better, in pots. If every attention be paid to their requirements just at the right time, exceedingly fine displays of flowers may be so grown; but if neglected at all, the plants will be weedy and very unsatisfactory. There is one point that I would like to refer to at once, namely, the unsatisfactory results which follow the transplanting of annuals when they are rather forward in growth.

Ordinary soil, taken from the garden borders, will not do for our purpose. A good compost is essential, and the following may be easily procured: Turfy loam, with the fibre plentiful in it, one half;

be grown on quickly; that is, before they become at all pot-bound they should be repotted.

If the loam is of a light nature, fairly firm potting is advisable; if somewhat clayey, pot less firmly. The newly transplanted, or repotted, plants must never be allowed to droop through full exposure to the sun. At first, until they are somewhat established, shade the plants a little; a frame with a north aspect is an ideal place for them. Clear water only must be given until the flower-buds form; then judicious feeding will do much good. These pot plants are very useful for growing in yards, porches and cool conservatories.

Sweet Peas, of course, must head the list. Asters, Stocks, Zinnias, *Salpiglossis*, Marigolds, *Godetias*, *Nasturtiums*, *Mignonette*, annual *Chrysanthemums*, *Clarkias*, *Candytuft*, *Sweet Sultan*, *Phlox Drummondii*, the *Ice Plant*, *Poppies* in variety and *Calliopsis* are all beautiful. B.

GARDENING OF THE WEEK.

FOR SOUTHERN GARDENS.

Plants Under Glass.

Lapagerias.—To encourage these greenhouse climbers to make a good growth, syringe frequently and keep the roots well supplied with water. Attend to the regulating and tying of the growths, and guard against attacks from slugs. Established plants will benefit by an occasional soaking with properly-diluted farmyard manure. Keep a sharp look-out for thrips, which soon cripple the foliage.

Humea elegans.—Make a sowing now for producing good specimens to flower next summer. Sow the seed thinly in a well-drained pot or pan in a finely-sifted, sandy compost, and place in a warm greenhouse till germinated.

Tuberous-rooted Begonias.—Keep the plants well supplied with water, and occasional applications of liquid manure will be beneficial. Carefully stake the flowers with neat green sticks, and shade from bright sunshine.

Crotons.—To encourage a free growth and impart that fine colouring to the foliage, the plants need the maximum amount of sun. Now that the plants are rooting freely, more water will be necessary, and some stimulant should be afforded. Keep the growths well syringed and the surroundings thoroughly moist. Have the plants as near to the glass as possible.

Chrysanthemums.—For those who grow large blooms and do not wish to be bothered with the timing and stopping of the buds, an excellent method whereby one can ensure having them, and also a succession of flowers, is to cut the plants down almost to the ground-level the first week in June, either before or after the final potting, and allow three or four breaks to come away, taking the first bud made. This method also ensures dwarfier plants, and is to be preferred for small houses.

The Flower Garden.

Sub-tropical Bedding.—To obtain the best effects, the ground should be well worked and heavily enriched with rotten manure, choosing a sheltered portion of the garden. Stake the plants and secure them with good, strong strands of raffia to prevent injury from wind. In the event of dry weather, give the plants copious supplies of water at the roots, and damp overhead in the evening when the weather is warm.

Aquilegias.—For cutting purposes the long-spurred hybrids in their various shades of colour are indispensable. A sowing may now be made in a shady border for producing plants for next season's flowering.

The Kitchen Garden.

Asparagus.—Cutting from the permanent beds should cease from the middle to the end of the month, otherwise the crop for another season will be impaired. Keep the beds free from weed growth, and during showery weather dust with soot at intervals; this will be found effective against the ravages of the Asparagus beetle.

Broad Beans.—Another sowing may be made out of doors. Earlier sowings are now growing freely, and a stout stake or two driven into the ground at intervals with a string attached will be found good support. The earliest crop should be stopped when sufficient Beans are set; this will cause them to mature quicker, and is also the means of destroying the aphid which invariably attacks the points.

Marrows.—Give air freely to plants in frames when the weather is warm. Keep the flowers fertilised, and see that the plants do not suffer for the want of water. Keep the growths pegged down, and damp over twice a day.

Coleworts.—Make a sowing of these for following the summer Cabbages.

Cauliflowers.—Continue to plant out for succession those sown during the month of April. Thoroughly well water them in, and place a mulch of manure round those that were planted earlier. The earliest plantings should have the leaves tied up to preserve the flowers.

Endive.—The present month is a good time to make a sowing, where space permits, of a row, such

as between the Celery trenches. Thin out the plants when large enough to a foot apart.

Hardy Fruit Garden.

Cherries.—Encourage the fruits to swell by soakings of water at the root, together with the protection of a mulch. Keep the foliage clean by frequent syringings, and if aphid is very troublesome, use an insecticide properly diluted. The longest of the shoots and those required for extension should be tied in, and others pinched back.

Strawberries.—Immediately the earliest batch commences to colour, some protection must be given from the birds by stretching hexagonal-meshed netting over some supports on the bed.

Figs.—The earliest fruits will now be swelling fast, and where possible give the trees a good soaking with liquid manure-water. Tie up the longest of the growths or nail them in.

Fruits Under Glass.

Madresfield Court Grapes.—To colour these to perfection, allow plenty of foliage to mature over the berries to afford a natural shade. This variety in particular is very prone to splitting of the berries, and to avoid this give a good circulation of air whenever possible. Leave a little on at the top ventilators all night, or else air very early in the morning. Watering at the root should be discontinued when the berries commence to colour.

Late Grapes.—The thinning of such varieties as Gros Colmar and Gros Maroc must be more severely done, as was necessary with the earlier varieties. Attend to the watering of the borders and apply stimulants in variety, well washing them down. More air will now be needed and the shutting up of the house may be left till later. On warm nights the top ventilators may be reopened a little. This will be extremely beneficial to the foliage. If not already done, the borders should be mulched with rotten manure. This not only conserves the moisture, but does much to check attacks of red spider. Damp down the paths late in the evening, especially when near to the hot-water pipes. If any sign of mildew is noticed, smear the pipes with sulphur mixed to the consistency of paint and make them thoroughly warm.

E. BECKETT, V.M.H.

Aldenham House Gardens, Elstree, Herts.

FOR NORTHERN GARDENS.

The Fruit-Houses.

Melons.—Seeds for a late crop should be sown now, one seed in a 3-inch pot, from which the seedlings may be transplanted into the fruiting border.

Figs.—The early crop, as soon as it has been gathered, should be followed by means to induce the production of a second without loss of time. Generally, a dressing of manure to the border for old trees, a drenching with water and less ventilation will be all that is necessary.

Pot Trees.—Rich surface-dressings with abundant supplies of very dilute manure-water are essential to the production of fine fruit. Liberal ventilation affects the trees beneficially in many ways, and is one of the best means of keeping them immune from insects.

Strawberries.—Runners cannot be had too early, and, if not all, at least some will now be large enough to layer. It saves much labour if the layers are brought together out of so many of the interspaces and layered either in small pots, pieces of turf, or prepared soil. None of the plants is in this way overlooked when watering, which is more expeditiously performed when the plants are grouped, and weeding and other necessary work is more easily attended to.

The Fruit Garden.

Apples.—If trees trained to espaliers have not yet been disbudded, they should be seen to without further delay. As a rule, they should not be pinched, which only induces the production of more unnecessary growths, but be broken clean off, and thus give abundant space for the foliage on the spurs left to expand.

Pears.—Some trees have set enormous crops, and these are now in fit condition to thin. Small-fruited varieties, such as Winter Nelis and Bergamotte Esperen, should be much reduced in numbers, the larger fruits of these being always better flavoured.

Netting Fruit.—The early ripening of Strawberries which are very forward calls for means of protection, which for these and all other fruits should be securely placed over the fruits before they are ripe enough to tempt birds. Once these get a taste of the fruit, it is barely possible by ordinary means to keep them out.

Training.—Young trees of all kinds, but more particularly of Peaches and Plums, will need constant attention to keep the young shoots neatly nailed to the walls. Any lateral growths should be pinched while still very small. Grape Vines which do not, as a rule, fruit also need the shoots fastened loosely, or else pinched in those instances in which they are not wanted to cover walls.

The Vegetable Garden.

Coleworts.—Sow seed of London Coleworts for a full crop. They will be ready to use in mid-winter.

Late Peas.—During the incoming week make a large sowing for latest gatherings, which sometimes extend into November. The Queen and The Gladstone are two very reliable varieties, being little susceptible to mildew. Proceed as recommended for the last sowing. By no means use many seeds, and allow abundant space between the rows.

Potatoes.—When lifting the earlies, note the best plants and select the tubers from these for seed for another year. It is usual to allow the tubers to lie in the open to "green" before storing them, but they may be stored at once in an airy room where they will be isolated from disease should it attack living plants.

Vegetable Marrows.—Strong plants in 4-inch pots, planted in vacant spaces and started by means of abundance of water at the root, will grow very rapidly and produce nice Marrows for use in autumn. It is best to limit the number of shoots, three or four at the most being sufficient. Cut when young. Large, overgrown Marrows are a great drain on the energies of the plants, and for eating are of no great value.

The Flower Garden.

Tidying Up.—It not infrequently happens that routine work is neglected at this period, but it should be overtaken at once now that the fiercest of the battle with bedding plants is over.

Dwarf Plants.—The mossy Saxifrages, evergreen Candytufts, Aubrietias and dwarf Phloxes are examples of plants which it is desirable to keep neat throughout the summer months. This is best attained by means of a pair of hedge or sheep shears, the old flower-heads and straggling growths being neatly trimmed. New growth springs at once, and it is an aid to the plants to sprinkle some finely-sifted compost over them, which the first shower of rain washes down. The neat, grey-leaved Cerastium needs to be repeatedly trimmed in the same way, by which means it produces a succession of new shoots all through the summer months.

The Plant-Houses.

Pits, &c.—There are always a few structures emptied at this season, when the opportunity should be taken to clean them thoroughly, burning sulphur to destroy with its fumes any insects that may be alive.

Zonal Pelargoniums.—Those in 4-inch pots should now be at the proper stage to repot into 6-inch ones for flowering in winter. They are best stood out of doors on a cinder-bed till September. A few of last season's plants shaken out and also repotted into 6-inch pots bloom more profusely and earlier than young plants; otherwise the treatment is identical.

Arum Lilies.—There need be no further delay in planting these into a quarter of the kitchen garden to pass the summer. If increase of stock is wanted, small pieces taken off the larger plants and set singly will furnish nice material to flower in 6-inch pots. The plants otherwise, once they are deeply planted, require no further attention till the time for repotting arrives.

R. P. BROTHERSTON.

Tynningham, Prestonkirk, N.B.

DAFFODIL NOTES.

SOME GOOD, CHEAP VARIETIES FOR SHOW.—
BRECON MEMORIES.

ACCORDING to my promise in my notes of May 18, I now submit a list of a few good, cheap varieties for show. Everyone feels a little flattered when his advice has been followed, and pardonably so, I hope, when it has led to good results. So, just as a dealer prefaces his catalogue with an account of the medals and prizes he has won, in order to show the goodness of his wares, may I be allowed to refer to the success of my friend, Mr. A. C. Carne Ross of Brecon, at the Brecon show this year. Brecon to me is an ideal local Daffodil show. To begin with, they have got the right people at the head of affairs—Lord Glanusk, who "works like a horse," and Miss A. de Winton, who is energy personified. Then such competitors! all "as keen as mustard"!—Captain Kitchin and Mr. Carne Ross, among others. I was afraid the exigencies of soldiering would lose us the former, but the powerful magnet of the garden has drawn him from the Service, and a hard-to-beat man has been saved. Mr. Ross is a typical plodder, who is year by year, with careful discrimination, building up a collection of good, reliable sorts which are just the thing for shows. He did very well indeed this year, and he has already asked my advice with regard to additions for 1913. I hope what I have suggested will be found to have been helpful; ditto, when what follows is read. Cornelia, Monarch, Mrs. H. J. Veitch, Mervyn and King Alfred are all excellent yellow trumpets that, when shown in good form, take some beating. Among bicolors there are Duke of Bedford, Coronet, Cygnet, Dorothy Kingsmill and Waxwing. In the white trumpets Mme. de Graaff is indispensable; Treasure Trove and Princess are certainly the pick of the bunch of the rather expensive sort. The former may be had for half-a-sovereign, and the latter for half-a-crown more. Both are good, refined flowers with flat, symmetrical perianths, broad and overlapping segments and shapely trumpets.

Coming to Division II. (*incomparabilis*), in section (a), with yellow perianths, Blackwell cannot be too highly recommended, and the same may be said of Homespun. This last-named variety is a soft yellow self, to which the words "of perfect form" may truthfully be applied to all well-grown specimens. Solfatare is certainly one to go for. Apart from its great merit as an extraordinary lasting garden plant, the pale colouring of its *Nelsonii*-like cup and its large imbricated, but yet rather loosely-built, perianth give it a very distinct character. The splendid old red-cupped *Gloria Mundi*, it must be remembered, is still one of the best. Among the white perianths, I put Whitewell as an outstanding flower of the highest merit, "alho' I says it as shouldn't," it being my own introduction. This last season it must have been seen at almost every Daffodil show in the kingdom, and it invariably held its own, although the dry and hot summer of 1911 did not suit it very well. Brigadier, a pointed Lady Margaret Boscawen, is a variety of great merit, and not so well known as it should be. "A good 'two-bob' flower" is my comment. The bicolor Steadfast is one of the late varieties that the present curious season has brought into prominence. It is a true florists' flower, and very satisfying to the "con-noise-er."

The new Barri division (No. 3) is a large one, and selection is difficult. Perhaps among the yellow perianths Coreen, Castile, Cœur de Lion and Occident, and among the white perianths Circlet, Incognita (especially if you could buy a bit of the Lissadell climate with it), Ethelbert and Sunrise, are the ones I would be going on with until the longingly wished-for time of Challenger, Queen of Hearts and Sheba, being mine, should come.

In the 1910 arrangement of classes all the Leedsii are put together. I regret it, as it is a division of many types, and I fear, looking at the present trend of judging practice, that some of the most beautiful forms will drop out. We want Countess of Southesk type, and we want Empire type, and we want Venus type. I hardly know what to advise, but no one can be wrong in acquiring Evangeline (a pale bicolor Homespun), Pilgrim and Countess of Southesk (two Frank Miles sorts of Leedsii), Diana (it was good with me this year) and Easter, with a few bulbs of the indispensable White Queen.

Doubles and bunch-flowered kinds, as also triandrus and Jonquil hybrids, I must let severely alone. This leaves me with only the Poets, and what to say about them I do not quite know. They all seem to have such a liking for poor Edward Terry that they will go in for copying his neck. The worst of it is, they always seem to take a special delight in showing off their mimicry just when you do not want them to. Well! readers, all we can do is to humour them, and take them at their own time, and tell them if they will only do as we want them for a short time when we are showing them to our visitors, they can play at Edward Terry necks ever afterwards. Cassandra, Virgil, Homer, Horace, Laureate, Matthew Arnold and George Herbert are among the best behaved, but the choice is so great and the differences so small that I hesitate to advise.

Of one thing I am certain: early planting is the golden key that unlocks the prizes in the following spring.

JOSEPH JACOB.

LEGAL POINT.

Notice to Quit (*Joycey*).—If a tenant holding under a three years' agreement remains in possession after the expiration of the term, paying rent quarterly, he becomes, apart from express agreement to the contrary, a tenant from year to year. Such tenancy can be terminated by the customary half-year's notice given for the end of the current year of the tenancy, *i.e.*, it must be given for a date corresponding with that on which the tenancy commenced. If the tenancy did not commence on one of the customary feast days, the notice must not be less than 182 days. If the tenancy commenced on Lady Day, the notice must be given on or before Michaelmas Day. Of course, this is all liable to be modified by the express stipulation of the parties; by express contract they may do what they please. In case of an agricultural holding, apart from contract to the contrary, a year's notice must be given. A tenant who only intends to stay for a year should decline to sign an agreement whereby the premises are demised "for one year and so on from year to year," as such tenancy would endure for two years. The landlord is right in his contention put by the querist, and a fresh notice, given on or before Michaelmas Day for March 25, is necessary, unless the landlord can be induced to accept a surrender at an earlier date.

BARRISTER.

ANSWERS TO CORRESPONDENTS.

RULES FOR CORRESPONDENTS.

QUESTIONS AND ANSWERS.—The Editor intends to make THE GARDEN helpful to all readers who desire assistance, no matter what the branch of gardening may be, and with that object will make a special feature of the "Answers to Correspondents" columns. All communications should be clearly and concisely written on one side of the paper only, and addressed to the EDITOR OF THE GARDEN, 20, Tavistock Street, Covent Garden, London, W.C. The name and address of the sender are required in addition to any designation he may desire to be used in the paper. When more than one query is sent, each should be on a separate piece of paper. Plants for naming should be clearly numbered and securely packed in damp grass or moss, not cotton-wool, and flowering shoots, where possible, should be sent. It is useless to send small scraps that are not characteristic of the plant. Letters on business should be sent to the PUBLISHER.

FLOWER GARDEN.

NARCISSUS GROWING WILD (*B. A. I.*).—The flowers were rather faded; but we have very little doubt but that it is *N. hiflorus*, which is found wild in certain parts of Britain.

CENTAUREA ATTACKED BY FUNGUS (*J. P.*).—The *Centaurea* is attacked by the rust fungus (*Puccinia suaveolens*). The same fungus attacks *Thistles*, and usually prevents them flowering. We fear that, when once attacked, nothing can be done to cure the plants. We recommend you to root out the worst attacked, and to spray the rest with a rose-red solution of potassium permanganate.

WHITE-FLOWERED BEDDING PLANT (*Wulfruna*).—If needs be you might reduce the grossness of growth of the *Marguerite* by plunging the plants in pots instead of planting them out. In this case, however, they would require more attention in the watering. Other suitable subjects would include white *Petunia*, white tuberous-rooted *Begonias* and white *Phlox Drummondii*, all of which are free and profuse flowering.

LILIES FAILING (*L. J.*).—It is difficult to account for such wholesale failure as that you describe unless you put it down to the heat and drought of last year, and these, exceptional as they are, can hardly be held absolutely responsible for the wholesale failure of long-established clumps, though they might have much reduced their strength. You do not say whether you have examined the positions where the complete failure has occurred to discover the present condition of the bulbs. This might have shed some useful light in the circumstances. Occasionally, when the bulbs have long remained in one place, they sicken and become a prey to root fungus; though of personal knowledge we know of fine clumps in your county that have done well for many years without much care. The sharp spell of frost in the early spring of this year could not have injured the plants unless growth was forward, and that evidence would have been before you. In the circumstances we can only advise you to examine the positions where the bulbs have been and glean all possible information. Had the bulbs given a prodigious flowering last year, that, with the heat, might have been held responsible, as collapse frequently follows. When you have made an examination, write us again.

TREATMENT OF EREMURI (*J. S. E.*).—If the bed was only made and planted in January last, the plants will require well looking after to prevent disappointment ensuing next year. The planting was done much too late, and early October—the season when, under normal conditions, root action is set up anew—would have been far better. Because of this late planting the current growth may suffer, though that would be governed by local conditions and the method of planting. Hence for the moment encourage the best possible development of the plants, affording them water or liquid manure occasionally if dry weather is experienced, in addition to a mulching of manure. The *Eremuri* do not root deeply or numerously, but send out tlong-like roots which radiate horizontally from a common centre, and in two or three years such roots may be found 3 feet or even 4 feet from the crown of the plant, and often not more than 6 inches or 8 inches below ground; hence the soil should not be much or deeply disturbed within these limits. A light pricking over of the surface and a mulching of half soil, half manure, would be helpful to more established plants than yours. In winter, mulch the plants well with litter or the young leaves of Bracken. Nearly all the *Eremuri* suffer from the keen winds and frosts of spring; hence a position sheltered from the north and east is desirable, the shelter of a shrub-belt being the best of all. Do not allow the plants to ripen seeds this year; it will only tend to weaken them.

TREES AND SHRUBS.

"YELLOW" WISTARIA (*J. C. K.*).—The mention of yellow-flowered *Wistaria* to which you allude was probably made by a reporter who did not possess a very good horticultural knowledge. We have not heard of a kind bearing yellow flowers, and it is probable that the *Laburnum* flowers were mistaken for *Wistaria*.

VALUE OF TIMBER (Gardener).—It is not possible to give any hard-and-fast price for timber, as the price of the same kind and quality of wood differs considerably in different parts of the country, and even within a few miles. Several pence per cubic foot more may be obtained for wood within an easy distance of a station or waterway than for that which is in a position several miles away from a station. Good average Oak may sell for anything between 1s. 6d. and 2s. 3d. a cubic foot. Scots Fir, if of good quality, rarely sells for more than 6d. a cubic foot in the South of England. Spruce sells for the same price; Larch from 1s. to 1s. 2d. a cubic foot; Poplar, 6d. to 10d.; and Beech, 9d. to 1s. 6d. Rough trees have to be sold for less money.

FRUIT GARDEN.

MAIDEN APPLE TREES (E. S. K.).—We should certainly take off the flowers. It would cripple the young trees' growth for many years to allow them to carry fruit as maidens.

VINE LEAVES WITHERED (A. S.).—The leaf sent is perfectly healthy; but being young as yet, it is, of course, tender. The cause of the edges turning slightly up, we think, is the recent great heat and too close an atmosphere in the house. Ventilate more freely while the weather is so hot, and thus keep down the temperature; and, of course, you will see that the Vines do not suffer from the want of water at the roots. Before the next watering is done, give the border a fair sprinkling of lime, forking it in about two inches deep, and then water. For green fly, vaporise with XL All, half the strength recommended for red spider and thrip. This will bring the fly down and will not hurt the Vines.

MISCELLANEOUS.

NAMES OF PLANTS.—E. M. Parkstone.—Muscarri comosum plumosum.—E. H. W.—Valeriana Phu (the Cretan Spikenard).—E. B. Wigam.—1, Pyrus Aria; 2, Acer Psedno-platanus.—E. S. Bucks.—Pyruslobata.—F. U., Westerham.—Veronica gentianoides.—F. Luvani.—The Rose had dropped all its petals and was past recognition.—E. W., Devon.—1, Spirea japonica variegata; 2, S. japonica; 3, S. tomentos; 4, S. aranta; 5, S. species; 6, S. Van Houttei.—W. J. B.—1, Muscari comosum plumosum; 2, Olearia gunniana; 3, Scilla peruviana.—E. F. C., Hants.—Rosa hispida.—E. G., near Leicesters.—Phlomis tritocosa.—C. E.—Fabiana imbricata.—H. T.—1, Ceanothus dentatus; 2, Iris sibirica orientalis; 3, Thalictrum aquilegifolium; 4, Diervilla rosea; 5, Iaula glandulosa; 6, Achillea Kellereri; 7, A. tomentosa; 8, Lychnis Viscaria flore pleno; 9, Geum intermedium; 10, G. chiloense variety; 11, Berberis species; 12, Silene species, specimen too scrappy to identify. The others are garden seedling forms of Heuchera.

SOCIETIES.

ROYAL HORTICULTURAL SOCIETY.

UNQUESTIONABLY the chief feature of the fortnightly exhibition held on June 4 was the magnificent display of Sweet Peas staged by Messrs. Dobbie and Co., while a gorgeous bank of Orchids from Lieutenant-Colonel Sir George Holford's garden served as a further proof, if such were needed, of the admirable way in which these gems of the floral world are grown at Westnabirt. Hardy plants, Roses and greenhouse flowers were alike well represented at the hall on this occasion; the tall spikes of Delphiniums and Erenuri, together with showy Poppies in their Oriental magnificence, were the admiration of all.

FLORAL COMMITTEE.

Present: Mr. H. B. May (chairman), and Messrs. C. T. Drury, W. B. Cranfield, W. J. Bean, J. W. Barr, G. Renthe, C. Blicke, W. Howe, C. R. Fielder, J. Jennings, R. C. Reginald Neville, G. Gordon, A. Turner, C. Dixon, W. Cuthbertson, J. T. Bennett-Poe, Charles E. Shea, C. E. Pearson, W. T. Ware, W. P. Thomson, E. H. Jenkins, W. J. James, G. Paul, J. Hudson, F. Page-Roberts and R. Hooper Pearson.

Messrs. G. Bunyard and Co., Maidstone, arranged a particularly good table of herbaceous subjects, which included Pyrethrums, Peonies, Spanish Frises, Heucherias, Poppies and other good and showy plants. The Poppies and Peonies made a particularly fine bank of colour, and lightened by the other flowers named made up an exceedingly attractive whole.

Mrs. E. Lloyd Edwards, Bryn Oerog, near Llangollen, showed baskets of hybrid Heucherias in charming variety, such as Queen Mary (scarlet), Princess Mary (pink), Liberty (scarlet, small-flowered) and Edge Hybrid Improved (a pink-flowered form) being among the best. Her Queen of Roses is also a charming flower.

Mr. G. Renthe, Keston, Kent, displayed a small group of hardy things, in which were seen Orchises, Coronilla montana, Calochortus pulcherrus, Campanula Stevenii, Silene Hookeri, Lewisia Howelii and other good and useful plants. Viola hosniaca in this group was a very charming plant.

Mr. E. J. Hicks, Hurst, Berks, had a display of rambler and other Roses, the more attractive being Trier, the yellow Harrison, Soleil d'Or, and Sarah Bernhardt, the latter of rich crimson shade.

Messrs. James Veitch and Sons, Limited, Chelsea, showed a delightful series of Nemesias, of which Blue Gem, White Gem and Orange Prince were among the more noticeable.

Messrs. Kelway and Son, Langport, had a display of single and double flowered Peonies with occasional groups of Delphiniums. Among Peonies, Heart's Desire (pink, gold anthers), Meteor (crimson), Pride (maroon) and Tinted Venus were the best in a rather extensive exhibit of these things. Delphinium grandiflorum plenum was also well shown; it is a double-flowered variety, and a by no means commonplace plant.

Messrs. J. Peed and Sons, West Norwood, S.E., displayed a splendid lot of Gloxinias, mostly of named varieties, and generally of a superb, well-flowered strain. The fancy or spotted-flowered varieties were very charming. Ruth (violet), Mrs. John Peed (violet and white) and Queen Alexandra (of pinkish hue) being notable. Streptocarpus were also well exhibited by this firm.

Mr. Leslie Greening, Richmond, had a small corner display of rockwork associated with alpine and aquatic plants.

Messrs. Dobbie and Co., Edinburgh, staged a delightful lot of Sweet Peas, the flowers superbly grown and not less superbly displayed. It was indeed a magnificent exhibit, and one of the best; it is hardly likely to be surpassed in the present season. Elrida Pearson (pink), Melba (salmon), Dobbie's Scarlet, Afterglow, Mauve Queen, Mrs. Hugh Dickson (pink and cream), Thomas Steven-son (orange scarlet) and Dobbie's True Lavender were a few of what might be regarded as the indispensables of a capital lot.

Messrs. Paul and Son, Cheshunt, had a rather extensive display of Peonies and Heucherias, Whiteley, of the former, pure white with golden anthers, being most conspicuous.

Messrs. Phillips and Taylor, Bracknell, Berks, showed Poppies, Pyrethrums and Water Lilies in variety.

Messrs. E. W. King and Co., Coggeshall, Essex, displayed a delightfully artistic exhibit of Sweet Peas, arches, vases and groups tending to show these flowers to the best advantage. This was a really beautiful lot most pleasingly arranged.

Messrs. F. Cant and Co., Colechester, had some lovely Roses, Una, Irish Elegance, Mme. Melanie Souper and Pami's Carmine Pillar catching the eye at once.

The Misses Hopkins, Shepperton-on-Thames, had an interesting exhibit of hardy things, Pinks, Onosma taurica, Dianthus neglectus and Aubrietia Lloyd Edwards being noted in a nice lot of things.

Messrs. W. Cutbush and Sons, Highgate, N., exhibited a very taking lot of Hydrangeas in the newer varieties, Mme. E. Moullière (white) and General de Vibraye (pink) being among the more conspicuous.

Messrs. Reamsbottom and Co., Geashill, Ireland, displayed in very charming variety the St. Bridgid Anemones in many shades of colour.

Messrs. Fells and Son, Hitchin, had a display of Pyrethrums and Frises.

Messrs. T. S. Ware, Limited, Feltham, brought Frises, Poppies, Erenuri, Gaillardias, Campanulas, Iris ochroleuca, Delphiniums, Antirrhinums and Heucherias, together with a small assortment of alpines, the whole filling a rather lengthy table. Lewisia Cotyledon and Mazus Pumilio were notable things.

Messrs. Stuart Low and Co., Enfield, staged a bright and effective group of Carnations, both as pot plants and in the cut state. Lady Alington, Baroness de Brien and Princess Juliana were all well shown, as also were some well-flowered Hydrangeas.

Mr. C. Blicke, Hayes, Kent, staged some admirable border Carnations, of which King George (pure white), Attraction (pure white—award of merit), Arzonant (scarlet), Queen Mary (salmon, clove-scented), Dauntless and Thomas & Becket, both yellow faneties of splendid size, were among the best in a superb lot of flowers. Donald MacDonald, also a yellow-ground laney, was in fine form. It is very rich in colour.

Messrs. J. Veitch and Sons, Chelsea, had a most interesting table of Cannas, Calceolarias, standard Fuchsias and Heliotropes. Cilanthus Dampieri and Lavatera assurgentifolia (violet and white flowers and woolly leaves) were also noted. Elaeocarpus reticulatus, with white, deeply-fripped flowers, was most charming and very profusely flowered.

Mr. G. Ferguson, the Hollies, Weybridge, showed a table of Delphiniums, chiefly of blue and white varieties, the latter more remarkable for their numbers than their intrinsic beauty or merit.

Messrs. S. Bide and Sons, Limited, Farnham, Surrey, brought a delightful lot of Sweet Peas in some thirty or more distinct varieties.

Cannas, Frises, Fuchsias and Pelargoniums were well shown by Messrs. Cannell and Sons, Swanley, Kent. Of the Pelargoniums there were no fewer than three dozen vases in the best varieties, and displayed with this firm's well-known skill.

Messrs. Paul and Son, Cheshunt, had a table of Moss and garden Roses, of which Iris Glory, Austrian Yellow Briar, Austrian Copper, the Double Yellow Scotch and sinica were notable examples. Una, too, was very charmingly displayed.

Mr. L. R. Russell, Richmond, had a table of rockwork and alpine plants, arranging colonies of Sedums, Edelweiss, Achillea, Campanula and other suitable subjects.

Baker's, Wolverhampton, had a rich display of Lupines, Poppies in variety and Viola cornuta purpurea, the whole making a showy lot.

Mr. James Douglas, Great Bookham, staged some admirable Carnations of the border class, of which Elizabeth Schiffer, Mrs. G. A. Reynolds (orange buff), Agnes Sorrel (maroon) and Margaret Lennox (yellow ground with scarlet border) were very fine.

Mr. H. Burnett, Guernsey, showed a magnificent lot of Perpetual-dowering Carnations in such varieties as Scarlet Glow, R. F. Felton, White Enchantress, Marjoun, Mikado, Mrs. C. F. Raphael, White Wonder and Mandarin.

Messrs. Piper, Barnes, Surrey, had a table of good hardy things, the more telling being Primula hulleivana, Dianthus deltoides Brilliant, Polemonium flavum, Campanula van Houttei, C. pulia and the new Wallenbergia gentianoides, a pretty and graceful plant, 18 inches high, with clear pale blue bells.

Messrs. H. B. May and Sons, Edmonton, had some particularly good groups of Heliotropes, Exora Williamsii, Swainsona galegifolia, S. g. alba and Verbenas in variety.

Messrs. Carter Page and Co., London Wall, showed Dahlias and Violas in variety.

Messrs. R. H. Bath, Limited, Wisbech, brought fine collections of Peonies and Pyrethrums.

An exquisite collection of views of Bulgaria, exhibited by A. Delmard, Esq., for H.M. King Ferdinand, came in for general admiration. Those views particularly from the neighbourhood of Sofia and Euxinograd created a good deal of interest among the visitors. The numerous scenes depicting the wild, rugged mountains of the Balkans, together with those of the King's gardens and quaint monasteries on the mountain slopes give to the stay-at-home Britisher an idea of the conditions that prevail in this Balkan kingdom.

Mr. James Box, Lindfield, Sussex, was represented by a brilliant display of Frises, Delphiniums and Oriental Poppies.

A nice lot of Roses, including such fine things as Rosa sinica Anemone, Austrian Copper, William Allen Richardson, Austrian Yellow and Mme. A. Carrière, was shown by Mr. George Prince of Oxford.

Mr. Amos Perry, Hardy Plant Farm, Enfield, had a brilliant display of Oriental Poppies in various hues, also Dietamnus caucasicus and a number of good hardy Lilies.

A first-rate collection of greenhouse Calceolarias, well grown and of excellent colour, was shown by V. Phillips, Esq., Crofton Court, Orpington (gardener, Mr. T. Hobbs).

The new Zonal Pelargonium Champion, which received an award of merit, was shown in quantity by Mr. P. Ladds, Swanley Junction, Kent. It will be described under "New Plants" in our next issue.

Six new and rare plants, viz., Dracocephalum bulbatum, Wildenia candida, Oxalis adonophylla, Primula yunnanensis, P. membranifolia and P. pulchella, were shown by Messrs. Bees, Limited, Liverpool.

Messrs. Whitelegg and Page, Chislehurst, Kent, showed Geum Mrs. Bradshaw, Delphiniums in variety and Calceolaria Chibranii in great profusion among other tree-flowering plants.

ORCHID COMMITTEE.

Present: Sir Harry J. Veitch (chairman), and Messrs. Gurney Wilson, R. G. Thwaites, F. Sander, F. J. Hanbury, A. McBean, W. Cobb, J. Cypher, W. H. Hatcher, J. E. Shill, H. G. Alexander, A. Dye, W. H. White, J. Wilson Potter, W. Bolton, de B. Crawshaw and C. J. Lucas.

Lieutenant-Colonel Sir George Holford, K.C.V.O., sent a splendid group of Orchids, among which were some well-flowered specimens of Cattleya Warscewiczii of good form and colour; Laelia-Cattleya canhamiana and Laelia Marti-netti The Prince, which was well coloured and had four spikes carrying sixteen blooms. Miltonias were also in most excellent condition, M. vexillaria Empress Augusta Victoria being perfect. Brasso-Cattleya digbyan-mossie was also well finished and of good substance. Oncidium divaricatum, with two large branching spikes nearly five feet in length, made a good centre, and the white form of Cattleya Dusseldorferi Undine was most effective. Odontoglossums and Dendrobiums were also included. The whole group was tastefully arranged by Mr. H. G. Alexander, and secured the gold medal.

Messrs. Hassall and Co., Southgate, showed a choice collection, including the white form of Cattleya Mendelii, Anguloa Clowesii and Dendrobium acuminatum. Silver Banksian medal.

Messrs. J. and A. McBean, Cooksbridge, Sussex, staged a choice group, among which we noticed Odontioda Cooksonii, O. Charlesworthii, with its rich, deep-coloured flowers, and several Miltonias and Odontoglossums. Silver Banksian medal.

The Liverpool Orchid and Nursery Company staged Laelia-Cattleya Cowanii. This was a most striking flower, with rich orange and earmine shaded sepals and a deeper labellum. Other notable hybrids were L.-C. Eudora and L.-C. dominiana. Bronze Banksian medal.

Mr. A. W. Jensen, Lindfield, Hayward's Heath, staged some good flowered Cattleyas, Odontoglossums and Cypripediums.

H. S. Goodson, Esq., 85, West Hill, Putney, had a most interesting group of plants, consisting largely of Odontoglossums, Cattleyas, Laelia-Cattleyas and Laelias. A silver- gilt Flora medal was awarded.

Mr. H. A. Tracy, Amysand Park Road, Twickenham, staged Dendrobiums, Oncidium, Odontoglossums and Masdevallias. A white form of Cattleya Mossiae was noticed, also a distinct form of C. Mendelii of good colour. Dendrobium Falconeri was also well flowered.

Messrs. Stuart Low and Co., Bush Hill Park, staged an interesting group, prominent among which were Oncidium Kramerii, Dendrobium densiflorum, Laelia-Cattleya Eudora, Niebe and canhamiana. Dendrobium thysiflorum was also well flowered, and the pretty Bulbophyllum Lobbii attracted attention. Silver Banksian medal.

Messrs. Sander and Sons, St. Albans, were in their usual form and presented a most attractive exhibit. Odontoglossum amabile x O. eximium was in good form. Miltonias were well represented, and Odontioda Bradshawia variety vivians is a most beautiful form. Silver Flora medal.

Messrs. Charlesworth and Co., Hayward's Heath, were strong in Phalaenopsis rimestadiana with large spikes of well-formed flowers. Odontoglossum Illustrissimum is a most striking form and colour. Cattleyas and Laelia-Cattleyas were also good. Silver Flora medal.

EDITORIAL NOTICES.

Every department of horticulture is represented in **THE GARDEN**, and the Editor invites readers to send in questions relating to matters upon which they wish expert advice.

The Editor welcomes photographs, articles and notes, but he will not be responsible for their safe return. All reasonable care, however, will be taken, and where stamps are enclosed, he will endeavour to return non-accepted contributions.

As regards photographs, if payment be desired, the Editor asks that the price required for reproduction be plainly stated. It must be distinctly understood that only the actual photographer or owner of the copyright will be treated with.

*The Editor will not be responsible for the return of artistic or literary contributions which he may not be able to use, and the receipt of a proof must not be taken as evidence that an article is accepted. Publication in **THE GARDEN** will alone be recognised as acceptance.*

Offices: 20, Tavistock Street, Covent Garden, W.C.

NOTES OF THE WEEK.

Lælio-Cattleya Fascinator.—Among the numerous Orchids that flower during the month of May, the plant just quoted occupies a high position. It is of easy culture, and deserves a place in every collection where Cattleyas are grown. The sepals and petals are almost white, while the large open lip is streaked and marked with rosy purple. The parents are the two fine species *Cattleya Schröderæ* and *Lælia purpurata*.

Primula pulverulenta Mrs. R. V. Berkeley.—The type of this charming variety is one of the most popular hardy Primulas in commerce, and any variation such as we get in the old *P. japonica* will be welcomed by all hardy plantsmen. The subject of the present note appeared as a sport among a batch of *P. pulverulenta*, and it was among the best of the novelties at the recent International Show. As in the type, the flowers are borne in whorls, but they are white with a small yellowish circle at the top of the corolla tube. There will, no doubt, be a great demand for this new plant, for it is a decided acquisition to the genus.

Rheum Alexandræ.—This very distinct Rhubarb, one of the novelties of 1909-10, is proving a good and striking plant, curious, yet pretty in its way, and useful for conspicuous situations where some character is required. It derives much of its value from the yellow bracts of the flowering stems, these being quite leaf-like in character and the stems being three feet or so high; these bracts show up well in the garden. The leaves are of a dark, shining green, and the whole plant is one of decidedly novel appearance. It is perfectly hardy, and has been found to be so in several gardens into which it has found its way.

A Showy Chinese Shrub.—The showy character of *Sophora viciifolia* has resulted in its rising to a conspicuous position among flowering shrubs in a short space of time, for it is not more than a dozen years since it was received into general cultivation. It differs widely from the well-known *S. japonica*, for, whereas the latter grows into a large timber tree, the newer species is of shrubby habit. Growing at least 6 feet high in the open ground and 12 feet against a wall, it forms a shapely specimen, with rather stiff, spiny branches clothed with small, bright green, pinnate leaves. The Pea-shaped flowers are borne in short inflorescences in June; the prevailing colour is white, but there is a distinct violet tinge, due mainly to the prevalence of that colour in the calyx. It may be propagated by means of seeds, which ripen freely, or by cuttings

inserted in sandy soil in a cold frame in July or August. Any ordinary garden soil suits it, that of a loamy character being the best. As large plants transplant badly, it should be placed in a permanent position while quite small.

An Effective Garden Poppy.—One of the prettiest of all annual or biennial Poppies is *Papaver umbrosum*, which is most effective among grass, and a fine display was made in this way at Kew lately. Nowhere does it look so fine as with this groundwork of greenery, but it is a lovely plant for the garden, and usually reproduces itself from self-sown seeds after it has once been introduced. The best plants are from autumn-sown seeds, but, hardy as it usually is, there are springs in which all the young plants may be killed, so that it is as well to save a few seeds every year for emergencies. This is a bitter lesson learned by a cultivator, who had every young plant of *Papaver umbrosum*, of which there were hundreds, killed one untoward season. The autumn and early winter had been unusually open, and the Poppies grew until after the New Year, when severe frosts, alternating with rains, came, and the *Papaver* succumbed. It is a charming Poppy, with deep but bright crimson flowers, each with a black spot at the base of every division of the flower, and the plant grows from 1 foot to 1½ feet in height. Seeds can be sown in the open in August for next year's bloom.

The Neill Prize for Horticulture.—The council of the Royal Caledonian Horticultural Society has this year awarded the Neill Prize to Mr. John W. M'Hattie, the Edinburgh City gardener. The prize, awarded for eminent services in horticulture, is the interest of a sum of money bequeathed by the late Dr. Patrick Neill for the purpose, and it is awarded every two years. The distinguished services rendered by Mr. M'Hattie to Scottish horticulture are well known and generally recognised. Since he entered upon his present appointment at Edinburgh about eleven years ago, he has effected great improvements in the city parks and gardens. While filling private appointments he was a highly-successful exhibitor, and secured many of the highest awards from the Royal Horticultural Society, the Scottish Horticultural Association and other horticultural societies, these awards including Veitch Memorial medals, a Banksian medal and the City of Edinburgh Cup. A native of the North of Scotland, Mr. M'Hattie held with great success several important private appointments before he entered upon that at Edinburgh, such as Newbattle Abbey and Strathfieldsaye. Mr. M'Hattie takes an ardent interest in the affairs of the principal Scottish horticultural societies and renders them yeoman service, so that the award will be generally acceptable to the members and others.

CORRESPONDENCE.

(The Editor is not responsible for the opinions expressed by correspondents.)

A Good Trumpet Daffodil.—Having read the note, "Exhibition *versus* Private Garden Flowers," by "An Amateur," in THE GARDEN for June 1, in which he would like to know the name of a good late yellow trumpet Daffodil, we venture to say that The Doctor, a Daffodil we saw in the Rev. Joseph Jacob's garden at Whitewell, is one of the very best of all the yellow trumpets, and it is a late flowerer, expensive now, but a good variety and very effective.—ALDERSEY AND MARSDEN JONES, *Tilston, Malpas, Cheshire.*

A Useful Early Pea.—Anyone desirous of becoming acquainted with an early, productive and profitable culinary Pea would do well to give Veitch's Acme a trial. Growing about three and a-half feet high, with a strong haulm, it is simply smothered with pods from bottom to top, filled with nine to eleven good-sized Peas. Sown this year on February 14 in the open ground, splendid pods were gathered on June 1. Grown side by side with Chelsea Gem, sown the same date and under exactly the same conditions, Acme proved eight or nine days earlier.—J. B., *Margate.*

Genista mantica.—An Italian Broom which is but seldom cultivated even among good collections of shrubs is that called *Genista mantica*. It is not considered very hardy, but I think this is a mistake, at least so far as districts with a moderate climate are concerned. Two plants of *G. mantica* have been in my garden for at least six years, and they are growing well, although one of them, which is in a very exposed position, suffers at times from sharp and severe winds in winter and never makes the headway of the other. The latter is partly sheltered by other shrubs from the north winds, and flowers well annually, giving a good supply of its pretty, small yellow flowers.—S. A.

Zonal Pelargonium Hall Caine.—I am quite in accord with your correspondent (page 290, June 8), regarding the merits of this beautiful variety, although we certainly do not see eye to eye in the matter of colour. Your correspondent speaks of it as salmon, but to me it appears to be of a beautiful soft shade of red. According to the catalogues it is cherry red. It forms a grand pot plant, but is, I think, less grown now than it was at one time, probably owing to the fact that some of the newer kinds bear their flowers in larger trusses. A peculiar feature of this variety is that it frequently pushes out a secondary truss, which continues the period of flowers. Several varieties do this occasionally, but in the case of Hall Caine it often happens. There is another variety, Phyllis, which is in many ways almost a counterpart of the preceding, but the flowers are of a pleasing shade of soft salmon cerise.—H. P.

The Rose Acacia.—When this plant is in blossom during June or early July, the remark is often expressed that "it ought to be more largely grown," for there are few shrubs blossoming at that period which are more effective; yet it never appears to become common, for there are not many public gardens where it is well represented. The Rose Acacia (*Robinia hispida*) is a native of the United States of America, where it forms a dense, thicket-like growth from suckers. The rose-coloured flowers, which are as large as those of a culinary Pea, are borne in small racemes and are very effective. Better than the type, however, is the variety *inermis*, which lacks the stiff hairs

on the branches from which the former takes its name. Unfortunately, neither plant produces seeds, and propagation has to be effected by means of root cuttings or by grafting upon the common Robinia. Both plants thrive in ordinary garden soil of a loamy nature.—W. D.

The Cherokee Rose (*Rosa sinica laevigata*).—This very handsome Rose is flowering grandly on a south wall this season, and it is the first time it has flowered. This Rose is most beautiful. It has single white flowers with golden stamens; the flowers are 5 inches to 6 inches across, and present a magnificent appearance set in the beautiful shining green foliage, which is evergreen. I believe this Rose is found in the South of France and Italy, but its home is in the Himalayas, where I have heard of its being seen in great beauty, but not so large as when cultivated. It is not generally hardy, therefore its place is on a warm wall. It does not harbour pests like our Roses.—W. A. C.

A New Sweet Pea.—I do not know how far hitherto that well-known Daffodil-raiser, Mr. Herbert Chapman of Rye, may have entered the lists of Sweet Pea raisers, but those, in any case, are legion. Hence it is so very much the more meritorious when, out of the legion, but one here and there is fortunate enough to raise something that is exceptionally good. I think in his new waved pure white, *Iolanthe*, he has a really fine variety. I am in receipt from him of a bunch of blooms, and the flowers are exceptionally fine, being set in fours and fives on the long, stout stems. There is a solid whiteness about the flowers that is so attractive. If Mr. Chapman has sent his variety to the Sweet Pea Society's trials, it will there have to pass through a severe ordeal, as also it will when presented at the society's show next month. Necessarily, I see that alone. I have neither Etta Dyke nor Nora Unwin here for comparison, but *Iolanthe* is a superb white, all the same.—A. D., *Kingston.*

Anemonopsis macrophylla.—It will probably be interesting and possibly useful to some to say that *Anemonopsis macrophylla* has flourished well with me here for the past seven years, after it had been equally successful in a former garden of mine a few miles away. It has been all that time in the border, in common loam, rather on the dry side, possibly, for some things, but evidently suiting the *Anemonopsis*. My plant came originally to me as a seedling sent me by the late Rev. C. Wolley-Dod from his garden at Edge Hall, and it has never looked back since then, although increasing in size but slowly. It flowers annually, giving its charming pale rose and white flowers in a fairly free manner. They remind one of small-sized blooms of some of the pink or rose varieties of *Anemone japonica*, so that one can hardly quarrel with the name of *Anemonopsis*. I have been much interested in the remarks of Mr. Reginald Farrer in his "Alpines and Bog Plants," in which he discusses this plant in a manner not calculated to inspire confidence in its ways, though his later experiences were more favourable than his first ones. Mr. Farrer tells us that it has a bad reputation in gardens, and with this I quite agree. Like me, he first saw it at Edge, and resolved that he must possess it in health. He had, it appears, many failures, but finally put it out, when a fresh lot had been received, into a "rich border of peaty loam fattened with manure." Here success finally rewarded him; and he then speaks in glowing terms of the way the *Anemonopsis* took possession of its place. But there is a suggestive addendum,

as follows: "Latest news: this tale is too rosy"! My border was composed of fresh soil from a field with the turf dug in, and no manure was given. In my former garden it grew in a plot of sandy loam, poorer even than that here. One can only speak of it as it really is here, as undoubtedly it is difficult to establish in many places; and could we arrive at some definite understanding of its requirements, we would be well rewarded, as such a beautiful and distinct plant is worth a good deal of trouble to succeed with.—S. ARNOTT, *Sunny-mead, Dumfries.*

Ceanothuses Under Glass.—At no time were hardy shrubs forced prematurely into bloom as popular for indoor decoration as they are now, while the list of subjects so treated has of late been considerably extended. Some of the *Ceanothuses* are admirably adapted for the purpose, and what is decidedly in their favour is that in their charming tone of blue they stand out quite distinct from any of their associates. They do not readily lend themselves to hard forcing in the same sense as Azaleas or Lilacs; but brought on gently under glass they may be had in flower by the end of March or early in April, when, as the lighter tints greatly prevail among forced shrubs, they are, from their distinct shade, of considerable value for grouping purposes. When intended for forcing, they are best confined altogether in pots and plunged out of doors in a sunny spot during the summer months. At that time they are greatly benefited by an occasional dose of liquid manure. Of the different kinds that may be treated in this way, *Ceanothus dentatus* and *C. veitchianus* are two of the best. Both of these may be readily propagated by means of cuttings, and plants obtained in this way flower in a comparatively small state.

A Beautiful Exhibit of a Charming Annual.—A most noteworthy exhibit at the meeting of the Royal Horticultural Society on June 4, though by no means a very extensive one, was a collection of the different forms of *Nemesia* shown by Messrs. James Veitch and Sons of Chelsea. Some of the most distinct varieties were represented by about a dozen plants of each—a good idea, as in this way the general effect could be seen to advantage and comparisons between the different forms carried out without difficulty. Particularly striking were the plants of Orange Prince (with comparatively large flowers of an intense deep orange colour), Blue Gem (a charming form with flowers at a little distance suggestive of the *Forget-me-not*), White Gem (a pure white counterpart of the preceding), and bicolor (in which the upper part of the flower is light blue with a white lip). Under the name of Yellow Gem the plants shown were less uniform in colour than the two other Gems previously mentioned, but all were extremely pretty. Among the mixed colours, some of the scarlets and carmines stood out most conspicuously, though all were so beautiful as to render a selection a difficult matter. What is more, in viewing such masses of flower it was hard to understand that each consisted of but a single plant, as a close examination revealed. The plants, which were grown in the orthodox 4½-inch pot, or one 5 inches in diameter, had been stopped twice during their earlier stages in order to induce a bushy habit of growth, which treatment was conclusively proved to be most satisfactory. At all events, the charming selection of varieties and the high state of culture manifest in the condition of the plants were both worthy of record.—H. P.

A Seedling Loquat.—When passing through Italy a few years ago, I purchased some of the fruit of the Loquat, *Eriobotrya japonica*, at that time in season. The plant with its fruit shown in the illustration, the offspring of one of the seeds of such fruit reared in a cool greenhouse, may be of interest to some of your readers.—(Miss) E. R. TAYLOR, *Old Charlton*.

Cineraria Matador.—Those who have grown this beautiful *Cineraria* will be able to endorse every word that has been written in its favour on page 189, April 20 issue. For decorative purposes where a mass of colour is wanted the scarlet *Cineraria* has few equals. The variety can be relied on to come true; out of a batch of about seventy plants there were only two or three not up to the standard. Although introduced under the above name, I believe the same thing is offered as *New Scarlet*; at any rate, there is little or no difference in the colour of the flowers.—H. S. WARGRAVE.

Growing Wild Strawberries in Pots.

—The following note may interest some readers of *THE GARDEN*. Two years ago, while staying for a few days in Cheshire, I gathered some ripe wild Strawberries off plants growing on dry hedge banks. The fruits were very sweet, and for the novelty of the thing I brought a few roots away with me to the South of England. These roots were potted in 3-inch pots, and have remained in them ever since. Last year the plants bore a few fruits, which were very sweet and of fair size. This year the plants were placed in a vinery in March, and they have done remarkably well, although not specially attended to. Several dozens of fruits are borne on a plant, and they are as large again as when ripened in their natural state. The plants would, no doubt, do better still if they were re-potted and well cultivated. A lady to whom I gave a few fruits the other day said, "I had no idea that the wild Strawberry so grown would be so sweet."—G. G.

Primula farinosa.—The admirable way in which so many plants of the dainty native *Primula farinosa* were exhibited at the International Horticultural Exhibition by the Craven Nursery must have brought home to *Primula* admirers how beautiful this native plant really is, and how worthy it is of having its successful cultivation understood.

It is but seldom, save in its native habitats, that we can see it in such quantity in bloom, and when growing at home the plants are not, as a rule, so close together. It has already been so much discussed that the treatment it requires may not be considered worthy of additional space; but I am confident that the many who saw *P. farinosa* at Chelsea, as shown by the nursery named, will anxiously desire to own and to grow it well. It does not appear to object to wet in winter, provided the soil is well drained though moist; but the writer finds that it is desirable to give it plenty of water after it makes growth. Some lime, in the form of limestone chips or old mortar, has given additional vigour here, and in association with a soil of grit and loam, with a surfacing of chips, has given an excellent bloom this season.

The Summer Snowflake in Water.—At this season, when we are in possession of the flowers of the Summer Snowflake, *Leucojum aestivum*, it is well to consider how we can accommodate it in our gardens so as to give the best possible effect. In ordinary border cultivation it is a poor plant, so far as its habit is concerned, as the stems are too long for the size of the flowers, and the effect is far from good. In long grass it looks very well, but nowhere have I seen it look so pleasing as in about six inches of water, where it is not only prettier, but appears to thrive better than in any other place. I first saw this method followed at Mount Usher, where the late Mr. George Walpole pointed it out to me in such a situation—a small pond. Growing there in water, the leaves were

A SEEDLING LOQUAT IN A READER'S GREENHOUSE.

more handsome and the flowers finer. Those who have no water in their gardens should grow *L. aestivum* in moist soil and through other herbage, which would take at least 6 inches off the bareness of the stems.—S. ARNOTT, *Dumfries*.

FORTHCOMING EVENTS.

June 18.—Royal Horticultural Society's Meeting and Gladiolus Show. Lecture by the Rev. Professor Henslow on "Professor J. S. Henslow as Ecologist." Preston (Somerset) Gardeners' Association's Meeting.

June 19.—Yorkshire Gala (three days). National Hardy Plant Society's Show at the Royal Horticultural Society's Hall, Westminster. Jersey Rose and Sweet Pea Show (two days).

June 20.—Linnean Society's Meeting.

THE ROSE GARDEN.

THE UNRELIABILITY OF ROSE SPORTS.

SOME varieties of Roses sport very freely. For instance, Catherine Mermet has given us three that are really grand, viz., *The Bride*, *Bridesmaid* and *Muriel Grahame*. These sports would appear to be better fixed or more certain than many. Those from *Caroline Testout*, too, seem to come more true than most. I have had *Augustine Guinoisseau* carry flowers of *La France*, the variety it sported from. But the sports from *Comtesse d'Oxford*, viz., *Pride of Reigate* and *Pride of Waltham*, are very uncertain. I have frequently discovered two upon the same plant simultaneously. Another example occurs to me, and that is the two sports from *Heinrich Schultheis*—*Merrie England* and *Mrs. Harkness*. *Heinrich Schultheis* also sported its soft blush variety at two places simultaneously, and *Paul's Early Blush* is generally conceded as the prior name instead of *Mrs. Harkness*. I am sorry to say there is no reliability in these sports, or *Merrie England* would be our best striped Hybrid Perpetual.

Sir Rowland Hill sported from *Charles Lefebvre*, and when it comes true we have no other Rose that approaches its deep and yet clear port wine colour shaded with maroon; but we cannot depend upon it—in fact, not half of my flowers are of the desired colour. However, the blooms are always good, for they are either *Sir Rowland Hill* or *Charles Lefebvre*, and a better dark Hybrid Perpetual it would be difficult to select.

Then there are many climbing sports that have come from what were quite dwarf growers in their normal condition. Climbing forms can now be had of *Kaiserin A. Victoria*, *Mrs. W. J. Grant*, *La France*, *Caroline Testout*, *Cramoisie Supérieure*, *White Pet*, *Devoniensis*, *Lady Ashtown*, *Liberty*, *Papa Gontier*, *Niphetos*, *Perle des Jardins*, *Souvenir de la Malmaison* and others. The unreliability of these is very marked. Often we can find a plant quite as dwarf in habit as the variety was when first introduced. Even buds worked from the same shoot have produced both dwarf and climbing forms.

When we come to the *wichuriana* we find *Dorothy Perkins*, to take only one example, producing many sports. Two very good ones have originated in our gardens. *White Dorothy* has more than once had the true *Dorothy Perkins* upon it, and what is even more remarkable, there have been distinct flowers in the same trusses of bloom.

Baroness Rothschild has given us *Merveille de Lyon*, *Merveille de Blanches* and *Mabel Morrison*, which keep as true as any among the Hybrid Perpetuals. Unfortunately, they are also minus perfume, or they might have some slight chance with that grandest of white Hybrid Perpetuals, *Frau Karl Druschki*, which, again, is minus fragrance.

Etienne Levet, *La Reine*, *Eugène Fürst*, *Baronne Prevost*, *François Dubreuil*, *Francisca Kruger*, *Bougère*, *Duchesse de Morny*, *Sunset*, *Mme. Falcot*,

Papa Gontier, Anna Olivier, Mme. Masson, Maman Cochet, Phyllis, Mrs. W. J. Grant, Mme. Willermoz, Suzanne M. Rodocanachi, Mme. Cusin, Conrad F. Meyer, Kaiserin A. Victoria, G. Nahonnand, Souvenir d'un Ami, Perle des Jardins, Lady Mary Fitzwilliam and General Jacqueminot all have the sporting character, and have already given us some good and distinct Roses. I have not exhausted the list in the foregoing, and perhaps there may appear little purpose in these notes; but I wished to show how easy it is for one to imagine he has a wrongly-named plant when the fault really lies in the reversion to the normal variety.

Sussex.

A. P.

THE NAMING OF ROSES.

AN American horticultural paper announces in its advertisement columns an offer of a prize of one hundred dollars for a name to be given to a new seedling Rose, which is said to possess all the good qualities of a red Rose from a commercial florist's point of view. I should say the competition is only open to florists, private gardeners and others engaged in horticultural work residing in the United States and Canada.

This offer is made by A. N. Pierson (Inc.), Cromwell, Conn. This certainly is one method of booming a Rose, but I do not suppose English or Irish growers have so exhausted their resources for names that they will copy our American cousins.

While upon this subject of names, I would enter a friendly protest against the practice adopted by American florists in giving other names to well-known Roses. For instance, they now call Antoine Rivoire by the name of Mrs. Taft. This would be bad enough if there was not already a Mrs. Taft among the dwarf-growing Polyantha Roses; but I think all Rose-growers will agree with me that such a practice is likely to lead to great confusion. They have already given the name of American Beauty to a Rose whose correct name is Mme. Ferdinand Jamin, and there may be others. I trust this practice will be stopped, or certainly not countenanced by

responsible growers. We warmly welcome American novelties, and look forward to the pleasure of making the acquaintance of some of them. One named Madison should be a real winner, judging from its illustrations. It is a pure white flower, like The Bride, with foliage resembling Holly. It is said to be a splendid free-blooming Rose, and will produce a crop every five weeks in midwinter over there. This is not to say the variety will do the same here with our average sunless winters, but it should be a real beauty for spring flowering, also for outdoor work.

Eastwood, Essex.

WALTER EASLEA.

ROSE GROSSHERZOG FRIEDRICH.

THIS charming Hybrid Tea, which Herr Peter Lambert has given us, is a worthy introduction of the raiser of Frau Karl Druschki, Gustav Grünerwald and others. Its parentage is given as Caroline Testout crossed with Meta, that superbly-coloured Rose of Messrs. A. Dickson and Son's raising, and one may see in the bloom of the Rose under notice quite a distinct golden hue at the base of the petals. Its colour is of a rosy vermilion tint. Under glass it is particularly pleasing, the clearness of tint with a yellowish hue pervading the flower,

AN EXQUISITE HYBRID TEA ROSE: PHARISAER.

giving it quite a distinctness so much desired at the present day. I think we shall find Grossherzog Friedrich to be a real good thing. P.

HYBRID TEA ROSE PHARISAER.

IN this variety we have a very beautiful Rose, most accommodating in its requirements, for it is alike excellent under glass and out of doors. It is a variety well known to exhibitors and worthy of a place in every collection as a garden Rose. In colour the flowers are very white, deepening in the centre to salmon rose. The flowers are large and the buds long. It is not one of the "fair weather" Roses, since the fine long buds open well in inclement as well as in fine weather.

THE FLOWER GARDEN.

SEASONABLE NOTES ON CARNATIONS.

Planting Seedlings.—This is one of the important tasks of the moment. It is, of course, well known that comparatively few of those amateurs who grow Carnations and Picotees hither about the cultivation of plants from seeds; they are content to have the superb flowers from the many magnificent varieties which the skill of the florist has placed

at their disposal, but one cannot say that this is altogether wise. The raising of plants such as these from seeds has a fascination which grows on most people, and intelligent, maintained efforts are sure to be handsomely rewarded sooner or later. I do not suggest that amateurs should invariably trouble about cross-fertilisation; they seldom know the best lines on which to proceed, and consequently their successes are few and far between; but men like Douglas and others offer seed from their own strains, and something meritorious, if not of outstanding excellence, is sure to come from every packet of seeds. Let the soil be well prepared for the young plants. Dig it deeply and thoroughly, and do not omit to incorporate with it some sweet leaf-mould or refuse manure, as well as crushed mortar or lime rubbish. To achieve the best results the soil should be friable to a depth of not less than 18 inches, and if more, so much the better.

Mulching.—As an aid to the retention of soil moisture, to keeping the ground pleasantly cool, and to conveying a little food at a time when it will most certainly be appreciated, mulching with short manure is invaluable. It is by no means uncommon for the material to be spread much earlier in the season than this, and usually to decided advantage, but its food properties will have gone by now, and those who are able to rake it off and put on fresh manure ought not to hesitate to do so. The soil must be carefully hoed, or pricked over with a small fork beforehand, and then a thin covering of the manure spread down. It must be short and

always loose to facilitate the free passage of water and air, or the benefits derivable from it will be much reduced.

Earwigs.—It may be well to remind the reader that one of the worst enemies with which he will have to contend when the plants are in flower are earwigs. They have a vicious habit of getting into the body of the flower, and it is not long then before they do irremediable damage. It is unfortunate that there is nothing really practical that can be done in the way of prevention, and incessant observance, with a view to instant destruction, should be the order of the day. Trapping must, of course, be done as far as possible, but conspicuous traps, such as are permissible among the

luxuriant-growing Dahlias, would not be tolerated for a moment in Carnation-beds. Pieces of dried moss or hay in small pots can be employed, but too much reliance must not be placed upon them, or disappointment is bound to come later.

Disbudding.—At the end of this month and during July we look forward to enjoying the beautiful reward for our labours in the past few months, and a decision must be come to immediately, if it has not been done before, as to the degree to which disbudding will be carried. As I said in my previous notes, I am generally in favour of the retention of three buds on a stem, but fewer or more may be chosen according to the fancy of the individual grower. As far as one can judge, each bud selected for development must be perfect, and some consideration ought to be given to their disposal on the stem, as when badly placed the artistic effect is not so good.

Morning Syringing.—Experience has proved to me that syringing in the early hours of the morning is especially beneficial to the plants in more ways than one. A great advantage lies in the fact that the probability of either green fly or thrips becoming dangerously numerous is reduced to the minimum, while the "grass" is assisted in no small degree, which means that there will be superior shoots for layering down when the time arrives to do such work next month. It cannot be doubted that either of these reasons alone justifies the labour and trouble involved in the operation, while there is the further merit of keeping the foliage clean and more attractive. F. R.

THALICTRUM ANEMONOIDES.

VERY much resembling some of the Anemones in flower, this charming little plant is one of the most distinct members of the Meadow Rue family. It is quite a contrast to the taller-growing kinds, some of which attain a height of 6 feet or more, barely being more than 6 inches high when full-grown. Coming into flower in April, or even in March, it is a useful plant for the alpine-house, succeeding well in pans, or, for the shady and sheltered parts of the rock garden, in light, rich soil. It is one of the few members of the genus which have distinct and showy petals, and is a North American plant, usually found growing in open woods and shady places. During the last few years we have had some valuable additions to this genus in cultivation from China, of which the most striking and attractive is *T. dipterocarpum*. This plant grows to a height of 5 feet or more, with a large inflorescence of rose purple flowers, the citron yellow anthers forming a beautiful contrast. Rather smaller in habit, with similar flowers, is *T. Delavayi*, from the same region. Some of the forms of *T. minus* make elegant little tufts of finely-divided, Fern-like foliage, very useful for table decoration with cut flowers. A plant that is worth a place in any garden is the handsome *T. aquilegifolium*, which grows about three feet high, with very attractive foliage and panicles of pale feathery-like flowers. Of this species there are other varieties, one, with dark purple stems and flowers, being called *Thalictrum aquilegifolium* variety *atropurpureum*. Of the taller-growing kinds, like *T. glaucum*, there are many, and they make excellent subjects for the wild garden or water-side. All may be increased by division in spring or autumn, or raised from seeds which are freely produced. W. I.

THE KITCHEN GARDEN.

TOMATO PLANTS OUT OF DOORS.

DURING the last few seasons many amateurs have undertaken the cultivation of the Tomato outdoors. The results have been good in many cases, considering the somewhat unfavourable weather experienced during the past summers. In the most favoured districts the plants require every attention to induce them to yield a fair crop. In cold, wet districts their cultivation outdoors cannot be recommended. Some fruit may be produced, but it is almost impossible for it to ripen under these conditions. The fruit in an unripened state is used for certain culinary dishes, and providing the aim is to produce fruit of this description, many growers in unfavourable districts plant in the most sheltered quarter at command. Endeavour to procure strong, short-jointed plants. If the plants are home-raised, so much the better. Keep

GROWING TURNIPS ON CLAYEY AND LIGHT SOILS.

SOME cultivators advocate the culture of Turnips in very firm soil. This is good advice when applied to soil of a light, sandy nature; but where clayey soils obtain it is a mistake to make them very firm. I have had to deal with the cultivation of large breadths of Turnips in both kinds of soils, and after a small experiment came to the conclusion that I could grow better roots in unfirmed, heavy soils than in those made quite firm by treading. Furthermore, I found that the roots swelled and were fit for table about a week earlier in unfirmed ground than in well-trodden borders. Both air and warmth penetrated the unfirmed soil and thus hastened growth. I have heard cultivators say, "Oh, it is necessary to have firm soil to produce nice roots with single tap roots attached." I have not found this to be a correct view in heavy loams, but I have noticed that certain varieties, and the best strains of them, grew perfect in form in unfirmed ground.

THALICTRUM ANEMONOIDES, A NORTH AMERICAN SPECIES WITH ANEMONE-LIKE FLOWERS.

the plants to one stem by taking out all side shoots as they appear. Do not overcrowd them.

Warm, sunny positions are most suitable, on a south wall or fence if possible. Secure the plants firmly, but allow plenty of room for the stem to swell freely. Attend to the pinching out of all side shoots. Give water when needed, and when three, or, in favoured localities, four, bunches of fruit have set, stop the plant by pinching out the top. Diluted manure-water applied occasionally will assist the plants to swell their fruit. By cutting off a portion of the foliage, sun and air gain free admission to the fruit. This operation is sometimes carried too far; cases have been known where every leaf has been ruthlessly cut from the plants even before the fruit is set. I have known blackbirds to attack the fruit when colouring. Varieties of Tomatoes are numerous. For outdoor planting, Holmes' Open Air, Winter Beauty and Satisfaction have proved excellent. COLIN RUSE.

The Turnip fly is much more troublesome in some districts than in others. The flies do not like turpentine. If a wineglassful be well mixed with two gallons of water and syringed over the bed when the weather is dull, the insects will not attack the leaves to any serious extent. Frequent hoeing of the soil between the rows with the Dutch hoe is most beneficial where Turnips are grown in heavy soils; but undue trampling upon the ground must be avoided.

In light soils the early crops do well enough if the fly be kept at bay; but in the case of succeeding crops I advise inexperienced cultivators to put on a thin mulch of well-rotted manure, for this is of great advantage to the growing crop. It is a very common occurrence in summer-time to find Turnips exhibited which are too pithy to be fit for table use. Furthermore, I have noticed that nearly all such specimens have been grown in light, sandy soil; but where the rich surface mulch has been put on, the plants have been tided and the roots quite tender. B.

THE GREENHOUSE.

THE BEST CROTONS.

THESE are grown with a view to tide over a time when cut flowers are scarce, and during the dull months they are delightful for house decorations. Plants in small pots can be used with great taste in the drawing-room or library at all seasons, and they are particularly useful for jardinières which will hold three or four or half-a-dozen plants, or they can be most advantageously used in large or small bowls for the dinner-table. There are some really brilliant colours among them, and if a good batch is raised every year, some nice plants are always available, even in 3-inch pots. These are best when the tops are what is termed "ringed," that is, the top rooted before being taken away from the plant. This is best done by preparing some peat and sphagnum moss, and after an incision is made with a knife around the bark, this material should be bound tightly around and kept well sprayed till roots are emitted through the moss all round. This does not take long if the plant is healthy and the moss kept damp. On no account must it be allowed to become dry.

The plants should then be taken off and potted immediately, placed in a small propagating-case and kept moist and close for a week or ten days, when they will be established. At no time should these plants be overpotted; it is really surprising how big a plant can be grown in a small pot with care in watering and feeding. On the other hand, it is notorious what wrecks can soon be made of them by injudicious handling.

Very good varieties are among the following. Some well-known old favourites still hold their own when well grown. Queen Victoria, orange yellow, broad leaves; Lucy, narrow, twisted leaves, green and crimson; Weismannii, long, drooping leaves, variegated green and yellow; Warrenii, long leaves, remarkably twisted, like a corkscrew, yellow and red; Elysian, long, narrow leaves, lemon yellow and rose, very handsome when well coloured and grown; Laingii, narrow leaves, stems and footstalks red and yellow; Mrs. Dorman, yellow and crimson, very conspicuous; Aigburth Gem, leaves crimson and narrow; Mrs. Luther, narrow red leaves and of fine habit; and Souvenir de Thomas Rochford, bright red and very graceful foliage. W. A. Cook.

The Gardens, Leonardslee, Horsham.

THE SUMMER TREATMENT OF BOUVARDIAS.

MANY Bouvardia plants are spoiled every year through subjecting them to too much heat and confining them from the air. Stunted, sickly

plants in large pots may sometimes be seen in a warm greenhouse. Such specimens are not worth retaining, and should be discarded at once, as it is almost impossible to bring them to a normal state of health again. From about the middle of June to the middle of September the plants do remarkably well planted out in open borders. They must be lifted and carefully repotted, and be placed in frames before the earliest frosts come. If cultivators cannot find it convenient to plant out the Bouvardias, they should plunge the pots in the border and leave them there during the period named. The soil in the border must be well

is a wise plan to stop as early in the season as possible; then the resultant new ones will have ample time to become strong and ripened. Wonderfully fine plants may be grown in the way described in one season, and bear extra large trusses of flowers. AVON.

A BEAUTIFUL WHITE-FLOWERING CACTUS.

(*CEREUS AMECAMENSIS.*)

FEW, if any, of the exhibits brought before the floral committee at the meeting of the Royal Horticultural Society on May 14 attracted as much attention as did this delightful member of the Cactus family, of which flowering examples were shown by Mr. A. Worsley of Isleworth. A cut branch was exhibited, and, judging by its appearance, the plant is, I should say, in common with other members of the genus, of a rambling habit of growth. On the specimen shown, which was about four feet in length, there were two clusters of flowers, one at the top and the other near the bottom, apparently at a joint. There were five flowers or buds in each cluster, so that it would appear to be, when fully established, decidedly free flowering. The expanded flowers are 8 inches to 9 inches in diameter, and of the purest white, except a slight green suffusion just in the centre. The petals are much pointed, hence the whole contour of the flower is very different from that of the Phyllocacti, which, in many gardens, are the only Cactaceae plants grown. A few such exhibits as this *Cereus*, and a noble *Phyllocactus* which was shown at the same time, should serve to rescue some of these delightful flowering plants from the obscurity into which they have now fallen. H. P.

A BEAUTIFUL WHITE-FLOWERING CACTUS (*CEREUS AMECAMENSIS.*)

HOW TO GROW THE STREPTOCARPUS.

MANY greenhouses and conservatories attached to dwelling-houses are partially shaded, and, of course, in such structures it is a very difficult matter to keep up a continuous display of flowers, as many kinds will only bloom sparsely in the circumstances. The *Streptocarpus* will, however, grow and flower

freely in partial shade. The plants are, moreover, very suitable for placing in groups on the floor of a house; and as there has been a great improvement in the strains during the past few years, there is added inducement to grow a batch of plants. The resultant seedlings from seeds sown early in the spring are now well advanced, and they must be given pot culture. It is not wise to disturb the seedlings too soon, because, as a rule, they form one large leaf first, and it is immediately under this leaf that the strongest roots grow. If lifted from the seed-pan too soon, the growth of the large leaf and the roots is arrested for a time.

It will be advisable to stop the shoots at least once while the plants are growing in the open air. The longest shoots must be stopped first, and it

These plants will flower during July, August and September; but it is best to pinch off the flower-stems from a certain number of the plants, and so secure extra fine flowering specimens the next year. The best compost is one made up of fibrous loam two parts, leaf-soil one part, sand and rotted manure one part. Use very clean pots and crocks, and press the soil gently around the roots of the young plants so as not to bruise them. Give water at once; then place the plants on a bed of ashes or shingle on the stage of a greenhouse. After the first watering be very careful not to apply too much, but on every fine day syringe the pots on the outside twice; this treatment induces quick root-action. Repot the plants as required, and those denuded of their flower-stems for next year's display must be grown in a cool frame during the months of July, August and September.

SHAMROCK.

TREES AND SHRUBS.

HARDY AZALEAS.

IT is difficult to imagine a more pleasing feature than a well-placed and well-flowered group of hardy Azaleas, for the colours of the flowers are so bright and varied that they appeal to everyone, while they retain a delicacy which does not offend the most sensitive nature. In addition, the majority are deliciously fragrant, their perfume scented the garden for a considerable distance.

Unfortunately, they are not everybody's plants, for they may only be grown successfully in places where lime is not prevalent in the soil to any great extent. Azaleas at Kew have for long been one of the fairest features of the Gardens, and many a pilgrimage is made annually for the purpose of seeing them in flower. There they are massed in large beds on a lawn amid groups of mature Beech and other trees, the surrounding greenery providing a fitting setting for the central mass of flowers. Very effective also are the Azaleas at Leonardslee in Sussex and Penllergare in South Wales, where they form an extensive undergrowth to woods of Pine and other trees. Various other gardens also about the country owe a good deal of their May beauty to hardy Azaleas, and a glance at the accompanying illustration will be sufficient to show how fine these plants are in the Japanese garden at Gunnersbury House, one of the seats of Mr. L. de Rothschild.

Azaleas are no new addition to the occupants of the garden, for in some establishments they were as popular thirty or forty years ago as they are to-day; but many more people are now taking advantage of their decorative qualities than at any time in the past, and there are few gardens of any pretensions which do not include representatives of the group. The majority of the kinds grown are hybrids, the species from which they were raised being rarely met with outside botanical establishments. Several North American species and one from the Caucasus formed the basis for the early operations of the hybridist, while more

recently a species from the Far East has been made use of. Continental growers were most conspicuous in the raising of new varieties in the early days, the nurserymen of Ghent being particularly successful, so much so, in fact, that the whole group of hardy Azaleas came to be known as Ghent Azaleas, a name which is retained in some quarters to the present day. Very little behind the Ghent raisers were several English firms, Messrs. Waterer of Knap Hill and Messrs. Cripps of Tunbridge Wells being among the pioneers in the movement, and to these firms we are indebted for some of the handsomest kinds. Messrs. Waterer being specially interested in the raising of red and other rich-coloured flowered kinds. In the early days many of the varieties or hybrids were given distinctive names, and even now such

or so later, their best time being mid-June. Crossed with other varieties, a number of late-flowering kinds have been produced which prolong the flowering season over a period of several weeks. *A. viscosa*, the Swamp Honeysuckle of North America, is the latest of all to bloom, its flowers often being in good condition in July.

The Caucasian *A. pontica*, which is correctly *Rhododendron flavum*, is a free-growing, fragrant, yellow-flowered species. Crossed with *A. calendulacea*, it has produced a number of the more vigorous yellow and orange coloured kinds. It blooms with *A. calendulacea* and *A. nudiflora* in May.

From China and Japan we have the highly ornamental *A. sinensis*, or *A. mollis* as it is frequently called, which has become so popular of

AN EFFECTIVE GROUP OF AZALEAS IN THE JAPANESE GARDEN AT GUNNERSBURY HOUSE, ACTON.

kinds may be obtained; but, as a rule, it is not necessary to purchase named sorts to form a showy collection, for among mixed seedlings all sorts of coloured flowers may be obtained. Some nurserymen make a speciality of one or more particular kinds; others cultivate all sorts.

The American species which have entered into the production of the garden Azalea are *A. nudiflora*, *A. calendulacea*, *A. occidentalis*, *A. arborescens* and *A. viscosa*. Of these the former two have taken a greater part than the other three. From *A. nudiflora* many white and pink kinds and varieties with delicate shades of colour have been obtained, whereas the blood of *A. calendulacea* can be traced in sorts with red, scarlet and orange scarlet flowers. *A. occidentalis* and *A. arborescens* have white or pink flowers. They are taller and more upright in growth than the other kinds, and bloom a fortnight

late years for forcing. The flowers vary in colour from cream to orange and from pink to scarlet and red. The various varieties may be distinguished from the American and Caucasian kinds by reason of the larger and more shapely flowers and the absence of fragrance. Blossoming earlier than the other kinds, it is less useful for general outdoor work, for the flowers are sometimes killed by late frosts. Hybrids are, however, being raised between it and later kinds which stand better. Nevertheless, it is a most beautiful and popular kind for forcing.

In addition to the value of the flowers, Azaleas have another asset, for the foliage colours brilliantly in autumn. Although still spoken of as Azaleas, all these plants are now, strictly speaking, *Rhododendrons*, Azalea not being a recognised genus.

WHITE LILAC WITH DOUBLE BLOSSOMS.

A VARIETY of the Lilac with double white flowers is mentioned by Loudon, but for the improved varieties of the present day we are indebted to the firm of M. V. Lemoine et Fils, Nancy, France. It is now about thirty years since M. Lemoine distributed the first of his seedlings, and from that time onward numerous varieties have been sent out from the same source. Of the white-flowered kinds, that herein figured, Miss Ellen Willmott, is remarkable for the large size of its individual flowers, and as they are borne in massive trusses and the habit of the plant is all that can be desired, it deservedly occupies a foremost place among double-flowered Lilacs. This variety is at present not very generally known, though it was first sent out in the autumn of 1903, the price then being eight francs each. Of the older kinds, the first place must, I think, be assigned to Mme. Lemoine, which before the advent of Miss Ellen Willmott was looked upon as possessing every desirable feature.

THE DOUBLE-FLOWERED WHITE LILAC: MISS ELLEN WILLMOTT.

It is now largely grown for forcing purposes, for which it is well suited, as it may be readily flowered in a comparatively small state. It is, moreover, a very handsome shrub, as a well-balanced specimen, about fourteen feet high, near where I am writing will testify. Other good double whites are Mme. Abel Chateau and Mme. Casimir-Perier. H. P.

THE BEST MAGNOLIAS.

THE early-flowering Magnolias have been wonderfully good this season in various parts of the country. When a good selection is grown, they are extremely interesting, and extend their flowering season from March to August and September. Among the first to open are *M. conspicua* and *M. stellata*. These are perfectly studded with flowers, as is that rare variety *stellata rosea*. *M. alba superba* and *stellata* are fine for massing, and are used as such, their appearance when in bloom being splendid and resembling a bank of snow, especially when an evergreen bank of shrubs is provided as the background.

M. Campbellii is the first to open, but this is only supposed to do well in favoured districts. It does well here, and my impression is that it does not flower till it arrives at a mature age.

Other good varieties are: *M. acuminata*, which forms a tree very quickly. *M. cordata*, a North American species with yellow flowers about three inches to four inches across, is not such a free bloomer. *M. Lennéi* is a favourite, and flowers in April and May, a rich purple colour. *M. macrophylla* has enormous leaves, 2 feet long, with bell-shaped flowers of great size. *M. parviflora* has beautiful white flowers, with red stamens when the flowers are open. *M. soulangeana* and *M. s. nigra*, very dark purple. *M. tripetala*, a North American species with huge leaves and white flowers. *M. Watsonii*, similar to *M. parviflora*, but with larger blooms and very sweet-scented. *M. glauca*, a North American species, is nearly evergreen, and its creamy white flowers are produced all through August. It is sometimes called the Swamp Magnolia, as it does best in a

HYDRANGEA PANICULATA.

This hardy Japanese species is of more than ordinary value in gardens, as the flowers are not only very showy, but are produced during August and September. Compared with the months of May and June, this is a dull season with flowering shrubs in the pleasure grounds. To obtain the best results good cultivation and fairly hard annual pruning are necessary, as, when allowed to grow naturally, the panicles of flowers are much smaller, although more numerous. To obtain large panicles 1 foot in length and 6 inches to 9 inches through, fairly hard pruning is necessary in February or March. Thinning of the young shoots must also be practised, leaving only from six to ten growths to mature, according to the size of the plants. In numbers the fertile blossoms far exceed the sterile ones, but there are ample

of the latter an inch across clothing the panicles. If anything, the combination of the two renders the inflorescences more attractive than otherwise. The colour of the flowers is creamy white. In gardens the variety *grandiflora* is more generally met with than the species, being extensively grown in pots for greenhouse decoration. It is also valuable for the outdoor garden, and differs from *H. paniculata* by producing nearly all sterile flowers, while the flowering season is a month or six weeks earlier. Hydrangeas delight in a well-worked, rich, loamy soil, with a mulching of good manure applied in June. Propagation is by cuttings. A. O.

THE FRUIT GARDEN.

THE STONING AND SCALDING OF GRAPE BERRIES.

WHEN an amateur cultivator has done all he could to produce a fine crop of Grapes on his Vines, he feels greatly disappointed if many bunches are spoiled through the scalding of the berries. Some varieties scald sooner than others. The berries are most likely to scald just at the time when the stones are hardening. Directly the berries have set, a closer atmosphere must be the rule until that stage when the stones in the berries commence to harden. The hardening of the stones begins, in the case of the varieties Buckland Sweetwater, Foster's Seedling, Black Hamburg and Madresfield Court, about six weeks after the flowering stage. Alicante, Muscat of Alexandria, Gros Colman and other late-keeping varieties are about ten days later in hardening their stones. The guide here given will be helpful to inexperienced cultivators.

Now, as soon as the hardening process begins, the berries cease to swell as rapidly as before. For about twenty days there is not much perceptible difference in their size. Up to this point the flesh of the berries is very firm, and moisture must not be allowed to settle on them in excess while the sun shines on the house.

Grapes growing in a properly-constructed vinery, when well managed, rarely scald; but Vines are grown in greenhouses and other structures which are not ideal for this particular purpose, and then, with the best possible management, some berries are lost through scalding. To prevent this loss the cultivator must do one of two things without fail, namely, open the ventilators an hour before the sun shines on the house in the morning, or at ten o'clock each night open the top ventilators about one and a-half inches wide and leave them so throughout the night, increasing the ventilation before seven o'clock the next morning.

Any moisture lodging on the berries will be dispersed before the sun gains much power, and the atmosphere generally will be drier. Many berries are scalded which are never exposed to the direct rays of the sun. This is caused by a close, moist atmosphere in the house while the sun is shining brightly on it. Very early closing in the afternoon has the same bad results. Directly the berries soften naturally, the last swelling commences, and there will be no more scalding unless the house is kept closed in the daytime when the sun is shining. Ripening Grapes need a good circulation of warm air about them. No feeding must be done while the berries are stoning, but the soil should be kept in a uniformly moist state. AVON.

GARDENING FOR BEGINNERS.

A PLANT FOR THE AMATEUR'S GREENHOUSE (*CELSIA CRETICA*).

ALTHOUGH this plant has been known in the British Isles for a very long period, it is only of late years that it has become generally popular, its presence at an earlier date being almost wholly confined to those gardens where botanical collections were encouraged and plants were grown as single specimens, or in small numbers at the best, rather than as large groups. The advent of the grouping or massing system in gardens led to many plants showing themselves to better advantage than had been possible before, and *Celsia cretica* for one proved itself to be a really valuable decorative plant.

Although it may be grown out of doors during summer, it cannot be called a thoroughly hardy plant, and it is perhaps of more general usefulness for greenhouse decoration than for the embellishment of the outdoor border. It is a native of the Mediterranean region, and is strictly a biennial, although it may be treated as an annual. In general appearance some resemblance is noticeable to a dwarf *Verbascum*, the flowerless plant being represented by a rosette of green, strap-shaped leaves. As flowering-time draws near, the inflorescence appears from the centre of the leaves, and eventually rises to a height of 2 feet to 3 feet, bearing a profusion of showy, yellow flowers, the whole inflorescence being lighter and more graceful than that of a *Verbascum*.

Propagation.—This is confined solely to seeds, and by making sowings at intervals of six weeks a succession of flowers may be kept up over a considerable period. Plants from seeds sown in May ought to blossom during the following February if grown indoors, while plants from seeds sown at the end of July or early in August, and kept growing quietly, would be in excellent condition for planting out of doors when all danger of frost had gone in spring. By sowing seeds indoors in February, flowering plants for the greenhouse can be obtained for late autumn, while the same plants can be got to blossom out of doors if kept growing vigorously. Even by sowing seeds out of doors in March, flowering plants may, sometimes be had by autumn, but, as a rule, they are less vigorous and less reliable than those which were raised the autumn before.

The Cultivation of *Celsia cretica* is not attended by any serious difficulties. The seeds may be sown in a compost composed of two parts fibrous loam, one part leaf-mould, and one part silver sand. As the seeds are very small, pass the upper soil through a fine sieve and cover very lightly. A well-drained pan or box may be used as the receptacle, and the seeds must be sown thinly. As soon as the seedlings are large enough to handle, prick them off in pans or boxes an inch apart each way. When the leaves meet, put the plants

singly in 3-inch pots, using similar soil, but replacing half of the sand with well-rotted manure, such as is taken from an old Mushroom-bed. During this time a moist greenhouse temperature may be given, taking care to provide shade when the sun is

the best plants in, for if overpotted they become unsightly. When the final pots are well filled with roots, the plants must be kept going with the use of stimulants in the form of cow-manure-water, soot-water and Clay's Fertilizer. Once a good hatch of plants has been flowered, there is no difficulty in obtaining sufficient seeds for future requirements, for seeds are produced and ripened freely. Those plants which are planted out of doors should be placed from 9 inches to 12 inches apart, according to strength, and even a little more room would not do any harm. When grown indoors, care must be taken to keep the plants clean, for they are subject to attacks of thrips and red spider, and once badly infested they rarely recover; therefore it is necessary by proper ventilation, keeping a moist atmosphere, and by careful attention to watering, to keep them in the best possible health from the seedling stage onwards.

CELSIA CRETICA, AN EASILY-GROWN GREENHOUSE PLANT.

powerful in the middle of the day. Throughout summer no fire-heat will be necessary, and even in winter, except for those plants which are coming on to flower, it is only necessary to provide sufficient artificial heat to keep damp and frost away. Thorough ventilation is, however, very necessary, and strict attention must be paid to watering. Never allow the plants to become starved, but, as soon as the pots are nicely filled with roots, repot until pots 6 inches in diameter have been reached. These, as a rule, are quite large enough to grow

THE CARE OF CARPET BEDS.

ALTHOUGH carpet-bedding is not as popular now as it was a generation ago, there are many gardens in which several beds are so filled. In the first place, the plants must be so arranged that they will form a certain design. If allowed to grow untripped, afterwards the plants would soon present an untidy appearance, the leaves of one kind or variety growing and intermixing with those of others. Timely pinching of the leaves is an essential part of the work necessary to keep the plants in proper order. There must be no indiscriminate cutting off of leaves: the ends of the leaves or young shoots must be so shortened that every plant will be confined to its proper place and still have the appearance of not having been manipulated at all. Frequent—weekly—pinching of shoots and leaves is necessary, then the foliage will always retain its rich colouring. Plants allowed to grow too long before they are pinched get coarse and lose their colour very much. Odd, coarse plants must be removed altogether, and the gaps made filled with others from the reserve stock. It is always a wise plan to retain a few specimens in case they may be required at some future date.

HOW TO GROW BIG ONIONS.

A VERY large Onion, if flabby and not very firm, is really worthless. Hundreds of cultivators strive to grow big Onions, and the latter are useful for several

purposes if they are firm and well ripened. Some persons bend down the necks of Onions in order to make them bulb more quickly. It is never necessary to depress the tops of well-grown plants—they will ripen in due course naturally; and if bent too soon and violently, the inside scales are broken and the plant commences to produce young tops again vigorously. Of course, when this happens, the Onion is ruined. Keep the surface of the bed hoed and well mulched with rich manure.

SHAMROCK.

GARDENING OF THE WEEK.

FOR SOUTHERN GARDENS.

Plants Under Glass.

Liliums.—Keep the growing plants well supplied with water, and where the varieties are only in 5-inch pots, liberal quantities will be needed of properly-diluted farmyard manure, alternated with some good artificial fertiliser. The varieties of *L. lancifolium* are especially adapted for small pots, and their usefulness when so grown for house decoration is greatly enhanced.

Francoa ramosa.—Give the flower-spikes as they extend a neat support, and see that the plants do not suffer for the want of water. A shady position out of doors or in a cold frame on a good, firm cinder basis will suit the plants admirably. Once or twice a week, when the soil is not too dry, give some diluted manure-water. Sow seed for next season's flowering plants.

Tree Carnations.—The earliest-rooted plants will soon be ready for their final shift into 5-inch or 6-inch pots. For this compost use a sprinkling of bone-meal and a little plant food, and let the compost consist principally of good fibrous loam. Pot firmly in clean and well-drained pots. For an early display the growths should not be stopped much after the end of June. Later-struck plants should be potted on as becomes necessary, and grown as sturdily and healthily as possible. If the plants through the summer months are placed out of doors, temporary protection should be afforded in the event of heavy rains.

The Shrubberies.

Laburnums.—At the time of writing these are making a fine feature, and especially the better varieties of Laburnum, which are so distinctly superior to the old variety, and eminently suited for planting as standards on lawns and elsewhere. The following few are all worthy of inclusion: *Laburnum vulgare* Alschingeri, *L. Vossii*, *L. Parkii*, *L. quercifolium* (the Oak-leaved), and *L. Adamii*, producing both purple and yellow trusses.

Philadelphus.—The Mock Oranges for late May and early June flowering are particularly attractive. A few of the better varieties should include *Boule d'Argent*, *Bouquet Blanc*, *Candelabrè*, *purpureo-maculatus* and *coronarius foliis argenteo-variegatis*, a pretty form. A few other shrubs of special merit are *Viburnum tomentosum plicatum*, *Syringa villosa*, *Cytisus andreanus*, *Tree Lupines*, *Olearia stellulata*, *Cistus* and *Helianthemums* in variety, and *Spiræa bracteata*.

Hardy Fruit Garden.

Early Cherries.—The earliest-maturing varieties of Sweet Cherries should receive copious supplies of water, and stimulants washed down will prove valuable in assisting the crop. The fruits will soon commence to colour, and, before placing the nets over the trees, all the growths required for furnishing bare spaces and extension should be carefully and neatly tied in, the weaker ones being pinched back to form spurs for fruit-buds. Discontinue the use of any insecticide when the fruits commence to change colour.

Thinning of Fruit.—The majority of the wall trees are now advanced enough to admit of a preliminary thinning where too crowded, as it is quite evident which are swelling away freely. Where the crops of Peaches and Nectarines are light, only deformed and badly-placed fruits should be removed, any final thinning that may be necessary being done after the stoning is finished. The final disbudding should be carried out and the growths neatly tied in. Continue to syringe the trees as often as possible in the morning or evening.

Hardy Vines.—These will require attention, otherwise the growth will become congested and the bunches suffer in consequence. Avoid overcrowding, neatly and firmly secure strong shoots where required for extension, and stop the laterals and thin out the bunches where too thick, leaving only one to a spur in any case.

The Kitchen Garden.

Thinning-Out of the crops should not be left longer than is absolutely necessary, and whenever possible choose showery weather, as then the

plants do not feel the disturbance at the root so acutely.

Kidney Beans.—Make another sowing of Dwarf Beans, and also one of Runners, to succeed the earliest sown, and if the ground is dry, soak the seeds for twenty-four hours before sowing to assist quicker germination. Sprinkle the young plants with a rosed can or syringe them in the evening when the weather is warm and dry. This also has a beneficial effect on the setting of the flowers.

Parsley.—Make a sowing within the next week or so for providing the supply for next winter. Assist growing plants during showery weather with a dusting of soot, and when possible aerate the surface soil with the Dutch hoe.

Celery.—Continue to take out trenches, and plant as they become ready for succession. If the ground is dry, the plants must be well watered in.

Potatoes.—Keep the ground between the rows well hoed, and earth up as becomes necessary.

The Flower Garden.

Hoing.—This is equally as important in this branch of gardening as in any other and stimulates the growth of newly-planted subjects in a marked degree; it is especially valuable where watering cannot be carried out with any degree of thoroughness, as the frequent moving of the ground forms a loose, fine surface which acts as a mulch.

Summer Bedding.—To encourage this, and to get it established as quickly as possible, the plants and surroundings should be damped each evening and the ground well watered occasionally. Complete the staking of the plants as early as possible, and to encourage growth the flowers of many things may be removed for the first week or two.

Plants in Vases.—These are usually very effective when nicely planted with suitable subjects. The root-run, as a rule, though, is limited, and coupled with the exposure to the sun and air the soil quickly becomes dry and requires constant and careful attention. E. BECKETT, V.M.H.
Aldenham House Gardens, Elstree, Herts.

FOR NORTHERN GARDENS.

The Fruit Garden.

Grafts.—These are now making growth, and where several are on one stock, the ill-placed shoots should be rubbed off and, at the same time, all the growths that have pushed on the stocks themselves.

Plums and Pears.—What is termed the breast-wood may at any time after this be removed. It is better that most of it should have been rubbed off earlier in the season, but as a rule that is neglected, and now that the rush of work for the season has lessened, it may be seen to. It is a very great mistake to shorten every shoot to a stated number of buds, because in well-furnished trees that results in overcrowding. Much to be preferred is the practice that reduced the number at once by clean excision, leaving only a sufficient number of shortened shoots to replace weakly spurs that have been removed.

Peaches.—In the North, wall trees, as a rule, do not ask in most seasons for water at the root, the Peach being an exception in some cases. Should the weather be dry, therefore, and the soil light and porous, an occasional soaking of much-diluted manure-water will be very beneficial, not only in giving vigour to the growth, but in keeping down red spider, which is often responsible for much damage to the health of the trees. Very late varieties should be lightly fruited.

Fruits Under Glass.

Lady Downe's Grape.—In thinning this variety give each berry plenty of room and leave no berries whatever in the centre of the bunches. These usually rot if left during winter.

Tomatoes.—In airy, well-ventilated structures these will require much water at the root, while in frames and low pits water must be applied with the utmost caution. Crops maturing will ripen more readily if the water at the root is limited to the merest amount necessary to keep the foliage from flagging. Late crops in cold pits should be limited to the number of trusses they are likely to bring

to maturity before November. These may be grown with the minimum of ventilation.

Cucumbers.—By removing worn-out shoots and replacing them with young ones in conjunction with means, such as repeated surfacings, of keeping up a supply of active roots, these can be kept in a free-bearing condition for a very long time. Some growers give the minimum of ventilation, but the plants seem to be less subject to collapse when judiciously ventilated in fine weather. Only a limited number of fruits should be allowed on the plants, otherwise they will exhaust themselves by overcrowding. Plants in frames may be treated in much the same manner, being particularly careful that only enough young shoots are left to fill the allotted space without overcrowding.

The Vegetable Garden.

Cauliflowers.—Sow seeds of a second-early sort for autumn cutting. In unfavourable soil sow the seeds where the plants are to remain.

Leeks.—The planting out of the main crop need be no longer delayed. Sort the plants according to size, so that the largest may be lifted for use as required. Thoroughly coat the roots with a mixture of soil and water worked into a soft mud; then lower each plant into the deep hole made with a dibber for it, so that the tips of the leaves only are seen above the ground; pour just a little water into each hole and the plants may be left to themselves. It is usual to draw deep furrows, which are afterwards levelled down when the Leeks have grown to require soiling.

French Beans.—These should be arranged so that each plant has at least one foot in the row; where closer than that, thin them, and with the thinnings make up any blanks in the rows. Runners growing as dwarf plants need much more space, and as soon as the shoots begin to run it is very important to pinch them, and to continue doing so, else they become a tangled mass which produces only a few pods compared with those that get more attention. Those trained on strings or sticks must not be stopped till they have attained the height desired.

The Plant-Houses.

Cinerarias.—The latest batch must now be provided for by sowing seeds at once. Give cool treatment throughout.

Calceolarias.—Sow seeds of these also. The seeds are so small that they must not be covered, a good way of giving the needed protection to them being to spray the surface of the compost after sowing, which settles the seeds. Then cover the receptacles and stand them in a cold frame or under a hand-glass placed in a position where the sun never reaches it.

The Flower Garden.

Watering.—If the weather be dry, Phloxes, Pyrethrums and Spiræas soon suffer; therefore apply water at once before they show signs of distress.

Pinks.—This is the proper time to propagate these by means of pipings, which are the points of the growths pulled out with a quick twitch. These are perfect without further manipulation. They root best dibbled into soil under hand-glasses the glass of which is blurred, watering the soil before placing them on; but they also root in the open, though not so expeditiously.

Stopping Plants.—There are a few desirable plants that grow so tall as to be less useful on that account. Such, for instance, are *Helianthus Golden Glow* and *H. Miss Mellish*. By topping the shoots at different times side growths are produced, the plants are dwarfer and the period of flowering is considerably extended. Some of the *Michaelmas Daisies*, if pegged down, are completely dwarfed, and such as *Aster acris* throw out innumerable flowering sprays which cover the layered stems.

Pegging.—This is as essential for some plants as staking is for others. Most of the pegs I use—and in some years there are thousands—are made of Bracken cut into suitable lengths, which are bent in the middle and both ends thrust into the ground. Next to this, Snowberry, used in the same way, makes the best peg, and is used largely for Dahlias, most of which have the shoots pegged down to dwarf the plants. *Verbenas*, *Petunias*, *Koniga variegata* and *Ivy-leaved Pelargoniums* are others which are always pegged down, but a number of plants are occasionally treated in the same way. R. P. BROTHERSTON.

Tynninghame, Prestonkirk, N.B.

THE DAFFODIL SEASON OF 1912.

ONE of the many pleasures of a gardener's life is to find a congenial soul and spend a few hours in his company talking "shop" and comparing notes. It was a happy inspiration of Mr. Robert Sydenham to allow us Daffodil people to pass the evening doing this after enjoying all the good things of his Birmingham dinner. The informal talk that takes place then is one of the pleasures we look forward to when we visit the "Midland," and such is the cast of the host's spacious net that somehow or another everyone who is "who's who" in Daffodildom finds himself in its meshes. This present year the subject chosen was "The Vagaries of the Season," and our worthy president (the Rev. G. H. Engleheart) "kicked off" with one of his typical little speeches veined with serio-comicality and deep understanding. For the past twelve months, he said, we have had our weather in "big chunks"—drought and burning sun, cold and damp, then more dryness and heat—the upshot of it all being that this season "takes the cake for eccentricity."

AS THE GARDEN is one of those papers which are honoured by being kept and bound, I have asked the Editor's permission for a considerable space to record all that I have been able to find out about the season of 1912. It is an historical one, and it must needs be passed down to posterity like "the hungry forties," to tell our spiritual children what their forefathers then passed through. My notes are mainly founded on my own personal observation; but it will be seen that in several cases I have drawn upon the experiences of others, communicated either verbally or by letter.

Its Earliness.—"Coming events cast their shadows before." I was very surprised at the time—but I am not now—to get a letter from the old veteran of Ard-Cairn, Cork, quite early in the year to say that he had cut a Daffodil bloom from the open on January 16, which, in his long experience, was a record. He evidently thought I might think it one of his Irish tales, so phenomenal was it, so he sent me the flower itself to preclude any possibility of doubt. I am sorry to say I have not kept a many years' list of openings myself, but I am able to give Alert. This year its date was March 6; last year it was March 25. Perhaps as striking an instance as any that I can mention is the experience of Mr. T. Batson of Beaworthy, North Devon. He is a keen hybridist, and he puts all manner of details in his pocket-book every season. This year he began to cross on March 12; in the six previous ones his earliest date was April 8. Lastly, we have the Midland Show. Never before has it been too late for Pearson. Hardly ever, if ever, has Milner been able to stage. And, speaking of myself, my late garden has given me this year the time of my life at Birmingham. Two factors seem to fully account for this extraordinary precocity: First, the unwonted early ripening of the bulbs in 1911; and, secondly, the mild spring of 1912, when not only had we warm days for weeks together, but also almost an entire absence of frost at night-time.

The Behaviour of the Plants.—As everyone anticipated, we suffered from our unwelcome visitors of the past year. The merodon, the Daffodil fly, was then very much in evidence,

visiting gardens where he had never been before, and certainly not neglecting his old haunts, in both cases leaving unpleasant reminders of his visits. So, too, was Mr. *Fusarium bulbigenum*, after a very long absence, enticed by the great warmth of the summer; he made one of his few and far between calls, and he, too, did not forget to let us know he had been. Bulb-growers suffered severely last autumn from both of these causes. Hundreds of Mme. de Graaff and *Horsfieldii* had to be thrown away. In my own case some imported *Barrii* conspicuus and some English-grown Mme. de Graaff were the special sufferers from the fungus, but I could see traces of it in the planted bulbs. Some newly-bought *Venus* and some home-grown *Jaune à Merveille* were the worst, but I traced it in a few other kinds—just odd bulbs. The Rev. T. Buncombe sent me foliage of one of his *Poets* which prematurely turned yellow and then went brown; and I had letters from Mr. W. F. M. Copeland, Mr. Ormston Pease and others telling of similar experiences. Quite lately I have been wondering if all this was not the result of *Fusarium*. The appearance of the foliage and the bulbs of my own *Jaune à Merveille* have suggested the idea. With regard to the merodon, it seemed to pick and choose its varieties. *Doris* was very bad here, and there were one or two others to which it paid too much attention. I have an idea that it goes most of all where the flowers are left on and not gathered. I must have many hundreds of thousands of bulbs, and each year every one is taken up and cleaned, so that it is fairly easy to detect the merodon. We possibly might find an odd one or two in an ordinary autumn, but it was different last time. This visitation was universal. Growers who had never had it before had it then, and all over Britain grub-containing bulbs must have been planted; and we see, or do not see, the results now in blanks or wretched leafage. Yellow stripe has been unusually prevalent. It has appeared in gardens which previously knew it not, and on varieties which heretofore were thought to be immune. I cannot say I expected it, but I ought to have done. Poor things! the cold, water-logged soil in which everywhere bulbs had to pass the winter and the early weeks of spring quite account for it. I for one do not think it is infectious. It is only a sign that they have to live in a soil or an atmosphere which they do not like. Environment affects bulbs as it does human beings. Another noticeable feature which occurred in practically more or less every variety was the non-bursting of the enveloping sheath of the leaves. It hung on till they were ever so high, and my men had to spend a very considerable time liberating them. The effect was distorted and brittle foliage, giving the plants an untidy look. I wonder what caused it—the membrane of the sheath being too strong or the leaves being weaker than usual. I am inclined to think it must have been the latter cause, for flower-stems were unusually floppy this year. Instead of holding themselves rigid and upright, many bore their flowers in a graceful curve, like the bells on springs which we fasten to our doors and shutters when nocturnal visitors are believed to be in the neighbourhood. A last feature to be mentioned is the abnormal splitting up of bulbs, especially in certain varieties that are addicted to it. When such things as *Lucifer* and *Seagull* were lifted last season, the increase was noticed to be quite abnormal. In some varieties it was not so obvious as in others, but when we came to the leaf period of the present year, both under glass and in the open, every now

and again we saw a great number of narrow, puny-looking leaves some clustering round a fairly normal plant, others all by themselves. What is the meaning of this? Is it a suggestion of Nature? I mean, is there any correlation between this and the usual behaviour of bulbs in the difference which a hotter and lighter and a cooler and heavier soil makes to their increase? Naturally, the flowers from the much-divided-up bulbs were either fewer in number (*Lucifer*) or smaller in size (*Seagull*).

JOSEPH JACOB.

(To be continued.)

NEW AND RARE PLANTS.

FIRST-CLASS CERTIFICATES.

Miltonia vexillaria Snowflake.—A pure snow white *Miltonia* with just a faint tint of yellow in the centre. The individual flowers were about four inches across, with an average of six to each spike. The plant in question carried thirteen spikes, and so admirably had it been grown that it was also awarded a cultural commendation. Shown by Lieutenant-Colonel Sir George Holford, K.C.V.O.

Elæocarpus reticulatus.—This is one of the most ornamental of a small yet beautiful genus of greenhouse flowering evergreen shrubs, and one that should prove of much value for the cool conservatory or like place. The small examples shown were 2 feet or so in height, bushy and freely branched, and flowering practically from base to summit. The branches extend in a sub-erect manner, and from their under sides depend graceful racemes of deeply-fringed flowers a third less in size than *Deutzia gracilis*, and borne with a freedom and profuseness akin to that well-known plant. The flowers are white, and have the hard, crisp touch of some of the Everlastings. This charming plant is not new, and is one of the many delightful subjects of which Messrs. Veitch appear to be the only present-day guardians. Not for a long time have we seen anything more distinctly beautiful than this pretty plant. Exhibited by Messrs. James Veitch and Sons, Limited, Chelsea.

AWARDS OF MERIT.

Delphinium Dusky Monarch.—The colour is violet purple; the individual flowers are large and with a dark centre; the spike very handsome and well formed. From Messrs. Kelway and Son, Langport.

Carnation Queen Mary.—This is the handsome and powerfully fragrant *Carnation* selected by Her Majesty the Queen at the time of the Coronation last year from a basket of seedling varieties grown and supplied by the raiser, Mr. Blick. In the matter of fragrance the variety is a revelation, and probably quite unique. It is a seedling, through several generations, of the highly-popular *Lady Hermione*, and, like it, a plant of great vigour and freedom. The colour is salmon rose.

Carnation Attraction.—A snow white variety of great purity of tone and splendid petal quality. This handsome variety has perfectly symmetrical flowers, and should figure well on the exhibition board. These two fine novelties were exhibited by Mr. C. Blick, Warren Nurseries, Hayes, Kent.

Silene Hookeri.—Quite recently this delightful Californian alpine has again come into prominence after an absence of years. The flowers are large, with deeply-lacerated petals, which are coloured rose and striated with white. The plant is very dwarf; the leaves, and indeed the whole plant, is

EDITORIAL NOTICES.

Every department of horticulture is represented in THE GARDEN, and the Editor invites readers to send in questions relating to matters upon which they wish expert advice.

The Editor welcomes photographs, articles and notes, but he will not be responsible for their safe return. All reasonable care, however, will be taken, and where stamps are enclosed, he will endeavour to return non-accepted contributions.

As regards photographs, if payment be desired, the Editor asks that the price required for reproduction be plainly stated. It must be distinctly understood that only the actual photographer or owner of the copyright will be treated with.

The Editor will not be responsible for the return of artistic or literary contributions which he may not be able to use, and the receipt of a proof must not be taken as evidence that an article is accepted. Publication in THE GARDEN will alone be recognised as acceptance.

Offices : 20, Twickenham Street, Covent Garden, W.C.

NOTES OF THE WEEK.

Holyrood Palace Gardens.—By command of the King, the gardens of the Royal Palace of Holyrood, Edinburgh, are again to be open to the public on the Mondays of the summer months. They were open on Monday, June 17, and this will be continued till the end of September, the hours being from two o'clock till five o'clock. The privilege has been largely taken advantage of in former years, and the gardens, which are under the care of Mr. Smith, are now looking well for the season.

A Good Early Pea.—A culinary Pea that has given a good deal of satisfaction this year is Carter's Eight Weeks. Sown in the open garden on February 15, and given only ordinary treatment, pods were ready for picking on June 5. A row 6 yards long has already yielded two pecks of well-filled pods, and at least another peck will be gathered before this note appears. The pods are of good size, and in nearly every instance are borne in pairs. The quality, too, is excellent, and we regard it as an early Pea of considerable merit and worthy of extended cultivation.

Variation in Sweet Peas.—Mr. Cuthbertson recently brought examples of Sweet Peas before the scientific committee of the Royal Horticultural Society which he thought showed reversion to original forms. In the white waved variety (Etta Dyke), in the waved cream variety (Dobbie's Cream), and in the pink and white bicolor (Mrs. Cuthbertson) he had found a deep purple-flowered plant—one in a thousand, perhaps—giving a colour approaching that of the wild Sweet Pea, but retaining the waved formation. Mr. Cuthbertson also showed Sweet Pea leaves with some of the tendrils becoming leafy, the result possibly of high cultivation.

Primula Unique.—This is a charming *Primula* derived from intercrossing the two well-known Chinese species *pulverulenta* and *cockburniana*. The cross has been made both ways, and there is scarcely any difference between the seedlings, excepting when *pulverulenta* was the mother plant; then an occasional seedling had slightly darker flowers. It is fairly intermediate in character, but it retains the perennial habit of *pulverulenta* and a certain amount of its vigour, while the orange colour of *cockburniana* is reproduced in no small measure. The result, so far as colour is concerned, is a pleasing rosy red, and quite distinct from any other hardy *Primula* in cultivation. A similar plant known as the Lissadell hybrid has been raised from the same parents. The best effect is produced when a batch of about a dozen plants are arranged together. A shady, moist spot should be chosen, but where it is not too wet during the winter months, for a great many *Primulas* die from this

cause. *P. Unique* was originally raised by Messrs. Veitch of Chelsea; but since then Messrs. Bees, Limited, and other firms have taken it up, and now strong examples can be bought for a small sum.

Sir Alexander Cross, Bart.—The honour that has recently been conferred upon Mr. Alexander Cross of Glasgow is received with gratification throughout the horticultural trade. The new baronet is the senior partner in Messrs. Alexander Cross and Sons, the well-known chemical manufacturers, who have placed on the market insecticides of great horticultural value. Apart from a successful business career, Sir Alexander gained prominence as a politician, representing the Camlachie Division of Glasgow for eighteen years, retiring in 1910.

Lieutenant-Colonel Sir David Prain.—The announcement of the honour of knighthood recently conferred upon Lieutenant-Colonel D. Prain, F.R.S., will be received with feelings of the greatest pleasure by his many friends both at home and abroad. Sir David Prain is an ardent botanist and horticulturist. He was formerly Superintendent of the Calcutta Botanic Gardens and Director of the Botanical Survey of India. His publications of the botany of India are numerous and critical. Since 1905 he has been Director of the Royal Botanic Gardens, Kew.

A Rare Calceolaria.—There is flowering in the Temperate House at Kew a remarkably distinct and rare Chilean species named *Calceolaria cana*. When not in flower the growth and appearance of the plant are suggestive of a *Stachys* rather than of a *Calceolaria*, for it is only some three inches in height, with short, white, densely woolly leaves. The flowers are borne on slender scapes 1 foot to 15 inches in height. The colour of the small blossoms is pale purple or rose on a white ground, with darker purple blotches and yellow markings in the throat. A feature of *Calceolaria cana* is the delicious Violet fragrance of the blossoms.

Dipteronia sinensis.—This is a deciduous bush or small tree recently introduced from Central China by Mr. E. H. Wilson. *Dipteronia* is a monotypic genus nearly allied to the Acer or Maple family. A bush some eight feet in height is at present flowering for the first time near the Refreshment Pavilion at Kew. The small greenish white flowers are freely borne on pyramidal panicles. These, however, are of no decorative value, the beauty of the plant for garden purposes being the highly-ornamental foliage. The largest of the pinnate leaves exceed a foot in length, and are about four inches to five inches wide. The leaflets are usually eleven or thirteen in number on mature specimens. Cuttings root freely made of half-matured growths in July and August, while layering also forms a ready means of propagation.

CORRESPONDENCE.

(The Editor is not responsible for the opinions expressed by correspondents.)

Choisya ternata.—With regard to the correspondence at present going on in THE GARDEN re the hardness or otherwise of *Choisya ternata* in different parts of the United Kingdom, I beg to say that in one of our shrubberies here it has been planted for more than ten years and has never been injured even with 26° of frost, while *Olearia Haastii* has been killed to the ground. I may say that neither has had any protection. — JAMES HARVEY, *Mortonhall Gardens, Liberton, Midlothian.*

A New and Noteworthy Rose.—Of all the new Roses of recent introduction, may I claim the privilege of stating *Sunburst* to be one of the most beautiful? It is a good grower, of rather dwarf habit, but carrying its blooms on substantial purple stems; the foliage as described in Messrs. Pernet-Ducher's catalogue is lovely; also the coloured illustration in the same of the blooms is "most truthful," but not quite up to the transparency of the orange and cadmium. I have just cut a lovely specimen from a plant growing in the open, and can only say I leave the popularity of this beautiful variety of Hybrid Tea to the admirer of the elegant, strong and free-blooming Rose. — CHARLES W. CROSEY, *Dorking.*

Lapagerias in the Open Air.—These plants are beautiful greenhouse climbers, and specially adapted for growing in houses with north, north-east, or north-west aspects and in positions where their wiry branches can be trained to wires under the roof glass or immediately over a path. A number of years ago, a gardener of my acquaintance planted several in a cosy corner facing the south in the open air, and trained the shoots to the walls of the mansion. The plants survived three ordinary winters without any protection and flowered the third year. I have not heard anything about them since, and would like to learn whether any of your numerous readers or contributors have had any experience with these plants as wall climbers outside. I am of the opinion that in southern counties, and with light winter protection, *Lapageria rosea* and *L. alba* may be so grown.—B. [Quite recently we noticed *Lapageria rosea* growing with remarkable freedom in the open in Mr. J. C. Eno's garden at Wood Hall, Dulwich. There is no doubt that this beautiful climber is much harder than is generally supposed.—ED.]

Rhododendrons.—On page 297, issue June 8, "Spartan" has some very interesting remarks relative to the soil suitable for the growth of these plants. I have had to deal with the cultivation of many *Rhododendrons* covering acres of ground both in northern and southern counties—chiefly in the latter—and have found them thrive well in various kinds of loam. I do not believe in putting much peat around the roots; in very dry summers the whole mass gets extremely dry, and then the lower leaves on the stems fall off in showers. Some of the best specimens I have seen were grown in sand, shingle and poor loam, with a very small amount of peat. Annual surface mulches did a lot of good in this case. In one garden in Lancashire there was a natural rockery, and *Rhododendrons* grew well among the rocks, their roots entering the crevices and permeating the thin crust of soil on the surface. The plants certainly do not like lime nor very strong clay.

They live even in the latter, but do not carry many old leaves. All soils should be deeply trenched for the plants, although they are mostly surface-rooting. Rotted cow-manure, one-half, and rough fibrous loam, one-half, form the best compost for annual top-dressings.—G. G.

A Useful Speedwell.—Under this heading you have a paragraph in your issue of February 10, in which you speak of *Veronica cupressoides* as a low-growing shrub. This is an error, but is one which is shared by many nurserymen, as is evidenced by their catalogues. The paragraph states that "it is probably as frequently met with as *V. salicornioides* as under its correct name, but there can be no doubt of the proper one." I quite agree with the last statement, but the correct name is *V. salicornioides*. Cheesman, in the "Manual of the New Zealand Flora," describes *V. cupressoides* as "a much and closely-branched,

LIEUTENANT-COLONEL SIR DAVID PRAIN, F.R.S.,
DIRECTOR OF THE ROYAL BOTANIC GARDENS, KEW.
(See preceding page.)

round-topped shrub 3—6 feet high." *V. salicornioides* he describes as "a small, much-branched shrub 1—3 feet high." I have both shrubs in my garden, and know them well. The appearance is somewhat similar, but *V. cupressoides* is a deeper shade of green, lacking the yellowish tinge which is present in *V. salicornioides*. Strange to say, I have never seen a well-grown specimen, of *V. cupressoides* in cultivation, as when planted near other shrubs they become leggy, but I have seen them growing in the shingly bed of some mountain stream, of perfect shape, forming round, green mounds suggestive of haystacks, as neat and regular as though they had been trimmed with a gardener's shears. From the localities in which it grew naturally, *V. cupressoides* should be hardy in England; but I would advise anyone growing it to plant it on a lawn or somewhere away from other shrubs or strong-growing plants, so that it could assume its beautiful natural shape. I had noticed the error some time ago, which your paragraph

authoritatively confirmed; hence these lines—
A. BATHGATE, *Dunedin, N.Z.*

The Naming of Roses.—I quite agree with Mr. Easlea in his protest against our American cousins re-naming well-known Roses, and also that the practice should be condemned by all responsible Rose-lovers. I know well the confusion that arose when Mrs. W. J. Grant was re-christened *Belle Siebrecht*, but in this case the Rose was purchased and disseminated by Messrs. Siebrecht and Wadly, and, of course, they had the right of re-naming it. But in the case of old-established favourites, such as *Antoine Rivoire* to be named Mrs. Taft seems to me to be carrying the thing too far. I can remember a Rose being sent out in America some years ago named *American Banner*. Supposing we over here had copied our American cousins and called it *Union Jack*, why, there would have been quite an uproar. I wonder what our genial friend, Mr. E. G. Hill, would have said if we had re-named his beautiful seedling Mrs. Theodore Roosevelt and called it, say, Mrs. John Burns. I hope that, as THE GARDEN has a wide circulation in America, a friendly protest from a Rose-lover on this side may have some practical result in putting a stop to such re-naming alluded to. We do not mind how many good Roses Americans raise and name, especially if of the quality of *Richmond*, *Reliance* and *Radiance*; but please, Brother Jonathan, do not claim the right to re-christen British, French or German novelties.—
ROSARIAN.

Curious Laburnums.—There are at present in the gardens of Lees, Coldstream, two unusual specimens of *Laburnum* which were purchased abroad some twelve years ago. The shrubs are about eighteen feet to twenty feet high, and are profusely decorated with long pendulous sprays, similar to ordinary *Laburnum*, of a pale shrimp pink colour. But mingled with these, at quite capricious intervals, the ordinary yellow blossom is seen, sometimes in single sprays, occasionally appearing as two or three yellow flowers on a pink spray, and on two occasions a single bloom has been found, half of which is pink, the other half being yellow; while more remarkable still, occasional bunches are seen totally different in every respect to the other two. They are exactly the colour of the ordinary *Wistaria*, but grow in a dissimilar manner to either *Wistaria* or *Laburnum*. At the end of a year or two these bunches appear to die off (several of those previously noticed having done so), but on other parts of the trees they have made their appearance, though never so numerous or vigorous as at present.—X. [The *Laburnum* referred to is a fairly well-known kind, and is correctly named *L. Adamii*. A graft hybrid between *Laburnum vulgare* and *Cytisus purpureus*, it was raised upwards of half a century ago by a French nurseryman near Paris. The habit has been practised for many years of grafting *Cytisus purpureus* upon stocks of *Laburnum vulgare*, and in one instance the peculiarity of purple and yellow *Laburnum* blossoms and tufts of *Cytisus purpureus* occurred as a freak on the grafted stem. This freak, known to scientists as a graft hybrid, was perpetuated by grafting, and was the original parent of all the trees bearing the three kinds of flowers which are now to be found. An illustrated article on graft hybrids between the *Medlar* and *Hawthorn* appeared in THE GARDEN for July 1, 1911, such hybrids are not common, although there are several well-authenticated instances. There are several fine examples of *L. Adamii* in the gardens of Syon House, Brentford.—ED.]

Rose Tea Rambler.—This fine old Rose, sent out by Paul and Son in 1903, is flowering with more than usual freedom this season, and presents at the time of writing a picture of most refined beauty, the richly-coloured salmon pink flowers having their beauty accentuated by the bronze green tinted foliage. It is an ideal climbing garden Rose, valuable alike for pergola, archway or wall. The growth is rampant, and strong canes frequently measure 8 feet to 10 feet, many of which spring directly from the base of the plant, so that little difficulty is ever experienced in keeping the plant in full vigour, and when well furnished with wood of this character, the resulting floral display is invariably great. Rose Tea Rambler belongs to the Polyantha group of climbing Roses, the flowers being borne in large clusters, and, being thinly disposed, the effect when in flower is light and graceful. It flowers during the end of May and early June, and again sparingly in autumn.—T. S.

Rosa gigantea.—Of the many attractions at Kew during the past month, one which was of special interest to a large number of visitors was the flowering of this giant Rose, as only on very rare occasions has it flowered in this country. This species was introduced from Upper Burmah by Sir Henry Collett in 1889, and ever since its introduction plants have been cultivated at Kew under various conditions; but it was not until the spring of 1910 that it flowered, when the plant in the Himalayan House produced four flowers. Again, in 1911 eight flowers opened. This spring, however, the plant flowered profusely. This, no doubt, may be attributed to the hot summer experienced last year, which enabled the wood to become thoroughly ripened. Planted out in a border and trained to one of the rafters of the house, the plant has attained a height of 45 feet, while the stem is about five inches in diameter at the base. The flowers are from 4 inches to 5 inches in diameter, of a deep buff colour in the bud stage, changing to pure white as the flower expands; the stamens are bright yellow. This Rose should not be pruned hard back, but merely have the strong, soft shoots cut out, leaving the more twiggy growths, as it is on these that the flowers are produced. *R. gigantea* is a vigorous grower, and in its native habitat grows to the top of the large forest trees, often reaching a height of 60 feet to 80 feet. Although regarded as tender, I believe this Rose would thrive in such places as South-West Cornwall and the South of Ireland.—W. T.

Exhibiting Daffodils.—I was interested to see the letter from Miss Currey in *THE GARDEN*, page 250. I have always admired Miss Currey's tastefully-arranged exhibits of Daffodils, fine flowers shown with long stems, looking as fresh as the proverbial Daisies, in spite of the long railway journey and the trip across the Irish Channel; but when she pleads for the paper collar as a harmless device and a panacea for sea-sickness and all the troubles of a prolonged railway journey, I hope we are not to conclude that she wishes us to believe that without the collars her flowers could not be shown in good condition, say, at the Vincent Square Hall; I should be sorry to think so! If several flowers of the same variety can be packed together without the need for paper collars, then surely the solitary bloom of the precious seedling can just as well travel among them as if it had been one of that variety; but my point is that these collars are used not so much to protect the flowers from injury in transit as to prevent the natural tendency of the perianth segments, in some varieties, from "reflexing." "Irritation" is not a strong enough

word to express my feelings in the matter. I have only too often seen flowers shown with these collars left on, because, if they had been taken off, the perianth segments would have reflexed so badly as to make the flower fit only for the rubbish-heap. At one of the leading shows this season I saw a flower which at once attracted my attention; it was "apparently" faultless in shape and had a perianth as flat and as round as a penny, suffused with a shade of colour I had never seen in a Narcissus perianth before—a delicate suspicion of apricot pink. I gazed in wonderment on this marvellous flower; so extraordinarily wonderful was it that my suspicions were aroused, and I took a peep behind the scenes to see how it was done. I found, as I expected, a neat, very neat, little disc of cardboard carefully placed up against the back of the perianth. This card was of just the correct depth of colour to show through the white perianth, and I can assure Miss Currey that this card served the double purpose of lending its colour to the

THE ROSE GARDEN.

THE PROSPECTS OF THE ROSE SEASON.

WITH many readers, by the time these lines are in print the Rose season will be almost in full blow; but I am aware *THE GARDEN* is widely circulated, and growers in the North have reason to rejoice that they live in those parts, especially if they are exhibitors. It is a remarkable year, one of which few can recall the equal. To see such a glare of blooms out the first week in June is to recall the times when one depended solely upon the old Gallicas and Hybrid Chinese. Most of us have received some very welcome showers, and now the buds will fill up well.

Amateurs from the Home Counties who depend solely on cut-backs will be sadly out

A FLOWERING SPRAY OF THE GIANT ROSE (MUCH REDUCED). IN ITS NATIVE HABITAT THIS ROSE GROWS TO A HEIGHT OF 60 FEET TO 80 FEET.

flower and supporting a refractory petal, which, directly it was removed, sprang back flat against the stem, leaving a very ugly hole in the side of the flower, and the imposture was revealed. If the Royal Horticultural Society or the Midland Daffodil Society would say that there was to be no more faking and no more paper collars, we might trust exhibitors in the same way that we trust them when we say that they are to show only flowers that they have grown themselves.—W. A. WATTS.

FORTHCOMING EVENTS.

June 25.—Royal Scottish Arboricultural Society's Excursion to Deeside (five days).

June 26.—Colchester Rose Show. National Rose Society's Show at Southampton. Richmond Flower Show. Royal Botanic Society's Meeting.

June 27.—Isle of Wight Rose Show at Ryde.

June 28.—Canterbury Rose Show. National Rose Society's Show. Hertford Horticultural Show.

June 29.—Windsor Rose Show. Reigate Rose Show. Bradford Paxton Society's Meeting.

of it at the "National" on July 9, unless they were able to foretell the weather we have had and pinched out the first buds of the earliest kinds. I should say that the Southampton Show on June 26, and also Richmond and Colchester on the same date, will bring out remarkably good displays. We are now having the proverbial dripping June, and I should say we are likely to see the rich-coloured Roses in grand form. It may even be a year specially good for some of the older Hybrid Perpetuals, for I have seldom seen them looking better, and many of the semi-double kinds are coming out magnificently in the cooler, moist weather now prevailing.

Even the maiden plants are coming into bloom here in Essex, so that with another month before the greatest show of the year it is to be feared many will find the date too late for them, and I think it a very wise provision of the National Rose Society to establish a show like that at Southampton; only I wish it had been in London instead.

Those growers who were well ahead in providing stimulants will be rewarded now that the rains have come; but even now we can do much to help the buds by dusting the ground with a good artificial manure and hoeing it in. A season like this has demonstrated the error of depending solely upon liquid manure, for how can one water all one's Roses as they require it; whereas in a rainy season we can apply artificials and allow the rain to do the watering for us. I am a believer in putting the food into the land in the autumn, so that the winter and spring rains can carry it down for use by the roots when required.

I have had an object-lesson this season in what may be accomplished by very moderate pruning. Last season some hundreds of Roses in a garden close by were hard pruned. This year a new gardener arrived who believes in only moderate pruning, and there is, indeed, a glorious array of bloom. As I explained to the owner, this practice might do well in alternate years, but I would not advocate it annually, or we should find that basal growth would be very meagre. Again, the retaining of the early growths is somewhat risky, because far too frequently we have late frosts that spoil all our prospects. This year there was practically nothing to do any serious harm. The Roses I allude to are growing in specially-prepared beds, made two years ago. The soil was very light, made up chiefly of old turf, leaf-soil and rubbish from the soil-yard. A cesspool close by is cleaned out occasionally and pumped straight on to these beds, the result being growth I have never seen equalled. Many exhibitors who have a goodly number of the staying Roses, like Queen of Spain and Bessie Brown, will be very glad indeed, and I imagine it will be such Roses that will be very much to the front on July 9.

Although aphid has wrought havoc to neglected Roses, those who have sprayed early and continually have been able to keep their Roses in good trim. So far, black spot has not been very much about, which is something to rejoice over, because this pest is most annoying.

The need of a public Rose garden becomes more manifest every year. Our collection is now so prodigious that it is only by some such garden, where visitors could see for themselves the various Roses growing, that they are likely to satisfy themselves. Such a public Rose garden as that at Westcliff-on-Sea is a great boon and is worth a long journey to see, and I am glad to know it has been brought well up to date with the latest novelties.

Few new Roses have pleased me more than Reliance, Mr. E. G. Hill's fine seedling. It is like a huge White Lady, with very large guard petals and warm shell pink colouring inside and yellow shadings; in fact, it seems to be a blending of

White Lady, Mildred Grant and Melanie Souper. It must surely take a great position as a show flower.

The wichuraiana Roses are now coming on fine and promise to be very effective this year. So also are the lovely little Polyanthas, and altogether, although an early one, the Rose season of 1912 will be one long to be remembered.

ROSE MARQUISE DE SINETY (H.T.).

[See coloured cover.]

This is without a doubt one of the grandest colours yet produced, and it is certain to remain a great favourite for many years to come, although there are rumours of rivals. An idea has got abroad that Marquise de Sinety is a poor grower, but this I am

fruit fragrance. I do not advise it to be grown as a standard, although it will grow in that form, but it is not so adapted to making a good head as other Hybrid Teas, such as Mme. Ravary. P.

[Our coloured cover was prepared from flowers kindly supplied by Messrs. Merryweather and Sons, Southwell, Notts.—Ed.]

THE FLOWER GARDEN.

A KASHMIR POPPYWORT.

(*MECONOPSIS SINUATA LATIFOLIA*.)

For sheltered and shady corners, either in the rock garden or border, there is no more charming plant than the *Meconopsis*, of which there are several kinds well worth growing. For shady banks among Ferns, our native species, *M. cambrica*, is a most effective plant with its wealth of yellow flowers. In such positions it may be naturalised, and self-sown seedlings usually appear in abundance. Of all the members of this beautiful family it is the best, if not the only, perennial, all the others usually dying after they have flowered. The headquarters of this family is in the Himalayas, whence they extend along the mountain ranges into China. North America is represented in the genus by one species, which is found in California, an annual with beautiful brick red flowers. The most handsome member is the *Satir-Poppywort* (*M. Wallichii*), which is well known in gardens with its 5-foot or 6-foot stems, covered on the lower portion with beautifully-cut leaves, and producing for the greater part of its length its branches of purplish blue flowers.

M. sinuata latifolia was introduced in 1906, seeds having been sent from Kashmir in the spring of that year. From a rosette of stalked, somewhat oblong leaves, with sinuate margins, arises the 2-foot stem, covered, like the leaves, with stiff, prickly hairs. When about a foot high the terminal flower, of a pale blue colour, opens, disclosing a bunch of orange-coloured stamens, in the centre of which is the ovary and purple style. After this the stem continues to elongate, and produces a succession of its beautiful flowers

on pendent stalks during the months of May and June.

A suitable companion to the above, of a similar habit, but with thinner and more deeply-lobed leaves and darker blue flowers, is *M. aculeata*. It also differs in having a rounder and shorter capsule. Another charming plant is *M. racemosa*, with long, narrow, entire leaves and deep blue flowers.

All the above plants may be successfully grown in a cool, shady place, planted in well-drained soil composed of loam with plenty of leaf-soil, as well

THE BEAUTIFUL POPPYWORT (*MECONOPSIS SINUATA LATIFOLIA*)
NATIVE OF KASHMIR.

glad to disprove, for it grows with me in heavy clay soil quite equal in vigour to Mme. Ravary, both on the hard-pruned plan. I have now growths of Marquise de Sinety fully 15 inches in length bearing grand buds, which, when they begin to show colour, are a carmine ochre colour, but as they expand they are a superb Roman ochre, shaded with bright rosy scarlet. The foliage is a most delightful reddish shade, very leathery and glossy, and of enormous size; indeed, the beauty of the foliage of this variety is only equalled by Joseph Hill. There is also a delicious ripe

as some peat to make it lighter and more spongy. Seeds must be fresh, and should be sown in pots in a cold frame or in a house with a little heat. The seedlings must be pricked off into pots or boxes as soon as they are large enough to handle. If pricked off into boxes first it will be advisable to pot them off later, as they are better planted out of pots into their permanent positions. W. I.

SWEET PEA NOTES.

Fresh Mulching.—It is not always either necessary or convenient to put down fresh mulching to the Sweet Peas; but in view of the dry weather of April and the early days of May, when artificial watering had to be done, an endeavour ought to be made to strain a point in its favour this year. For purposes of keeping the soil cool and preventing the waste of food, the old material is quite useful, provided that it is kept open and sweet by constant loosening, but it is not now giving much food. If, therefore, there is some good, rotten manure at command, spread a nice thickness after the worn-out stuff has been raked off. There can be no doubt that the plants will derive marked benefit from it in many ways before they have done blooming.

Variety in Food.—Feeding the plants will be under the most serious consideration now, and no efforts ought to be spared to afford variety. The constant application of one food to a human being does not produce the finest man or woman, for the simple reason that the body becomes satiated of the one thing given incessantly, and plants are sure to come into a somewhat similar, if not identical, state. To achieve the best reward, at least three kinds should be at disposal, and these may advantageously be applied alternately. However, it is obvious that this detail of management must be subject to the conveniences of each cultivator, who may be relied upon to do the best in his power for his plants. It is of the utmost importance that, no matter what form the feeding may take, it shall never be used when the soil is dry and never be applied strong.

Thrips.—Fortunately for the peace of mind of the majority of Sweet Pea lovers, this pest does not invariably attack the plants, because they would find in it a persistent enemy, which is by no means easy completely to exterminate when once it has made itself at home. Although it is not an occupant or visitor to every garden, the grower should ever be on the look-out for it, so that the instant one is seen it can be destroyed. It will be found to attack, and very quickly cripple, the growing points of the shoots unless it is destroyed. The application of an approved insecticide, exercising the utmost discretion that it is not used in a strong state, is permissible, but vigorous hosing and hunting will suffice if steps are taken early enough.

Disbudding.—This will continue to have the most intelligent attention, as well as regards lateral growths as blooms. The severest form of bud suppression as adopted by those who are

growing for exhibition is neither necessary nor desirable in general culture, and each cultivator must proceed on the lines that he knows will best suit his particular objects and requirements. As a rule, it is not desired to have the plants in full bloom much before the middle of July, but the dates of fixtures must be closely watched and blossom buds all removed a definite number of days before them to secure superior quality. The time will depend on the situation of the garden and the season.

Evening Hosing.—When the day has been burning with the beat of the sun, and the atmosphere has become perfectly arid, evening hosing or syringing, according to circumstances and conveniences, must have consideration. It is seldom that real harm can be done, but obviously the incessant pouring of cold water upon the soil will reduce the temperature of the ground, and thus

GARDENS OF TO-DAY.

MR. E. A. BOWLES' AT WALTHAM CROSS.

MR. E. A. BOWLES of Myddelton House, Waltham Cross, is so well known among horticulturists that no apology is needed for bringing his charming old-world garden before the notice of our readers. It was on a sunny day in early May that we responded to Mr. Bowles' invitation to spend the day with him, a day when the sun was gleaming hot and the Tulips and Magnolias were scattering their petals over the garden with a lavish haste, as though racing to keep pace with an exceptionally early summer.

We have, long ago, learned that a garden is a reliable index to the tastes and dispositions of its owner; hence, just as Mr. Bowles is a man of

A CHARMING DISPLAY OF IRIS GERMANICA BY THE WATERSIDE IN MR. BOWLES' GARDEN AT MYDDELTON HOUSE, WALTHAM CROSS.

afford a check to the action of the roots; it may also so batter down the mulching material as to render it impenetrable by water and air, and the health of the plants must inevitably suffer. It is therefore apparent that intelligence will have to be exercised in the matter if handsome benefits are to accrue. Wisely-applied water is good; if unwisely applied it is the reverse.

Green Fly.—As far as insect enemies are concerned, this is indisputably the worst with which the Sweet Pea lover has to contend; and it is quite enough to satisfy the majority in its particular direction. It is a visitor that wastes no time in making itself perfectly at home and multiplying at a rate that is enormous, and the man who would always keep the upper hand must strike early and strike hard, repeating his attacks as necessity demands. Hosing and syringing are excellent.

HORACE J. WRIGHT.

many parts, so is his garden made up of many sections. For you must know that the owner of this garden is a keen entomologist, an ardent traveller and plant-collector, an artist of no mean order, a scientist, an expert on rock plants, a keen Daffodil enthusiast, an authority on the Crocus ("The Crocus King" the late Mr. Gumbleton used to call him), a Master of Arts, a strenuous worker in the cause of horticulture, and, above all, a good amateur gardener in the truest sense of the word. Thus in his garden a raven keeps company with tame gulls, moorhens with ancient carp, entomological curiosities with the choicest plants; yet all seem to form one harmonious whole, just as the many outlets for his energy and skill combine to make a genial and greatly-esteemed man of its owner.

To deal with all that we saw of interest in the way of plants in this garden would occupy the whole

of this issue: but there were a few outstanding features that appealed strongly to us. Thus in one portion, with a flagstone pathway beneath a pergola designed for the purpose of showing plants to the best advantage, we found a number of plants of considerable rarity. There, for instance, were three of the Citrange, a cross between *Egle sepiaria* and an edible Orange. Bearing unmistakable evidence of the first-named parent, it is hoped that these will prove as hardy as it and possess the beauty of the Orange.

Here, too, was *Feijoa sellowiana*, in the open, a sturdy plant that was quite at home. How the late Mr. Gumbleton used to rave over this shrub, which he grew so well in his Irish garden! Hard by, and overhanging a garden seat, was a splendid bush, some twelve feet high, of *Solanum crispum* Glasnevin variety, its bounteous display of lilac blue flowers being exceptionally pretty on this May day.

Seedling *Eucalypti* in multitudes, *Clematis montana* lilacina scrambling over the summer-house, with its pretty pale lilac flowers, with

company with the Yews referred to by the water-side is a fine example of the Judas Tree (*Cercis Siliquastrum*), which has deeper-coloured, rosy red flowers than we ever remember seeing before. Apparently it is a variable species under different conditions.

Not far away from the water-side we come upon yet another section of the garden, and a most interesting one to boot. This is devoted to plant curios of all kinds, and the owner has certainly gathered together a wonderful array. Not only are they curious, but to the scientific mind many are of considerable interest. Here, for instance, is a "Witches' Broom" that was taken some years ago from an old Elder and started in life as a separate plant. It still retains the dwarf, herbaceous character that it possessed when attached to its parent, thus proving that the disruption of the plant-cells that took place at the outset was permanent. An Oak-leaved Laburnum and one with crinkled flowers, curious Daisies and Plantains, an Elm with twisted stem and foliage, as well as

ANEMONE SYLVESTRIS GRANDIFLORA GROWING AMONG ROCKS IN THE GARDENS AT MYDDELTON HOUSE.

golden-leaved Balm, and a gorgeous, golden-leaved Bramble that originated, we believe, in Canon Ellacombe's garden, were all to be found in this one little section of the gardens at Waltham Cross. Near by, and standing beside an old-world pond, was a fine specimen of the new *Viburnum rhytidophyllum*, with its long, leathery leaves and huge corymbs of creamy white flowers.

Flowing through the estate at Myddelton House and right through the gardens is the artificial river of the New River Company, and a portion of this, bordered with white and other German Irises, is seen in one of the accompanying illustrations. It is an effective grouping of these plants, which have been in this situation for a number of years. Flanking the river are some fine old Yew trees which must be many hundreds of years old, and on the lawn is a magnificent specimen of *Cedrus atlantica* that was planted by Mr. Bowles' great-grandfather just one hundred years ago. Keeping

hosts of other interesting plants, find a home here. Near by, on one side of a lawn, is a fine standard plant of *Wistaria multijuga*, with pendulous racemes 3 feet long of pale lilac flowers; an ideal way to grow this charming native of Japan.

Yet another section of the gardens Mr. Bowles has devoted to experiments with grey-foliaged plants and purple flowers, and the latter, at the time of our visit, were most interesting on account of the beautiful Darwin Tulips that were blooming. These, Mr. Bowles informed us, were selected for the purpose by our esteemed contributor, the Rev. J. Jacob. After much earnest meditation on the part of that gentleman, he advised, first of all, one named The Bishop, just as a dutiful parson should do, and in this case The Bishop has certainly justified its recommendation. It is the most lovely purple Tulip we have ever seen, and if money will buy them, some bulbs will find a home in our garden this autumn. It is of pale purple shade, tall

and sturdy. Faust is deep black purple; Duke of Westminster, very large, deep purple with white eye; Grand Monarque, very good deep purple; and Gruze is a magnificent Tulip of glowing hue, a little deeper shade than The Bishop. Those who want to plant purple Tulips this autumn may rely on all of these. We must ask Mr. Jacob to write some articles at planting-time, giving some good selections of Tulips according to their colours. Near by we noticed groups of a little *Viola* that seems to crop up everywhere in the gardens, and which we find is named, among those who know it, Bowles' Black. It is a really charming little Pansy, almost black in colour, with small yellow eye, and a very pert pose indeed. Eremuri are great favourites with Mr. Bowles, but this year the frosts and drought of late spring created havoc among them, so that they were not up to their usual standard.

The rock garden, which is reached by the foot-bridge shown in one of the illustrations, is one of Mr. Bowles' pet hobbies, and is of very great interest indeed. He has filled it with all the choicest plants obtainable; but, unfortunately, lack of space will not allow us to enter into details of these. We must, however, mention the beautiful cluster of *Anemone sylvestris grandiflora*, shown in the illustration on this page; *Berberis Fremontia*, with its blue foliage and crimson young shoots; as well as a number of beautiful blue seedlings of *Camassia Leichtlinii*. Indeed, one of the greatest charms of the whole of these gardens to us, and also to the owner and his numerous gardening friends, are the many kinds of seedlings of all genera that are constantly cropping up. The variations that Mr. Bowles finds among these are alone well worth allowing the self-sown seedlings to grow, although it is scarcely necessary to add that they need thinning with a ruthless hand when their merits or otherwise are determined. Such, then, is this garden of many parts; an old-world garden so near to and yet so far from London, where Mr. Bowles' Huguenot ancestors centuries ago settled and founded their home.

THE FRUIT GARDEN.

FRUIT TREES AND RED SPIDER.

THE branches of fruit trees trained on walls, either nailed or fastened to wires, are warmer and drier than those growing in the open border, throughout the summer months. The leaves on the wall trees very rarely get soaked and well washed with the rains like those in the open quarters, so that the general conditions are highly favourable to the spread of red spider. Of course, it is advisable to syringe the foliage of wall trees frequently and so cleanse them; but it is a very difficult matter to keep down red spider in dry, hot spells of weather by this alone. Soot, judiciously used, is a good preventive; a small quantity in a fresh state should be scattered on the soil at the foot of the wall. When moistened, the ammonia arising from it renders it very distasteful to red spider, which cannot thrive on the leaves immediately above it. Gently water the soot with a fine-rosed watering-can every two days or so in the absence of rain, and renew the soot every ten days. I have used it under Peach, Nectarine, Apricot and Pear trees with great success, the leaves of the trees being much larger and of a deeper colour than those on trees not so treated. SHAMROCK.

TREES AND SHRUBS.

RHODODENDRON KEWENSE.

THE accompanying illustration directs attention to a large-growing, showy *Rhododendron* which originated at Kew thirty years or more ago. Growing to a height of 10 feet or 12 feet, it is of vigorous habit and bears large oblong leaves after the manner of *R. griffithianum*. The flowers are borne in May, several appearing together in loose clusters about the time that the young growths appear. They are large, very fragrant, and white suffused with rose in colour, one variety having rose-coloured blooms. The young shoots are protected with good-sized rose-coloured bracts, which add to the effect of the plant at flowering-time. Unfortunately, no record was kept of the species used at the time the cross was made, and although the parentage has since been suggested to be *R. griffithianum* (*R. Aucklandii*) × *R. Hookeri*, there would appear to be some doubt about the matter, for both of those species have scentless or almost scentless flowers, whereas the fragrant blossoms of *R. kewense* are one of its chief attractions. It would appear that the fragrant *R. Fortunei* might more readily be one of the parents, for it is hardier than either *griffithianum* or *Hookeri*, and stands well out of doors in the neighbourhood of London, *kewense* doing the same, whereas *griffithianum* cannot be depended on, and it is doubtful whether *Hookeri* would stand, could it be obtained to make the trial. As *R. kewense* blooms and begins to grow rather early, it is advisable to give it a position sheltered from the early morning sun, so that in the event of a frost occurring in May its harmful effects may be minimised. By the introduction of a series of first hybrids, such as *kewense*, *Luscombeii*, *Manglesii*, &c., among the better-known garden varieties, the *Rhododendron* garden may be made of more general interest, while no more trouble will be added to cultivation and upkeep. Although *R. kewense* was raised over a quarter of a century ago, it still remains one of the most beautiful *Rhododendrons* in cultivation.

THE VIRGINIAN SNOW-FLOWER.

(*CHIONANTHUS VIRGINICA*.)

THIS is an interesting subject now flowering with wonderful freedom. The Virginian Snow-flower, or Fringe Tree as it is commonly called, is by no means a new addition to gardens, though it is not commonly met with; it was introduced at the latter end of the eighteenth century. It does well as a bush against a low wall, also as a small tree in the open shrubberies, and appears hardy enough

in both positions. It belongs to the deciduous section of our flowering shrubs, the leaves being lanceolate, glabrous and opposite, the petioles being much darker in colour than the leaves or other part of the stem. The flowers are produced in racemes fully 6 inches long, and cannot fail to be recognised.

Each flower has four strap-shaped petals fully an inch long and exceptionally narrow, purest white in colour when fully open, each blossom being borne on a fine stalk. This shrub, a native of North America, must not be confused

RHODODENDRON KEWENSE, ONE OF THE MOST BEAUTIFUL HYBRIDS YET RAISED.

with *Chimonanthus*, so nearly spelt alike, but, of course, totally distinct.

A NEW HONEYSUCKLE.

(*LONICERA THIBETICA*.)

THIS shrubby Honeysuckle was introduced, among others, by Mr. E. H. Wilson, and has this spring flowered with us for the first time. Apparently an excellent doer and perfectly hardy, it has developed into quite a large bush with long pendulous growths. The flowers, which are produced on the young growths, are of a pleasing lilac shade of colour and deliciously fragrant, mostly produced in pairs on a short, thick footstalk, but occasionally with a much smaller and later flower closely set between them. The flowers are about half an inch in diameter, quite tubular, and remain in good

condition for a considerable length of time on the plant. The growths are long, drooping in habit, and deciduous. The leaves are small, and the reverse is covered with a pale tomentum. Generally, these are produced in whorls of three on very short petioles, but occasionally one finds a branch with four at each interval.

A HANDSOME CLIMBER.

(*LONICERA CILIOSA*.)

THIS is one of the most handsome plants we have just at present, occupying a pole in the shrubberies, which it clothes perfectly with its twining growths, and is now covered with its trusses of deep orange yellow tubular flowers, which remain in a fresh condition for quite a long time. The plant, I suppose, derives its name from the leaves being ciliate, *i.e.*, the margin surrounded with fine hairs.

Elstree.

E. BECKETT.

A LITTLE-KNOWN DAISY BUSH.

(*OLEARIA MYRSINOIDES*.)

THE genus *Olearia* comprises a large number of handsome ever-green shrubs, all of which inhabit Australia and New Zealand, where they are commonly known as Daisy Bushes. While the majority of the species thrive and flower freely in the open air in the warmer parts of the British Isles, there are not more than three which can justly be classed as hardy in the London district. Of these the well-known *O. Haastii* is frequently met with in gardens, and is, perhaps, the most valuable of all as a town shrub. *O. macrodonta* is also a very attractive species; but while plants will come through an ordinary winter unharmed, it is liable to injury during very severe weather; therefore it is best treated as a wall shrub. Another valuable species is *O. myrsinoides*, and is undoubtedly the hardiest of the genus. Introduced from Australia over seventy years ago, it is surprising that it is not more generally cultivated. The plant forms a low-spreading shrub from 2 feet to 3 feet high, with small Holly-like leaves, being deep green

and glabrous above, while the under surface is densely clothed with a silvery tomentum. During May and June the flowers are freely borne in clusters along the slender growths, often forming a spray 2 feet or more in length. Individually, the flower-heads are about an inch in diameter, pure white, with a yellowish disc. *Olearias* are among the easiest of shrubs to manage, and while they will grow in almost any soil, they thrive best in a fairly light, well-drained compost. Most of the species may be readily increased by cuttings of the half-ripened wood inserted in pots of sandy soil during the autumn months. Considering the ease with which these beautiful shrubs are grown, it is surprising they are not more often seen. One of the most interesting groups at the Royal International Exhibition was a collection consisting of thirty-three distinct

species of *Olearia*; these were exhibited by Captain Dorrien-Smith, for which he was awarded a gold medal.

W. T.

THE DAFFODIL SEASON OF 1912.

(Continued from page 311.)

Are There Two Yellow Stripes?—I have had numerous letters telling of leaves marked with yellow stripe, or with something near akin to it, and some say that by spraying with appropriate liquids they have got the evil under, suggesting as a corollary that the cause is a fungus. If there are two yellow stripes, both have been very much in evidence during the past season.

Mr. W. F. M. Copeland writes: "I cannot make out about the disease at all. If it is not a fungus, why does it spread as I have seen it do? If it is weakness, why does it show it if the bulbs are replanted in different soil and in good soil well limed?" If I understood Mr. Engleheart aright in a remark he made at the Birmingham post-dinner note-comparing, he thinks there is only one yellow stripe, and it is caused by the plant having to live in some unsuitable environment of soil or climate. This, at any rate, is my view, and I am now going to explain the above experiences according to my theory. First, the natural growth of the plant may easily be mistaken for the beneficial effect of a fungicide. I have repeatedly noticed that in a full-grown leaf the bottom part is not nearly so much affected as the upper half. This year, for example, one of my King Alfred patches was simply awful when it was 3 inches or 4 inches high. Later on it was nothing like so bad; in fact, the parts of the leaves that Nature had allowed to remain underground until a more genial time prevailed have very little of it. Now, suppose I had sprayed when my leaves were 3 inches or 4 inches high, I might readily have ascribed the after-improvement to that, whereas it was only the natural order of things. Secondly, I do not expect

"different soil" or "good soil well limed" to work a miracle. And this it would be doing, in my opinion, if the change was "yearaneous," let alone "instantaneous." I am thankful to say I have never had blood-poisoning myself, but those who have had it have told me that their medical advisers have invariably told them to be extremely careful for three or four years. There seems to be something of the original trouble left in the system for that length of time. Just so with "yellow stripe." A plant must be given time to get out of it. Some are able to throw it off quicker than others, but I never expect the change to take place *instanter*. Give it time, even when the plant has been transferred to pastures new.

Sickle-shaped Leaf.—All Daffodil-growers know this appearance. There is often a sickly yellow

look about the leaf as well. In the earlier part of the forcing season it is not infrequent in pot-grown material. I have heard of a good deal of it this last season, both under glass and in the open. In my opinion it is largely due to a mechanical injury resulting from the sheath not working as it should do, although I do not altogether quite see why this should induce the sickly look I have referred to above. In pots it (the yellow look) seems to have some connection with the ripening of the bulb in the previous year. Late-ripened bulbs, if they are forced before their time, are very subject to it. In this connection, by the way, may I say that I notice in Messrs. E. H. Wheadon and Sons' (of Guernsey) list for 1912 that attention is drawn to the virtue of early ripening for early

was altered. A clergyman in Ireland writes that he had Grandee in bloom before either Lord Roberts or Weardale Perfection. Reference to colour will come under this head. In most districts it was decidedly above the average, but this was not the case with me. I never saw Albatross so pale, while precisely similar bulbs grown under glass had brilliant red edges to their cups. Bernardino is usually much deeper and Blackwell ditto, than they were this last spring.

Seed-bearing in 1912.—I am told that all except trumpets have given but little seed. Luckily for me, we settled last autumn to devote this season specially to them, and nearly all my seed-bearers are either trumpets or their next-door neighbours, giant Leedsis. My seed crop promises to be good, but bearing out what I am told, a fair-sized block of Princess Mary will hardly give me half-a-dozen pods. The few Poets, too, that have been hybridised have been most disappointing.

More Personal Matters.—When writing my little book on "Daffodils" this time two years ago, I devoted the last paragraph to white triandrus hybrids, and advised everyone to try to either acquire or raise some for themselves. Ever since my liking for these lovely refined pure white marble-like flowers has increased, and this last spring has still further intensified their cold beauty in my eyes. I am glad to say that they have now made their *début* in trade lists, and that many can be had for quite small sums. The very best are still dear, but as they are easy to raise from seed, I anticipate a rapid increase in their numbers and a corresponding lowering of prices. I am told that the pollen of calathinus gives much more satisfactory results, both in size and constitution, than the ordinary triandrus albus. Recipe for obtaining the same: Procure some good Leedsis or similar varieties, such as Albatross, and also some triandrus calathinus. Transfer pollen of the latter at the proper time to the stigmatic surface of the former. Collect the seed when ripe and sow in the July following. The lovely Alabaster, May Hanson and Maid Monica came from Minnie

A HARDY JUNE-FLOWERING DAISY BUSH, *OLEARIA MYRSINOIDES*.

pot culture. I never remember actually seeing it in print in a bulb catalogue before, but it is an important point, one well worth a little consideration.

Topsy-turvy in 1912.—I have had surprising results. Many varieties have turned a somersault in their behaviour. The bad have been good and the good bad. For example, Seagull was good and small, Lucifer shy, Torch about half its usual size, Evangeline poor, Apricot miserable, Weardale Perfection full of stripe, Baroness Heath rotten; while, *vice versa*, Diana was never half so good, and the ancient but most attractive and distinct variety Sir William Harcourt very vigorous and free from its usual streak. Both Eyebright and Gloria Mundi were much above their usual form. In certain gardens the usual sequence of flowering

Hume \times t. calathinus. Another item which may be a useful hint for some is the great success of the "Buco" Hand Cultivator. I find for my purpose of loosening the soil between the rows of Daffodils that the small, short-handled size is the most useful. I take the short one out and put in its place an ordinary long one. The larger five-pronged implement is also used when the rows are not very close together. I first saw these at Colonel Cotton's bulb farm at Llantair, Anglesey, twelve months ago, and they more than confirm all the flattering things he said about their working. A last word must be one about the lasting power of Pearson's Alert. It opened here this year on March 6, and it was still a flower in the distance on April 10. Can anyone go one better with a true tale of lasting?

JOSEPH JACOB.

GARDENING FOR BEGINNERS.

THE ART OF BUDDING ROSES.

BUDS are formed in the axils of leaves, in the angle between the leaf and the shoot or branch. Buds contain, in embryo, either flowers or shoots, sometimes both. The round-shaped buds generally contain flowers, and the conical-shaped or very pointed buds mostly contain a shoot only. A bud is only a tiny object, yet it will grow and form a large branch, or even a whole tree. When taken from one Rose tree and budded on another, or on the common hedge Briar or any suitable stock, it still retains its distinctness as regards variety. Budding may be done in July, also in August, but this year Roses are at least a fortnight in advance of normal seasons, and in consequence the work may be carried out within the next week or so. The proper time is when the bark separates freely from the hard wood. Never make use of a poor stock which is not growing freely, whether it be a standard, half-standard or dwarf stock. The latter must be strong, as it has such a great influence on the growing bud. If possible, select a dull day for the work of budding, and if fine rain falls so much the better. A Rose bud is a frail thing in itself; it is, after being severed from the parent bush, dependent upon the sap in the tiny portion of bark for nourishment, at least to a great extent.

Selecting the Buds.—The best are those buds growing near the middle part of a branch. If branches are cut off, they should be at once placed in a vessel of water, and the amateur will act wisely if he retains them in water and uses the buds direct from them as the latter are inserted. A shows the buds in the axils of the leaves, and the curved line denotes the way in which the buds are to be severed from the branch. It is very important that the cut be made well under the base of the bud, as shown at B, and not too close to it, as shown at C. There will be a small portion of hard wood attached to the shield or bark containing the bud, and this hard wood, O, must be carefully

SHOWING HOW BUDS ARE TAKEN OFF AND PREPARED BEFORE INSERTION.

removed, as shown at E, leaving the base of the bud, F, quite exposed but not bruised. Directly the hard wood is taken out, the bark will curve a little, as shown in the illustration at R, and it must be moistened with water immediately. G shows where the buds are to be inserted in the branches of a Briar to form a standard or half-standard Rose tree. The slits must be bark deep only, and made quite low down, as near as possible to the main stem of the Briar.

How to Insert the Bud.—H shows the T-shaped cut made in the bark; I shows the bark raised from the hard wood, and this must be done with the aid of an ivory-handled budding-knife or a smooth wedge-shaped piece of Oak. At J the bud is shown inserted. When actually putting in the

bud, cut off the top portion of bark square across so that it will fit in quite firmly. Comparatively short incisions and short buds should be the rule, as small wounds heal more quickly than large ones, and if the bark is moist when inserted it will adhere to the new branch very closely and so exclude air. Retain the leaf, or a portion of it, as it will sustain the bud for a time. New bast matting should be tied round the newly-inserted bud, as shown at K. A piece a quarter of an inch wide and 12 inches long will be sufficient for each bud. Moisten the buds night and morning with a fine spray. G. G.

PLANTING GREENS IN CLAYEY SOILS.

A HEAVY, clayey loam, when well worked and prepared, is a fine rooting medium for Greens used both for the autumn and the winter supplies I would, however, give a word of warning to those inexperienced in the growing of crops in such soils. Greens planted in unmanured, badly-worked, clayey soils rarely prove satisfactory in rather dry summers. The plants recover somewhat when the autumn rains come, but in the meantime the leaves turn very blue and become hard, and then the hearts do not grow as large nor as tender as they should. Thoroughly break up the sub-soil and mix some rotted manure with that portion lying about four inches below the surface. The top soil then remains more open and is warmer. A clayey soil is not at all difficult to work after a heavy shower of rain has fallen on it when it has been for a short time lying dry and hard. When the plants are put in, however, the ground must be rather dry; then, if they are watered immediately, they will grow very freely. Use the hoe often between the rows of plants, and so keep the surface open, prevent cracking, and kill weeds while in a small state. So treated, the crops will be heavy. B.

BRIAR STOCKS BEFORE AND AFTER BUDDING HAS TAKEN PLACE.

GARDENING OF THE WEEK.

FOR SOUTHERN GARDENS.

The Kitchen Garden.

Winter Greens.—Continue to plant these in variety for producing a plentiful supply during the winter months. Where space does not permit of a piece of ground being set apart purposely for them, they may be planted between other crops that will not occupy the ground too long, such as winter Onions and Runner Beans. Select showery weather for planting, even though the ground is firm, this will be found to be so much the better, and the plants will make sturdier growth and be better able to stand the cold. When the first crop is cleared, just fork over the ground between the rows of winter greens.

Peas.—It is not generally advisable to sow after this date, though in a congenial season a small sowing of a suitable variety will provide some good dishes. Essex Wonder is a good variety and prolific cropper. Continue to stake earlier sowings as they require attention. Stake firmly and neatly, and clip off the tops to the desired height according to the variety.

Turnips.—Make another sowing or two, according to the requirements, in drills 1 foot apart, and if the weather is dry cover with short lawn mowings, as I think I have previously advised. These are an excellent preventive against the Turnip flea. Keep the surface soil well hoed between growing crops, and dust with soot in showery weather.

Globe Artichokes.—These will benefit, if the weather is hot and dry, by a good soaking of water and the addition of liquid manure-water.

Plants Under Glass.

Panicum variegatum.—A fresh batch may soon be obtained by inserting cuttings, say, five or six, round the edge of a 3-inch pot and well watering in. For a week or two these may be stood in the shade in a warm house. The same applies to Tradescantias, Fittonias, Pileas, Selaginellas and other like subjects.

Cyclamen.—The young plants will by now be ready for their final shift into the pots in which they are to flower, and 5-inch pots will be large enough to produce good plants. A compost of good fibrous loam, with a fair proportion of flaky leaf-mould, a little sharp road grit and bone meal, will answer well. Pot fairly firm; leave the corm showing well above the level of the soil when finished. Water well after potting, but avoid over-watering afterwards until roots are active. Stand the plants on a good, firm ash bottom well sprinkled with soot. Keep the surroundings moist, give plenty of air, and shade from bright sunshine, but not too heavily.

Herbaceous Calceolarias.—For greenhouse and conservatory decoration these are beautiful subjects in the spring and early summer months, and when a good strain is selected, the colouring of the flowers is most varied and beautifully marked. Sow the seed thinly as level as possible, on the surface of a pan filled with a fine compost, and just cover with some sandy soil. Well moisten, as previously recommended, by immersing nearly to the rim in water. Stand in a shady place, cover with a sheet of glass, and further shade when sunny with paper. The seedlings when large enough will need carefully pricking off, and must be placed where they will be free from attacks of slugs. Keep the surroundings throughout their season of growth moist and cool.

Streptocarpus.—The seedlings that were sown early in the year and pricked off into boxes will now be large enough for potting singly into 3-inch pots, and possibly a few of the more vigorous into a size larger. The plants will then soon commence to flower, but, unless particularly wanted for decorative purposes, they will make better growth if the flower-spikes are removed.

Fruits Under Glass.

Strawberries for forcing next season for the earliest batches need to be thoroughly matured early, so that when enough runners are to be obtained sufficiently large, layering may be proceeded with. Three-inch pots are best for the purpose, though some growers favour layering direct into the fruiting pots. When the former method is adopted, use clean pots, so that they

knock out readily. One crock is sufficient, and a compost chiefly of loam will answer well. Stand the pots, as many as needed, round the parent plant, then slightly bury the runners and peg down. Various methods are adopted, including wire pins, some growers fastening with a stone; but one of the best I know, where a quantity has to be done, is to take a bunch of thin Willow or Spiraea sticks cut last winter and put them in a tank of water for twenty-four hours; cut up into lengths of about three inches and bend double as wanted. Avoid over-watering, but damp over twice daily when the weather is warm and dry.

Melons.—When the earliest fruits have been cut, and it is the intention to plant the house again, have the whole of the contents removed and give the walls a thorough whitewashing, well cleansing the glass and woodwork before building up another bed.

The Hardy Fruit Garden.

The Rain.—Since writing the last calendar we have had some welcome showers, which have had a good effect on all hardy fruits, both in cleansing the growths and supplying water at the roots. At intervals the application of a quick-acting artificial fertiliser on swelling crops will be advantageous.

Figs.—Look over the trees and remove weakly shoots where the growth is crowded, and secure the newly-made shoots either by nailing or tying with broad strands of raffia. Avoid having these tied too tightly.

The Flower Garden.

Verbenas.—As the growths lengthen, peg them down, and remove the flower-buds for a time to encourage growth. Keep the surface soil stirred between the plants.

Michaelmas Daisies.—These are now growing apace, and the growths will need securing to the stakes with raffia. The longest of the growths that are running away may be stopped, but otherwise these will be better for not doing so, as the plants will be fully branched at flowering-time where five or six growths are allowed to remain. Keep the Dutch hoe moving frequently between them to encourage growth and eradicate weeds, and during showery weather a dusting of soot or fertiliser will be beneficial. If any signs of mildew appear, syringe the plants with an insecticide, such as Quassia or some other specific. The Amellus section, though dwarf, are better for having the main growths loosely supported to a single stake.

Mignonette.—Thin as becomes necessary and make another sowing. Among the Roses this is generally much appreciated.

E. BECKETT, V.M.H.

Aldenham House Gardens, Elstree, Herts.

FOR NORTHERN GARDENS.

Shrubs.

Rhododendrons.—It is usual to relieve the finer varieties of plants of seed-vessels, which is undoubtedly a great help towards enabling them to produce and mature shoots to flower another year. Attention should at the same time be given to the stems, lest suckers from the stocks should be draining the plants of their sustenance. Some prune at this time, but pruning must be done with much judgment and only on healthy, vigorous plants.

Dead Wood.—I never remember so many branches, and in the case of Hollies so many plants, to have died since spring, which may be only the effect of last year's drought, but probably also of the very hard frost in January. Besides being unsightly, dead wood is very harmful to the living shrub, and it is therefore very important that an effort should be made to remove it at the earliest moment.

Flowering Shrubs.—Seldom, if ever, have these been more floriferous than this year, and some that have failed to flower hitherto have this year done so. Of such may be mentioned Xanthoceras sorbitolia, Pyrus Manlei, if at all crowded with shoots, should be relieved of a portion. Choisya ternata also may be lightly thinned and pruned into shape, should the bushes be growing one-sided, which they have a tendency to do. Overgrown Scotch Roses may now be cut to the ground, consequent on which they will, like Willows, make

long shoots for next year's flowering. Hedges of Sweet Briar grow very rapidly at this time, and must not be allowed to go untrimmed.

The Hardy Fruit Garden.

Breast-Wood.—Continue to relieve all kinds of trees of superfluous growths. Red Currants may have their shoots shortened, and should aphid attack Gooseberries, the parts affected may be cut off and burned at once.

Figs.—These will now need attention, and new growths should be selected to lay in for cropping another year. The shoots must not be permitted to extend outwards, but laid in close to the wall in order to obtain all the heat possible.

Grafts.—The ties on these should be removed, and if it is considered necessary, others substituted for them, so that the bark may not be cut. The number of shoots, where too many have pushed, must also be reduced to a proper number. This will give those left all the sustenance available and make them much stronger in consequence.

Apples.—About this time American blight shows itself, and means must be taken, if not to exterminate it, at least to keep it under. Syringing very forcibly with hot water, or that strengthened by soft soap and petroleum or a little salt, is a simple but fairly efficient disinfectant for summer use. Irish Peach, which sets in clusters, may now be thinned somewhat freely if large fruit is expected or desired.

The Vegetable Garden.

Cauliflowers.—Seeds of a second-early variety sown now will provide nice medium-sized heads for using in late autumn.

Large Onions.—Repeated surface-dressings of stimulating manures are almost essential to the production of these. A fortnight may be allowed to intervene between them. A rather deep surface-hoeing subsequent to application is of great benefit. Winter Onions should be harvested as soon as ready.

Brussels Sprouts.—The earliest and largest of these should have a bank of soil applied to each side of the drill. The drills being 3 feet wide, a spade, should the ground be hard, is the best implement for the operation. This, moreover, loosens the soil to a far greater extent than is possible with an ordinary draw-hoe. Usually stimulating manures are hurtful to this crop, that is, if small, hard sprouts are the objective of the cultivator.

The Flower Garden.

Violas.—Particularly on light soils these have a tendency to go to seed, and then to become quickly "seedy." The cure for this is to pick off all the flowers and seed-vessels, following which the unopened buds will make the beds as gay as ever in a few days and the plants be enabled to retain their freshness.

Seed-Sowing.—It is the usual practice to sow Hollyhocks about this time, in order to secure strong flowering plants for another year. There is still time to sow Humea elegans, also Celsia coromandelina, C. pontica, Delphiniums and many more hardy plants.

Dahlias.—To have these, especially plants from old roots, dwarf, keep pegging down the shoots, at the same time cutting away weakly parts. The earlier plants will be now well forward to bloom. Those from cuttings, as a rule, are best staked, and these will now need attention at very short intervals. See that the thickening stems are not being cut by the ligatures made earlier in the season.

The Plant-Houses.

Seed-Sowing.—Canterbury Bells and Campanula pyramidalis intended to be flowered in pots next summer should be sown without further delay. A few potlins of Mignonette may also be sown for autumn. These are best grown on single stems and several in a pot, using a very open, rich soil. It is always advantageous to cover the surface with some material that at once darkens the seeds and keeps the soil from drying.

Climbers.—There will be much labour in tying climbers and arranging the shoots so that they do not encroach on each other, a condition that is not only bad for the plants, but renders the keeping of them clean very difficult, insects invariably being attracted thereto. The strong young growths of Lapagerias sometimes are eaten by slugs, an occasional dusting with soot being effective in keeping these off.

R. P. BROTHERSTON.

Tynninghame, Prestonkirk, N.B.

THE NARCISSUS FLY.

DURING the last few years the two-winged fly, called by scientists *Merodon equestris* (the latter name having nothing in common with horses), appears to be increasing in numbers in this country. It is called the Narcissus fly, but lately has been attacking other than Narcissi, and I myself know that it has attacked *Scilla* bulbs. It has already caused much damage by destroying bulbs of Narcissi, and latterly *Lilium*s, and my idea now is that it may attack other members of this family.

The life of this insect is as follows: During the end of May and June, according to season and climatic conditions, this two-winged fly is on the wing, and may be seen in bright sunshine basking on the leaves of Narcissi and other plants. The female lays the eggs between the leaves at the surface of the ground, and the young grub, which is almost identical in appearance to the house-fly or blow-fly maggot (to which it is closely related) travels down and burrows its way into the bulb, where it is feeding during the time the Narcissus is forming its bulb growth for the season. It remains in the bulb in the hollow which it has eaten out, and during early spring it transforms into a chrysalis or puparium. The puparium is usually the colour of the soil, and is shaped almost like a horse-bean, but with grooves and ridges on the incurred side, leaving the Narcissus bulb (which it has usually killed) and hatching out at the end of May and early June. The fly belongs to the diptera or two-winged flies, to which, as I have said, the house-fly and bluebottle, or blow-fly, belong.

This is a well-known insect on the Continent, and may be as well known here if precautions are not taken to keep it in check. In size it is about half an inch long, with very large eyes and very strong legs, and may be easily distinguished from the bee by having only two wings, which are folded along the body, hiding it, and by its not having longish black antennæ or horns, which all bees have. The large eyes are black, separated with a short, stiff line of dark gold hairs; the wings are transparent and attached to the large body; the abdomen is densely covered with short, stiff hairs, dark gold, and the insect looks, at the first glance, like one of the small black and tawny bees, but may at one glance be distinguished from them by its having only very short and hardly noticeable antennæ or feelers. The antennæ are the most easily noticeable difference, but it has also only two wings, while bees have four. It sings with rather a high note when disturbed.

J. HENRY WATSON.

THE EDITOR'S TABLE.

Pæonies from Langport.—The arrival of a box of handsome Pæonies sent by Messrs. Kelway and Son of Langport serves to remind us of the usefulness of these hardy flowers at this season. Pæonies are foremost among plants for the flower garden. No herbaceous border is complete without them, and they are equally at home by the side of grass walks or in a woodland garden. Moreover, Pæonies lend themselves in a most pleasing way for distant effects, while as cut flowers they are extremely useful for house decoration. The hardness of the Pæony is proverbial. Indeed, it is claimed to be as hardy as the Dock by the wayside, thriving in any soil without need of protection in the severest weather. Among the

flowers sent we were particularly impressed with those of the new section known as the Imperial. These flowers are noteworthy for their delicate tones and beautiful art shades. Unlike both single and double varieties, those of the Imperial section have outer shell-like guard petals surrounding a rosette of petaloids and golden filaments. The variety A. M. Kelway of this section is most charming, and the same may be said of Queen Alexandra, a lovely flower of absolute purity of colouring, resembling an open Water Lily, with outer petals spotless white, and golden clusters of anthers within. The truly double flowers are as popular as ever, and the variety Emperor of Russia, a magnificent deep purple-crimson, should find a place in every garden where these flowers are prized. Exquisite, another double variety with handsome pink flowers, and Mr. Manning, a very deep crimson, are among the best of the doubles now before us. The single varieties are always welcome, and Purple Emperor, a deep rosy purple of wonderful size, is one of the most beautiful we have ever seen. We remind our readers that now is the time to make a selection and plan their borders for autumn planting.

ANSWERS TO CORRESPONDENTS.

RULES FOR CORRESPONDENTS.

QUESTIONS AND ANSWERS.—*The Editor intends to make THE GARDEN helpful to all readers who desire assistance, no matter what the branch of gardening may be, and with that object will make a special feature of the "Answers to Correspondents" columns. All communications should be clearly and concisely written on one side of the paper only, and addressed to the EDITOR OF THE GARDEN, 20, Tavistock Street, Covent Garden, London, W.C. The name and address of the sender are required in addition to any designation he may desire to be used in the paper. When more than one query is sent, each should be on a separate piece of paper. Plans for naming should be clearly numbered and securely packed in damp grass or moss, not cotton-wool, and flowering shoots, where possible, should be sent. It is useless to send small scraps that are not characteristic of the plant. Letters on business should be sent to the PUBLISHER.*

FLOWER GARDEN.

SWEET PEAS NOT DOING WELL (E. T.).—You should immediately pull out and burn the unsatisfactory plants. We have no sympathy whatever with the preparation of the soil in trench form, and should be inclined to think the roots have reached rank manure. If the soil used was new, it would cause the trouble. We cannot conceive that the soil is sour in such a season unless it was excessively manured and imperfectly cultivated. Lime will be advantageous as far as the soil is concerned, and it will not injure the plants.

DIVIDING IRISES (A. G.).—Irises should be divided and replanted in spring, preferably March or early April. Avoid planting them in big clumps, since better results follow upon free division and replanting in well-prepared soil. *Iris stylosa* prefers a hot, sunny position at the foot of a warm wall, and much old mortar or lime rubble mixed with the soil. *Iris sibirica* is a moisture-loving species, and should be catered for accordingly. Herbaceous Pæonies should be divided and replanted in August or September. The subjects should never be transplanted in big clumps intact. The Tree Pæonies should be planted during September or October, preferably while the soil is warm.

SWEET PEAS FOR EXHIBITION (Alpha).—Your collection is comprehensive, but several varieties of conspicuous merit are omitted. You do not say how many varieties you desire to give special attention to with a view to exhibition, so thirty are herein specified, which would enable you to exhibit in a class for twenty-four distinct. In your district (Caithness) we should expect the plants to reach their best about the middle of August, but much depends on the weather. The chosen varieties are: John Ingman, Paradise Ivory, Mrs. Henry Bell, Etta Dyke, Elfrida Pearson, Mrs. C. W. Breamore, Earl Spencer, Mrs. Roubtahn, Asta Ohn, Countess Spencer, Mrs. Cuthbertson, Dobbie's Cream, Loyalty, Mrs. Heslington, Nubian, Hercules, Money-maker, Clara Curtis, Eric Harvey, Mrs. W. J. Unwin, Barbara, Doris Usher, Charles Foster, Edrom

Beauty, Thomas Stevenson, Maid Holmes, Scarlet Emperor, Edna Unwin Improved and Flora Norton Spencer.

JAPANESE IRISES (P. W.).—Prick out the seedlings by all means, in a richly-prepared bed of soil, selecting a position of some shade and where moisture is assured or readily supplied. The soil these things prefer should be of loam, leaf-mould and manure with a little sand, the whole to be passed through a sieve of half-inch mesh and well mixed. Do not attempt a raised bed; these plants love moisture. If given fair or liberal treatment, the plants should have progressed sufficiently to be given their permanent quarters in April, 1913. Usually three or four years are necessary before the flowering stage is reached, and even then it may not be characteristic or good. How good will depend not a little upon the liberality of their care, and not a little also upon the strain from which the seedlings have come.

ORIENTAL POPPIES FAILING (N. H.).—It is curious that the plants appeared all right through the winter and have since made but little progress, and we fear there is an influence at work, apart from the fact that your garden is a town one, that we know not of. These plants do much the best in the open border, and, once established, will go on for years without trouble or care. In the young state the growth is meagre, and we are wondering whether as non-flowering plants they have not practically completed their growth for the season. In all the circumstances, we can only advise you, a little later on, to carefully remove the soil about the plants to see if they are alive and well at the root, and, if so, to possess your soul in patience. If you have more than one plant, there would be no great risk in lifting one for examination at any time, and you might let us see it. Without some such evidence we can only speculate as to the cause of failure, and the behaviour of your plants points to something more than the period of shade to which you refer.

PROPAGATING PHLOX SUBULATA AND SUN ROSES (H. P.).—There should be little or no difficulty in propagating these plants if the right material at the proper season is obtained. After flowering is well over, slightly shorten back the growths of the plants with scissors or knife, and give attention to watering, so that a new growth quickly results. In a few weeks' time, when the new shoots are about two inches in length, they may be stripped (not cut) away from the parental stem in such a manner that the "heel," or junction with the stem and cutting, is fully reserved to the latter. In this way, without further ado, the pieces may be inserted in a cold frame in very sandy soil. Cuttings such as these may be inserted from July to September, or even later. Much the same principle should be applied to the other groups named, though these root freely and well when the cuttings are made to a joint in the ordinary way. The thing to aim at is a cutting of youthfulness and vitality, old flowering shoots being usually of but little value. August and September are the best months for the latter group, and cold-frame treatment will be found much the best.

THE GREENHOUSE.

CULTURE OF GERBERA HYBRIDS (Anxious).—As far as we can learn by your letter, there is nothing whatever wrong in the culture of your Gerberas, unless, perhaps, it be the inclusion of burnt refuse in the potting compost. Still, although we have not seen it used for the purpose, we do not consider it would do any harm. You say nothing as to the time when the seed was sown nor the size of the plants. One point to bear in mind with regard to the successful culture of Gerberas is that, although the seed germinates very quickly, the young plants grow slowly afterwards. During their earlier stages the root progress is by no means rapid. The temperature named by you is very suitable for these pretty flowering plants, and if they are given a reasonable amount of water, we think they will soon grow away freely and ultimately flower. They are certainly plants that will take their own time, and they cannot be hurried with additional heat. Should our surmise as to growth soon taking place not be justified by results, we should like to hear further from you, giving us fuller particulars.

FRUIT GARDEN.

PEAR LEAVES ATTACKED (J. C. W.).—The Pear leaves are attacked by the Pear leaf-bliester mite (*Eriophyes pyri*). This mite is probably carried from tree to tree on the feet of insects. Spraying with Oregon wash is probably the best remedy, and it should be applied in winter. Nicotine spraying might probably with advantage be tried now. If only one tree is affected, and that in a pot, it would probably stop the spread of the plague to destroy that tree. It would be better to use lead arsenate paste instead of Paris green against the caterpillars, as there is less danger of injuring the foliage with that.

STRAWBERRIES NOT FRUITING (J. R.).—From what you state in your letter, there does not appear to have been a single item of culture likely to secure the best results omitted in your case, and therefore it is difficult to suggest what the cause of failure has been. The complaint is general this season of inexplicable failures with Strawberry crops, in pots under glass as well as out of doors. We can only come to the conclusion that the great heat and drought of last year are at the bottom of the trouble. In many parts we know that the growth of the plants was seriously crippled. In fact, on warm, light soil in many parts (where watering could not be resorted to) the plants were killed outright. We all know that, in the absence of a strong and healthy growth of the plant during the previous year (after fruiting), the chances of good crops the following year are greatly lessened,

because it is quite impossible to have a healthy and full development of the flower-buds, or crowns, in the absence of this free and healthy growth the previous summer.

KITCHEN GARDEN.

MILLEPEDES AND ONIONS (G. W.).—The animals sent, attacking the Onions, &c., are millipedes (*Julus complanatus*). Unless the use of the water from the cess-pool has caused the soil to become sour, a condition which can be corrected by the use of lime, we do not think it has had much to do with the millipedes. We should recommend you to try Vaporite or Apterite, or some such soil fumigant, which will probably drive away the pests, and in the autumn give a dressing of lime to the soil.

ABOUT PEAS (Gowland).—The little lumps on the roots of the Peas are not a symptom of disease, but the outward and visible sign of the inward presence of numerous bacteria which take nitrogen from the air and pass it on to the plant so that it may be used by it. They are of great advantage to the plant. The Peas have been killed by the fungus *Thielavia basicola*. The fungus seems to thrive best where the drainage is not thoroughly efficient and where the plants have been exposed to some weakening influence. Thorough drainage, thorough cultivation and a sufficient supply of potash and phosphates are essential to success.

CAULIFLOWERS AND CATERPILLARS (X. Y. Z.). Yes; the caterpillars found in the Cauliflowers are usually those of the white butterfly. The means of checking them are the capture of the butterfly, destruction of the eggs, which are laid on the under side of the leaves, hand-picking the caterpillars, and spraying with salt water (say, a handful of salt in two gallons of water). Mosquito netting spread over the patch will be of material assistance. The destruction of the chrysalides, which may be found in crevices in walls and against fences in the winter, is an important measure. The growing of Cabbages and Cauliflowers in clean situations, away from fences and hedges, is also important.

PREPARING MANURE FOR MUSHROOM-BED (W. T. H.).—The manure would cool as much in an hour if spread out thinly on the ground as it would in a longer time. Probably your manure is too dry, and does not decay in the process of fermentation as it would do if it contained more moisture. The hot weather at the present time helps to keep the temperature high. In any case, seeing that the manure has been in preparation so long, we would now make it up into a bed. If it is dry, let it be turned over first and slightly moistened with water, and then made into a bed as directed, in the driest and coolest position you have in the garden. Spawn immediately the thermometer drops to 80° Fahr. on the surface of the bed. If you can make a rough framework of stakes over the bed and cover this with any odd mats or other available material, in order to keep it cool and dark, it will help the bed much during the summer, as Mushrooms do not like too much heat at any time.

MISCELLANEOUS.

THE YELLOW-FLOWERED CHERRY (Mrs. A. H.).—October is a good time for planting the yellow-flowered Chinese Cherry (*Prunus serrulata flore luteo pleno*). It may be obtained from Messrs. Veitch, Combe Wood Nursery, Kingston Hill, Surrey. The specimen sent for examination is *Ceanothus veitchianus*.

RED GROWTHS ON LIME LEAVES (D. M. M.).—The peculiar reddish growths on the Lime leaf are due to the presence of mites, which cause irritation to the plant and induce the formation of galls having the curious "nail-like" appearance and the red coloration which these show. The mite is fairly common; it may be seen, if the gall is cut open and magnified, living among the hairs in the interior of the gall.

VARIOUS QUESTIONS (E. M. S.).—(1) Grow five in a 5-inch pot. If you want the plants to flower early, do not stop them. If you want to make them more bushy and to flower later, stop them, or pinch them back, as you term it. This should be done as soon as the plants restart freely into growth after being potted. (2) Yes; certainly. Now is a good time to apply it. (3) Royal Albert is still one of the best for early forcing. Victoria is still excellent. Daw's Champion is a comparatively new variety, of great excellence in every respect.

BOX OF LARVÆ (N. B.).—The grubs are those of the clay-coloured weevil, which is now turning into the chrysalis state. They are very destructive to the roots of many kinds of garden plants, and extremely difficult to deal with on a large scale. It would be well to try to capture as many of the beetles as possible. They are, as the name suggests, the colour of the soil, and leave the latter during the evening to feed on the leaves of plants, on bark of trees and the young shoots of Raspberries, Vines and so on. They may then be made to fall on a sheet spread beneath the plants they attack, and may so be captured. The same result follows if a light is suddenly thrown upon them. They are about three-eighths of an inch in length, and have very hard skins. Next to hand-picking, the best method of dealing with them while they are in the soil is to inject carbon bisulphide, at the rate of about one ounce to the square yard, into the ground they are haunting. This is a very poisonous and inflammable compound, and must be used with great care. The fumes will spread through the soil and kill all animal-life; but unless the liquid comes into actual contact with the roots of the plant, the plant itself will not be injured in any way. Where the ground can be turned up, the insectivorous birds, such as starlings, robins and so on, will do much to check the pest.

LEGAL POINTS.

Fruit, Birds and Curtilage (F. V. H.).—A correspondent whose fruit is suffering from the depredation of birds asks whether shooting is allowable if they are within the curtilage. The Wild Birds' Protection Acts, 1880 to 1890, prohibit killing between March 1 and August 1 certain scheduled birds, such scheduled birds being chiefly those which are rare and becoming extinct. I do not think he has much to fear from this series of Acts, and I think his question is rather directed to shooting without taking out the ros. gun licence. By 33 and 34 Vict. c. 57, a penalty of £10 is imposed on every person who shall "use or carry a gun elsewhere than in a dwelling-house or the curtilage thereof" without having in force a gun licence. The expression "curtilage" includes the yard, offices, and enclosed garden surrounding the house, but it does not include an orchard separated from the house by an enclosed yard. Apart from the curtilage question, a gun can be used for the mere purpose of "scaring," but not for the purpose of killing birds.

Land, Further Purchase and Deeds (Rusticus).—A person who has bought and taken a conveyance of a piece of land is thinking of buying some more from the same owner, and wishes to know whether further conveyancing is necessary, or whether the former conveyance could be altered. The latter alternative must not be adopted. It may be an ingenious idea to save expense, but it would be a material alteration inconsistent with the original purpose of the deed which would make the previous deed void, even if it did not expose the parties to a prosecution for forgery or an offence against the Stamp Acts. Our querist, if wise, should go through the somewhat dreary performance he did on the former occasion, namely, after signing the contract and delivery of abstract, take the papers to his solicitor, who will investigate the title and prepare the conveyance, &c. Although the owner may be the same, the title to the new acquisition may be entirely different.—BARRISTER.

BOOKS.

Wild Flowers of the Hedgerow.*—The little volume before us is the first of a series of "Wild Flowers in Their Homes," and, so far as it goes, is well done. We make the remark advisedly, inasmuch as we should have liked to have seen the generic and specific names bracketed with the common or popular names of the plants as these appear either in the illustrations or in the text. The names are so given in the index, and to the student of wild flowers, as well as to the general reader, it would have been a greater convenience had they appeared as suggested. We hope we are not expecting too much in a book the cost of which is but 1s., though information of the kind we have in mind adds greatly to the general utility of such a book. The contents is comprised in three main chapters, "Wild Flowers of Spring" (March—May), "Wild Flowers of Summer" (June—July) and "Wild Flowers of Autumn" (August—September). Between seventy and eighty species and genera are dealt with, and much useful and reliable information is imparted. There are also about a score of illustrations of wild flowers in

* "Wild Flowers of the Hedgerow," illustrated, by W. Percival Westrell, D.Sc., F.L.S. London: T. Werner Laurie, Clifford's Inn.

black-and-white, and some half-dozen coloured plates, which are beautifully and naturally done.

Making a Fruit Orchard in British Columbia. The author of this excellent book, who states that he is most concerned with the Apple, strongly advises against the purchase of land in that colony without it being first seen, especially as it varies greatly in quality in even limited areas. Situation, drainage and aeration also are matters of importance. Thus, a deep, flat position with bad aeration suffers from frosts; on the other hand, the side of a moderate slope is good, especially if there is a suitable soil. A north-west aspect is preferred, but where winds sweep coldly it is wise to plant breaks in the form of Norway Spruce or Lombardy Poplar to counteract the wind force. If a stream or lake is contiguous, the effect on the atmosphere is good. But in selecting sites for orchards some consideration has to be given to communications by river or rail with a town, otherwise getting produce to market or obtaining supplies may be very costly. So much sums up the pith of the introductory chapter of the book, as it includes valuable information to the intending fruit-rancher in a concise form. It is obvious that the author writes in an absolutely impartial way, and seeks to show emigrants what are the pitfalls to avoid, as further on he gives wide information as to all that has to be done once the ranch is started. In the chapter devoted to "Soils, Rocks, Water and Timber," more complete evidence of the need for personal inspection of sites is furnished. The author deals fully with land prices and the amount of capital required to start ranching. Lack of such knowledge has in the past brought many a good man to grief. Then the cost of labour in clearing land, especially of tree stumps, is shown, and reading his information as to blasting operations, the use of chain and pulley tackle, and stump-burning, we cannot envy the settler on such land or regard his lot as a happy one. The first few years of such a life must be very hard work and almost slavery. What are described as surface crops to utilise the land while the trees are growing, Potatoes and Onions especially seem to be the most profitable. Bush or soft fruits may be grown in moderate quantities, unless very convenient markets are at disposal. Poultry pays well if kept secure from predatory enemies. The best varieties of Apples to grow are mentioned, and the selection shows that supplying the British market is fully considered. Short selections of Pears, Plums, Peaches and Cherries are also given; but these play very minor parts to the Apple. Proper methods of planting trees, with descriptions of cultivation and management, follow home methods very closely. The same may be said with regard to pruning, a subject very difficult to instruct the novice in, unless he can attend ocular demonstrations. Proper spraying of orchards with fungicides and insecticides is emphasised, showing that, brilliant as the climate of British Columbia may be, it creates many troubles for the fruit-grower. We strongly commend this book to all intending emigrants to British Columbia whom its contents may specially concern. It should be a pocket companion to them on the voyage out. It is the sort of book to set all such thinking, as well as to furnish them with preliminary knowledge which it would be folly to ignore. The book is written purely in the interests of the intending settler, and as such it merits all praise and all confidence.

EDITORIAL NOTICES.

Every department of horticulture is represented in THE GARDEN, and the Editor invites readers to send in questions relating to matters upon which they wish expert advice.

The Editor welcomes photographs, articles and notes, but he will not be responsible for their safe return. All reasonable care, however, will be taken, and where stamps are enclosed, he will endeavour to return non-accepted contributions.

As regards photographs, if payment be desired, the Editor asks that the price required for reproduction be plainly stated. It must be distinctly understood that only the actual photographer or owner of the copyright will be treated with.

The Editor will not be responsible for the return of artistic or literary contributions which he may not be able to use, and the receipt of a proof must not be taken as evidence that an article is accepted. Publication in THE GARDEN will alone be recognised as acceptance.

Offices : 20, Tavistock Street, Covent Garden, W.C.

NOTES OF THE WEEK.

Sir Alexander Cross, Bart.—On the next page appears a portrait of Sir Alexander Cross, on whom has been conferred the honour of a baronetcy, as announced in our issue last week. Sir Alexander is the senior partner in Messrs. Alexander Cross and Sons of Glasgow.

Rose Mme. Isaac Pereire as a Pillar.—When visiting the beautiful Rose garden at Chalkwell Park, Westcliff-on-Sea, last week, we were pleased to find this delightful old Rose grown in pillar form. The pillars were laden with the large, old rose coloured blooms, and were free of the green centres that sometimes mar the beauty of this variety. For the sake of its fragrance alone this old Rose is worthy of a place in any garden. In the autumn, when the sun is not so powerful, the colour of the blooms is almost cherry red.

Crassula coccinea.—This plant was introduced as long ago as 1710, and though numerous species have been brought to this country since then, and various hybrids between this and others have been raised, yet a good form of the true coccinea stands out superior to all of them. The fact that it has at least for the last half century been a favourite subject with the market-grower, and still holds that position, is proof positive that it is a really good thing. It is a plant of simple requirements, and one that, owing to its succulent nature, must not be over-watered during the winter months, at which time all that it needs is a temperature suitable for a Pelargonium. The nomenclature of this good old plant is somewhat confusing, for while it is usually known as above, yet it is sometimes met with as Kalosanthos coccinea, and in the "Kew Hand List" it is given as Rochea coccinea.

The Australian Bluebell Creeper (Sollya heterophylla).—The popular name of this slender-growing ligneous climber is a very appropriate one, as the bell-shaped flowers are of a delightful shade of blue. While it may be treated as a wall plant in the favoured parts of these isles, the protection of a greenhouse is, in most parts, necessary to its well-doing. In that structure it may be grown in different ways, as, if the house is not a lofty one, it has an exceedingly pretty effect when trained to the roof or rafter, the drooping blossoms being then seen to the best advantage. Besides this it may be grown in pots, and the slender shoots twined around a few sticks. In this way it will flower profusely, and that, too, over a lengthened period, while flowers of that tint are appreciated by everyone. This Sollya may be readily struck from cuttings of the young growing shoots, put into sandy soil and placed in a close propagating-case kept at a warm greenhouse temperature. It prefers a certain amount of peat in the potting soil. The late Mr. J. H. Veitch, in his

"Traveller's Notes," mentions that while he met with this Sollya freely in Western Australia, it was always as a dwarf bush and not as a climber.

The Namaqualand Daisy.—This beautiful little low-growing annual is doing better this year than we ever remember seeing it before. Plants that were raised from seeds sown in a cold frame at the end of March commenced to flower as soon as planted out the third week in May, and look like continuing the display right through the summer. The beautiful glossy, orange-coloured flowers resemble those of the Gerberas in shape and gracefulness. We have them planted between the Roses in a bed made up of such yellow varieties as Arthur R. Goodwin, Duchess of Wellington and J. Coey, and the effect is most pleasing. Owing to their shallow rooting they do not rob the Roses of much food, and are much better for Rose-beds than Violas. It is a pity that the common name of this annual is almost as unwieldy as the botanical one, viz., *Dimorphotheca aurantiaca*.

Spiræa decumbens as a Wall Plant.—*Spiræa decumbens* is a recognised favourite in the rock garden, where its pretty foliage and clusters of white flowers are always welcome in their season. It is considerably less known as a wall plant, but it may be grown with the greatest success on a wall with a considerable body of soil behind. At Monreith there is a capital plant under such conditions in the wall garden, and it was very pleasing indeed there. The difficulty with this and many other plants suitable for a wall is that of establishing it, and for the purpose young plants are best. If the wall is properly constructed, a stone may be taken out and the *Spiræa* put in with the ball of soil attached, and then a stone well jammed in about it, but so placed that any water which may fall on the wall will run towards the roots.

A Yellow-Flowered Tree Pæony.—From the firm of M.M. V. Lemoine and Son, Nancy, France, we have just received a coloured illustration of a fine double yellow-flowered Pæony raised at their establishment between the now fairly well-known *Pæonia lutea*, a native of China, and a variety of *Pæonia Moutan*. The new-comer, which bears the name of La Lorraine, has, according to the illustration, a large, full flower, which, when first opened, is of a soft sulphur yellow with a salmon tinge. It has gained high honours in France, and it is a pity it was not shown at the recent "International" here, for, according to M. Lemoine, it was grown for the show, but, unfortunately, three days of tropical heat caused the buds to expand suddenly a week too soon. This is certainly to be deplored, as good new plants were none too numerous at the "International," and so many highly meritorious subjects have emanated from Nancy that one may look forward with confidence to this Pæony making its *début* here.

CORRESPONDENCE.

(The Editor is not responsible for the opinions expressed by correspondents.)

Birds and the Fruit Crop.—Will you allow me to suggest to the bird-lovers among your readers that during the summer season they should make a point of periodically visiting their fruit-nets, and so ensure against such of our little songsters as may have been caught there dying a slow death by hunger and thirst? It is quite a common thing to find the dead body of a bird entangled in the meshes of a Strawberry-net, and one does not like to think of the lingering death by which the little thief has atoned for his very natural greediness.—Z.

The Naming of Roses.—Under this heading (see June 15, page 304, and June 22, page 314) your correspondents protest—and that by no means too strongly—against a practice adopted by some American florists of giving fresh names to already well-known Roses. Our cousins across the Atlantic may perhaps accuse us of being the first to originate this system of the changing of names. In the eighties, when there was such a demand for new Chrysanthemums, a good deal of this was done, not only in the case of varieties from the States, but also those from France. Some of the varieties sent out by M. Delaux were very harshly dealt with in this respect, among those which I can just recall to memory being Jeanne Delaux, which was renamed F. A. Davis, M. John Laing called M. J. J. Hillier, Tricolor changed to Mr. J. Starling, and Source Japonaise to R. Ballantine.—H. P. [The practice of re-naming varieties already in commerce and disseminating the same as new varieties is dishonourable and cannot be too strongly condemned. If trade growers, either in this country or abroad, are to enjoy the confidence of the gardening public, this evil must be stamped out at once. Unfortunately the practice is not confined to Roses and Chrysanthemums, other instances, notably among Sweet Peas and herbaceous plants, also among Alpines, Orchids and fruits, have recently been brought to notice. It is in the interest of trade growers and the gardening public that we give this matter prominence in our columns.—ED.]

The Cherokee Rose.—In the issue of THE GARDEN of the 15th inst. I see that the Cherokee Rose is mentioned as originating in the Himalaya. I have always been under the impression that this Rose was a native of the Southern States of the United States. I have an idea that this Rose was so named by the Cherokee Indians, who are a tribe of American Indians. I cannot be sure that I am right, but I believe that this tribe live in Florida, and joined forces with the Spaniards in fighting against General Jackson just before the annexation of Florida. At any rate, this Rose grows all over the houses in the South below Maryland, and especially well in Florida. It is not unlike the rugosa Rose, although the petals of the Cherokee Rose are thicker and more satinlike.—F. A. S. [Rosa laevigata, a species found originally in China, but probably also a native of the Himalaya, is usually called the "Cherokee Rose." This name has apparently arisen from the specific name given to it by Donn of Rosa cherokeensis. It is semi-evergreen and not very hardy. Many other names have been given to it, including those of Camellia, camelliæfolia, hystris, nivea, sinica, ternata and triphylla. The Rose from the Southern United States to which our correspondent

refers is probably the Prairie Rose (*Rosa setigera*). We may add that the "Kew Hand List of Trees and Shrubs" gives *R. laevigata* as the Cherokee Rose. A description of it under the name of *R. sinica* is to be found in the *Botanical Magazine*, t. 2847.—ED.]

The Dawson Rose.—When we had many fewer rambling Roses than we now possess, the Dawson Rose was much more popular than now, as it was then a comparative novelty, and its claims are apt to be overlooked now among the multiplicity of new wichuraianas and other ramblers. The Dawson is a neat pillar or wall Rose, soon covering a pillar well, and giving plenty of its semi-double flowers, which are borne in good clusters on nice dark green foliage. These flowers are of a brilliant rosy pink. I observe that it is credited to Messrs. Paul and Son, and as being sent out in 1898, in some lists, but I think it is really of United States origin. It has been in my garden for a number of years, coming to me as a tiny rooted cutting from the United States. It does well here on its own roots.—S. ARNOTT, *Dumfries*.

Ceanothuses Under Glass.—The note on page 302, issue June 15, is a very timely one on the subject of forced shrubs for indoor decoration. Many

SIR ALEXANDER CROSS, BART.

kinds have beautiful foliage as well as flowers, and with due care a continuous display of blossom may be had from January until they come into flower in the open borders. I consider the note referred to as timely, because cultivators must procure or prepare their plants well ahead of the time that they require them to be in bloom. During the present summer plants in pots or tubs that need it must be shifted to larger ones or be top-dressed, and, furthermore, as suggested, plunged in ashes or ordinary garden soil. The Ceanothuses are charming as pot plants, the variety *C. dentatus*, having a half-bushy habit, being especially suitable. *Ceanothus Gloire de Versailles* must not be omitted; its long panicles of blossoms are most beautiful.—B.

Rosa gigantea.—Seeing the notice of this Rose in your issue, I would mention as regards its hardiness that the plant of mine you referred to on July 23, 1892, and again on June 2, 1900, was,

when I left Reigate last June, still growing some twenty feet to thirty feet up the west side of my house. It has, however, never shown any sign of bloom. I always noticed that it never began to make its first long shoots till after other Roses, like Crimson Rambler, had already finished making their long shoots. Naturally, in hard winters it got much cut. If grown under glass it doubtless gradually acclimatizes itself, as so many plants do which change their time of flowering under glass. My plant shows its hardiness, as it has survived, unprotected, for some twenty years.—J. R. DROOP.

Exhibiting Daffodils.—Concerning the much-discussed "faking"—"improvement" I would call it—of blooms for the show-bench, I submit it is a practice that should not be condemned. It is absolutely "above board"—there is no secret in it; it is open to everyone to indulge in who cares to take the trouble. Without a question certain blooms can thus be "improved." Then why not do so? No one, I presume, will gainsay that it is the duty of a flower at a show to look its best, and that it is the exhibitor's business to see that it does do so. *Débutantes* would not dream of appearing at a *Levéé* except in Court dress, and generally "looking their best." It is expected of them. So with the flowers. But there is another aspect of the matter. To penalise artistic "faking" is to penalise the "small" man and give a further advantage to the "big" man in exhibiting. To select sufficient "show" blooms from a big stock is comparatively simple. But for the small man to produce the requisite number of flowers from his limited stock good enough to compete with his big neighbour is a very different, and always difficult, matter. So often—and I speak from personal experience—one has perhaps but three or four blooms of a variety. Two perhaps are good, the others moderate or worse. Unless by "faking" one can make the bloom of moderate form passable, one must give up showing what is perhaps a good and telling variety, and suffer in points accordingly. "Faking" thus becomes a necessity for the small man, unless he is to be unduly handicapped by lack of money, and no true Daffodil-lover will wish mere "shekels" to be the main-spring of his delightful hobby.—A SMALL EXHIBITOR.

—I have followed this correspondence arising from the Rev. J. Jacob's originating article with interest, for the subject is an important one. Mr. Watts (page 226) apparently desires that "artistic arrangement" should be the determining factor of success rather than excellence of flower. But who shall decide what is "artistic"? No two people see alike. The task both of judges and exhibitors would decidedly not be enviable under such conditions. The latter would never know what particular style of "artistic arrangement" appealed to the judges. They would have no fixed point to work to. At present they have excellence of bloom as their criterion. Mr. Watts, however, appears to dislike the "fixed point" idea—he dislikes anything stereotyped; he would encourage individualism in exhibits, yet his alternative to existing methods, all said and done, is, on his own admission, only that of "follow my leader." I believe the public do not care a brass farthing for "artistic arrangement" at Daffodil shows. They do not pay their money to see artistically-arranged foliage, but they do to see the blooms; and I maintain that the existing customary method of setting up not only shows the merits (or otherwise) of the individual flower to the greatest advantage, but it also greatly simplifies the task of judging.—A. C. C. R.

Enquiry.—Will some experienced fellow-gardener advise me how to flower *Ourisia coccinea*? It grows well in my rockery (North Riding, Yorks), planted at the water edge, some in partial shade, some in full sun, but it bears very few blooms.—**DICHROMA.**

Suggestion for a Small Rock Garden.—I enclose a photograph showing how I transformed a steep bank in front of my house into a small rock garden, which may be of sufficient interest to justify its reproduction in your paper.—**GEORGE LYON, Cairnryan, Howick.**

Rosa Moyesii.—Some three years since I purchased a plant of *Rosa Moyesii*, and for the first two years it occupied a position facing south and west, getting full sun after noon. There it produced only half-a-dozen blooms each season and made but little growth, and I feared it was a bad doer and sparse flowerer. Last autumn I transplanted it in a border with an east-south-east aspect. This spring the plant has been a sheet of flower, producing some one hundred and fifty of its beautiful crimson blossoms, evoking the admiration of all who have seen it. The plant is now sending up basal shoots some five feet high, and I am hoping that next spring it will do even better than this. I may add that I give it no protection in the winter, and there is no evergreen hardier than this. I think if this lovely Rose were better known, many more would be grown than is now the case. There is no Rose that I am acquainted with about the colour of the flowers of which there is so much difference of opinion, but, however it may be described, there is no gainsaying its special beauty.—**B.**

A Useful Lupine (*Lupinus polyphyllus* Moerheimi).—*Lupinus polyphyllus* and its varieties, so long esteemed as border plants of the first merit, have recently attracted increased attention by reason of the introduction of the pink-coloured forms, of which the most distinct is *Moerheimi*. Unlike its immediate forerunner, *polyphyllus roseus*, the first-named maintains its freshness and bright colour almost up to the moment the flowers fade. Never by any chance have I noted the flowers of *Moerheimi* exhibit the muddy purple colour that so greatly detracts from the value of *roseus* as a border plant. *Lupinus Moerheimi* forms a dense bushy plant of beautiful leafage; the main flower-stems are borne on the terminal points of the shoots, and are succeeded by laterals, which also flower and continue the display from May till July. It is the dwarfest of all the forms of *polyphyllus*, growing to a height of 3 feet. Its tapering, slender spikes of bright pink and white flowers proclaim it a plant of sterling merit and one of the most distinct of recent introductions.—**THOMAS SMITH.**

A Beautiful Speedwell (*Veronica filifolia*).—Admirers of rock plants would have observed the charming *Veronica filifolia* in some of the exhibits of alpinists at the great Chelsea Show, but it is only those who can see really good plants who know its full beauty. It is a plant familiar to the writer, who once obtained it from the garden of a great Continental amateur a good many years ago. His own plant was lost through a combination of unfortunate circumstances, but while it lasted it was a source of great pleasure with its dainty leaves and its still more dainty light blue flowers. There is something almost lace-like in its appearance. The rock garden is the favourite place for this *Speedwell*; but I was greatly struck with its beauty as a wall plant on seeing it at Monreith, Wigtownshire, the other day, where Sir Herbert Maxwell has such a fine collection of alpinists

growing on a terrace retaining wall. Here *Veronica filifolia* was remarkably fine. In perfect health, of good size and full of flower, it was the *beau-ideal* of a wall garden plant. It is hardly likely that it would be nearly so fine without a good body of soil behind it, but with such conditions and fully open to the light it formed a grand sight that could hardly be surpassed.

Coronilla montana.—This hardy rock plant is not, apparently, a popular one, being probably less frequently offered by nurserymen than its merits would warrant. It is a capital rock garden plant, making good sheets of pleasing leaves and giving a good display of its bright yellow flower-heads. I have never met with it so fine as on the wall garden of Sir Herbert Maxwell at Monreith, Wigtownshire. There a large plant on the retaining wall of a terrace at the garden front was in full bloom the first week of June, and was really magnificent. The mass of flower was of the brightest golden colour, casting into the shade the

THE FLOWER GARDEN.

THE HERBACEOUS BORDER.

THESE borders are now full of many beautiful flowering subjects. Constant attention should be afforded the plants. To maintain a continuous supply of healthy growth and abundance of flowers it is necessary to note and carefully minister to the wants of each individual subject. In large mixed borders, gross feeders, such as Delphiniums, Hollyhocks, Dahlias, Asters and many others, are often in need of copious supplies of liquid manure-water. Other subjects growing in light soil may require a mulch of decayed manure. The question of staking plants, so as to prevent the growths being damaged or the flowers broken off by wind, demands a good deal of careful consideration. Strong-growing plants must be provided with

ROCKWORK AND STEPS IN A READER'S GARDEN.

other yellow flowers in its vicinity, and especially bright in the sunshine. With the writer it does not flower so freely, and he attributes this to the more sunny position at Monreith, the greater heat from the wall, and possibly to the fact that there are a good many broken shells among the soil in which the *Coronilla* is planted. On the ordinary rockery it is seldom so fine as at Monreith.—**S. ARNOTT.**

strong supports. At the same time, the object should be to make these supports as inconspicuous as possible. A timely thinning of the shoots of many plants is perhaps an operation which many amateurs fail in carrying out. It is, however, the best way to obtain good results with many of the subjects which throw up numerous shoots from their base, such as Asters, Solidagos, Helianthus and many others. Weeds should never be allowed to grow in the borders, and the Dutch hoe should be plied frequently between the plants. Water should be applied copiously in the absence of rain. Notes should be taken of the habits of any recently-acquired plants. Further notes also on the border as a whole, or any particular plant which does not seem happy in its surroundings, will prove most useful later on when a general rearrangement of the plants may be carried out. One of the most difficult problems of the herbaceous border is that often experienced of keeping up a continual display with no unsightly gaps. Much may be done by filling in with summer

flowering subjects grown on in pots for this purpose. The use of annuals, either sowing the seed in the border or introducing young plants, will in many cases prove successful. It is wise to have a full scheme prepared and provided for in advance. The practice of providing borders of plants flowering at different seasons has much to recommend it; but many gardens, both large and small, possess borders which their owners desire should be made as bright and interesting for as long a period as possible. Dead flowers should be removed, and everything made tidy and neat. The hardy plants of our gardens are real subjects of beauty, and, if they are carefully tended, are capable of producing effects which will repay fully all the care bestowed upon them. Many new plants are being added to the nursery lists, and a perusal of these lists will be a source of pleasure and profit to the ardent cultivator.

C. RUSE.

Lambay Island, County Dublin.

SEASONABLE NOTES ON AURICULAS.

Fresh Air.—If there is one thing more than another that the show and alpine Auriculas appreciate at all seasons of the year it is fresh air, and the tyro in their cultivation is warned that unless he is prepared to afford it in absolutely unlimited quantities, he must not expect to attain the most beautiful results. In the winter a certain amount of discretion has obviously to be exercised in the admission of air either to a house or a frame, but in the summer let the plants have all they can get and they will be the better for it. When torrential rains are falling one would not, of course, have the light right off the frame, because the soil in the pots might conceivably be so sodden as to turn sour and thus cause serious injury, but even then the light must not be closed down, and whenever the conditions are favourable it should be open.

Cleanliness.—Notwithstanding the indisputable fact that Auriculas are among the best of all plants for culture in cold greenhouses and frames in town gardens where the atmospheric conditions, even in the most favourable of circumstances, are never too pure, there are no plants which demand more scrupulous cleanliness. The soil, the crocks, the pots, the surroundings in the structure and the plants themselves must all be spotlessly clear if excellent health, which spells satisfactory progress, is to be maintained. The grower must, therefore, spare no pains which will go to ensure the desirable condition, or he will soon see signs of deterioration in the appearance of his cherished plants.

Sickly Plants.—The careful cultivator will look over all his collection at least once a day, and if the time can be spared he will do it twice; but at frequent intervals, in no case fewer than

once a week in the summer-time, he will subject them to a keen inspection, so that he may not fail to detect a plant that is on the sickly side directly the indications are visible. The trouble may be due to thrips, red spider, the root aphid, or the stem-boring maggot, but whatever it is, instant suppression must be the order of the place. In previous notes suggestions have been made as to the best steps to take in case either of these conditions should occur, and readers who are not familiar with the management of the plants are advised to refer back and diligently study the articles.

Sunshine or Shade.—Broadly speaking, the greater majority of plants grown in British gardens

points of view it is perfectly satisfactory to do so, but they are strongly urged to devote more than the ordinary care and attention to the plants for the first two or three weeks. The precise conditions of management differ slightly in every garden, and the changed surroundings may bring an element of trouble. There is not, as a rule, anything to worry about, but it pays over and over again to be watchful as a preventive of potential disappointment.

Seed-Sowing.—It has been said in earlier articles that the seeds now developing will become ripe at some time during July, and the grower will shortly have to decide whether he will sow immediately or defer the operation until the spring; there must be no half measures in this matter. Personally, I prefer sowing directly the seeds are ready, as I find that germination is more regular and the youngsters grow forward rather stronger; but those who do not find it convenient need not anticipate that the seeds will lose in vitality or that they will not secure eventual satisfaction. It is a matter of fancy and convenience when the work should be done. F. R.

ST. BAVO ANEMONES. A NEW RACE AFTER THE FULGENS TYPE.

revel in all the sunshine which our climate affords; but this is not the case with Auriculas. During the hot summer months it is imperative that the frame shall be given a northerly aspect, as the rays of the sun, even though there be some shade, will bring in their train troubles which the cultivator will experience difficulty in overcoming. The sunshine of winter is a different thing. Then the power is much less, and the plants will not thrive for long unless they have all the light that it is possible to afford them; but now, if it has not already been done, turn to the north.

Importations.—Amateurs commonly import plants during the summer-time, and from many

grandiflora—that strikingly handsome green-ringed, wide-petalled, Grecian type of Windflower—was observed to vary somewhat in colour and to incline to a much paler shade than the ordinary. It was marked and seed saved and sown. In the third and fourth generations further breaks appeared, and these have been added to by each successive sowing until to-day we have the new race in almost all the colours of the rainbow. I heard from headquarters two or three weeks ago that the firm had decided to name them the St. Bavo Anemones, as they have begun life within sight of the "great church" of the town whose titular saint is St. Bavo, JOSEPH JACOB.

ST. BAVO ANEMONES.

DURING my visit to Haarlem this spring, it was my good fortune to go to Mr. van Tubergen's nursery on a sunny morning when the whole of these glorious Anemones were wide open in all their brilliance and splendour. There was a wide range of colour, from the richest reds to pale creams, almost white, and innumerable shades of purples and blues. Growing close to them were a few beds of M. Emile Gadaecan's stellata type, but these in comparison with the St. Bavo were dull and insipid. This new race is distinguished by its bright colours, the width of its petals, and the great dark boss in the centre of each bloom which proclaims its relationship with the fulgens type. Its origin is interesting and suggestive. It is another example to add to the long list of horticultural triumphs which have had their beginning in some slight difference of colour or form which the observant eye has noted, and which patient care and selection have perfected. About ten years ago a solitary plant of *A. fulgens annulata*

THE ROSE GARDEN.

BEAUTIFUL NEW POLYANTHA ROSES.

SOME charming novelties are appearing in this very useful section, and one of special beauty and charm is

Tip-Top, a most lovely blending of carmine on the inside of the petals, and buttercup yellow on the back of the petals. When it was shown to visitors recently, they exclaimed, "Why, it is a Baby Juliet!" so this will give one an idea of its novel colouring.

Mieze is another charming kind, as perfect in form as Cecile Brunner, but of quite amber apricot tints, with shades of pink and orange, and the buds before they open are almost red. An altogether charming sort.

Mrs. Taft will supplant Mme. N. Levassieur. It is a lovely soft rosy crimson colour; nice bushy habit.

White Cecile Brunner is a gem. Some of its flowers are pure white, others sulphur or chamois. It possesses all the exquisite shape of the well-known Cecile Brunner.

Jeanne d'Arc, a most free-flowering variety, with fine bunches of tiny milk white blooms. It is practically always in flower, and would make a fine plant for bordering with Jessie as a background.

Cyclope in form is like a double Primrose; its colour is deep violet purple; dark foliage.

Bettelstudent has single blooms, produced in clusters. They are deep carmine in colour, with white centre. It is a very free and effective kind.

No one should miss an opportunity of planting the larger-flowered section, of which there are now some beautiful things. They come very near to the Hybrid Teas, but as decorative subjects they are fine.

Gruss an Aachen has reddish orange buds, opening light pink. A most charming Rose of free growth.

Yvonne Rabier is a glorious pure white, one of the most decorative Roses we have had for a long time. Its flowers are quite large, almost like Aimée Vibert, but produced in big clusters, erect in growth and dense in floriferousness.

Maman Turbat is also fine, a lovely satiny pink as seen under glass, also with huge clusters produced in erect form.

These would be fit companions to the older Mosella and Clothilde Soupert, Roses not seen much now, but very lovely.

A CHARMING SINGLE ROSE.

ONE of the loveliest objects in my garden in May and early June was a fine plant of *Rosa sinica* Anemone running over old tree stumps set up for the purpose. At first sight visitors took it to be a very early-flowering Clematis, but on closer inspection, of course, they were soon undeceived. Apart from the beauty of its handsome rose pink blooms, which are often 5 inches across, the olive green, shining foliage is really beautiful, and after the short flowering season the plant remains an object of

much beauty for its foliage. We have now still another beautiful addition in Mrs. A. Kingsmill, a seedling from *R. sinica* Anemone, which is of more bushy form, and what is indeed very valuable, it is autumn-flowering. It is the second cross from a species, which is proof, if any were needed, that most remarkable results may follow the hybridising of the various lovely species with our modern ever-blooming Roses.

ROSE FRANCIS CHARTERIS SETON.

OF the many grand emanations from Waltham Cross, the above-named will, I think, prove one of the best. It has been glorious with me under glass, and for this purpose alone I can strongly recommend it. The colour is such a lovely warm cherry pink. Then, the build of the bloom is such as will commend it to exhibitors—high-centred, with tapering point in the half-open stage, fine outer petals, pointed as in La France, and with great

WISLEY GARDENS IN JUNE.

THIS is perhaps the most interesting time of the whole year at Wisley, for during the latter days of June the Roses, Pæonies, Delphiniums, the spacious water garden, the woodland and wild garden are seen in the height of perfection. From their natural surroundings, isolated position and congenial soil, the Royal Horticultural Society's gardens at Wisley are most pleasantly situated. Moreover, the gardens are bathed in the pure air for which the Surrey Hills are noted. Hence it is that vegetation of all kinds, from large coniferous trees to the daintiest of alpines, flourishes amazingly at Wisley, while many of the same plants cannot be persuaded to eke out an existence a few miles nearer London.

A CORNER OF THE WATER GARDEN AT WISLEY, SHOWING IRIS KÄMPFERI NEAR THE WATER'S EDGE.

fulness, which will make it a good "stayer" on a hot day. The growth is good and the flowers are borne upright, which is a great desideratum for a forcing Rose, and also for garden culture. Then, too, its fragrance is of that nature we used to love so much in the old Hybrid Perpetuals. Raisers would do well if they employed the Hybrid Perpetuals as seed parents more than they do; far better than to rely upon crossing Hybrid Teas with the same tribe. We should then not only obtain fragrance and size, but also some of the richer shades of colour we want so much in our present-day Roses. Another Rose that Messrs. William Paul and Son distributed last year, namely, Lady Downe, is one likely to be heard much of. This, too, is deliciously sweet, and has a fine colour, almost like Mme. Ravary in its tint, with splendid stiff flower-stems.

By reason of the distance between Wisley and any railway station (the gardens are about five miles from Weybridge Station), comparatively few visitors find their way to the gardens, but those who do so are more than repaid for their efforts. The impressions of a recent visit, together with the illustrations of these notable gardens, will, no doubt, be perused with interest by those who have not the time at their disposal to make a personal visit.

Roses at Wisley.—A long Rose walk, with dwarf Roses in the border and ramblers in the background, is now in full bloom. In the very comprehensive collection of bush Roses it is gratifying to note that such old favourites as Caroline Testout, Mme. Hoste, Mrs. J. Laing and La France still hold their own in competition with their many new rivals. The ramblers are trained over upright

rustic poles. Three stout poles, tied in at the top to form a tripod, are placed to each variety. We have on previous occasions drawn attention to this mode of training Roses, and it is certainly one of the simplest and most effective means of growing ramblers. The plants in question are yielding a profusion of bloom, and the rustic work in most instances is completely hidden from view. Three of the best varieties grown in this way are Una (white), Léontine Gervaise (apricot) and Jules Levacher (pink). A climbing plant in the Rose walk, likewise growing over rustic poles, has the misfortune to bear the name of *Polygonum baldschuanicum*. It is a rampant climber from Bokhara, and produces masses of rose-tinted white flowers in the wildest profusion. Roses do remarkably well in this delightful garden, and this is a little surprising, as the soil is of a light and somewhat leaty nature. Weeping standards are a great success, and constitute a most pleasing feature. On this page we give an illustration of the variety François Guillot, grafted about four feet from the ground, and clothed with bloom down to the soil-level. Other promising varieties growing in a similar manner are Elise Robichon, Alexandre Pirault and Joseph Billard. In view of the admirable way in which Roses grow in different parts of the gardens, it is to be hoped that in the near future the society will establish a model Rose garden at Wisley. This proposal is warmly supported by members of the society, and we wish all possible success to this praiseworthy scheme.

The Wild Garden.—The real charm of these noted gardens is found in the wild garden, which is quite hidden by trees and shrubby vegetation from the outer world. Here at every turn one meets with something good to see, and certainly worthy of study and emulation. It was this garden that its late owner, Mr. G. F. Wilson, V.M.H., loved so well. The visitor is led by way of crude paths and stepping-stones here and there between luxuriantly-growing Bamboos and Rhododendrons, the latter flowering exceptionally well this year. *Rhododendron Wilsonii*, with small Azalea-like pink flowers, is just now a perfect mass of bloom. *Kalmias*, which are also peat-loving plants, are now flowering with great freedom. Some remarkably good clumps of the New Zealand Flax (*Phormium tenax*), this year producing seed in quantity, were also noted, while in the dense shade of overhanging trees many kinds of Lilies are seen. The Giant Lily (*Lilium giganteum*) and its colony of seedlings look particularly happy amid their wild surroundings. In passing what might at first sight be regarded as a neglected ditch, one observes healthy clumps of *Primula japonica*, Wood Lilies, *Trollius* and other moisture-loving plants in a congenial home, while a grand clump of *Shortia*

galacifolia near by did not escape notice. British Orchids abound on all sides in this delightful garden. One feature of exceptional interest is the naturalising of *Dictamnus albus* and *D. purpureus* in grass. The spicy-scented flowers are now seen at their best, and the illustration gives a good idea of the freedom with which *Dictamnus* blooms under these conditions.

Plants by the Water-side.—The rich and varied hues of the Japanese Iris (*I. Kämpferi*) are now

Saxifrages and Rock Roses give one an idea of the beauty this garden will attain in the course of time. An admirably-constructed dripping well is one of the chief features, while the moraine garden is sure to appeal to all lovers of alpine gardening. The latter is already planted with some of the daintiest of alpines, which are notoriously the most difficult to cultivate.

A large field of Pæonies is now gay with blossom. The new Imperial section, with outer shell-like guard petals surrounding a cluster of golden petaloids, are well represented in the collection. There are many promising varieties of Delphiniums in an extensive trial. Some have grown with most astonishing vigour, attaining a height of 15 feet. If the competition were for height, there would be many worthy competitors. As this trial has since been judged, the varieties will be commented upon in an early issue.

The gardens consist of about sixty acres of land, and not only are they noted for their beauty, but are also worthy of note from the point of utility. Several acres of fruit trees have been planted, and an outdoor vineyard has been started as an experiment. Trials of vegetables, as well as of flowers, are continually in progress, and an extensive range of glass-houses, including orchard-house, vinery, stove, Orchid-house and propagating-pits, enable all departments of horticulture to be represented.

KITCHEN GARDEN.

SEASONABLE NOTES ON VEGETABLES.

Asparagus - Beds.—With the end of the present month all cutting from beds of this delicious vegetable must cease for the year. It is quite certain that many amateurs will never allow themselves to be persuaded of the immense importance of this ride, and the result is that their beds soon begin to lose vigour, and that, of course, spells lack of productiveness. If a definite principle is laid down to

retain the first and second shoots which spring through the surface each season, and that cutting shall stop at the end of June, it is not difficult so to manage the beds that they continue profitable for considerably more than a generation. The complete cessation of cutting must not, however, be accepted as meaning that no further attention need be given to the plants; as a matter of fact, this is the most important period of progress, because the foundation of next season's success is laid now. See that the soil in the beds never becomes dry; and should an opportunity arise to follow watering with a heavy soaking or two of good liquid manure, by all means seize it. In order to make sure that all food in the ground goes to the benefit of the plants, weeds must be rigidly suppressed, and in no circumstances whatever must a single shoot be cut out. In exposed

A WEEPING STANDARD OF ROSE FRANCOIS GUILLOT IN THE ROYAL HORTICULTURAL SOCIETY'S GARDENS.

showing to the best advantage by the water-side, and Water Lilies, including *W. E. Gladstone* (large ivory white), *Froehelii* (deep red), *Mariacea chromatella* (yellow), *M. carnea* (blush pink), *Robinsonii* (rosy crimson) and *ellisiana* (rosy red), are all to be seen in the height of perfection. Our illustration on page 329 depicts a corner of the water garden, in which *Iris Kämpferi* and *Nymphaeas* may be seen in flower, while the background comprises Royal Ferns (*Osmunda regalis*) and the noble-looking *Gunnera* with large, spreading leaves. In another direction an immense rock garden has recently been constructed. It is situated on high, sloping ground, and, when the alps are a little better established, will doubtless be reckoned among the finest rock gardens in the country. The result of recent planting is already apparent, and the flowering patches of Sea Pinks,

positions there is liability of damage by winds, and steps must be taken to prevent it. Stout supports at intervals, with strong string stretched between, answer admirably.

Green Vegetables.—Throughout July all favourable chances should be grasped to plant the green vegetables which will prove of such immense value during the autumn, winter and spring months. The desirability of carrying out this work in showery weather cannot be doubted; but it is not wise to wait too long for the rain, which may not come for weeks at a stretch, as witness the conditions that prevailed last summer. When ground falls vacant which it is intended to occupy with these plants, prepare it immediately, allow it to lie vacant for a time to sweeten, and then get the occupants into their places as soon as can be managed. To put the roots into soil that is as dry as dust is a serious error, which the experienced cultivator avoids by heavy watering the evening before planting is to be carried out. If water cannot be afforded for the whole quarter, soak the particular places where the plants are to go. This prevents in large measure the severe check to advancement that flagging must necessarily inflict.

Celery Fly.—Careful growers have been incessantly on the watch for this pest since the plants

were first moved from the seed-boxes to the nursery beds, and it is most important that there shall be no relaxation of vigilance. It is folly to wait until the fly has pierced the leaves and deposited the egg, as one can then do nothing that is of substantial good. Instead, proceed with preventive measures, and comparatively little harm will ensue. Frequent dustings with a mixture of old soot and wood-ashes are excellent if done when the leaves are damp; but the utmost care must be exercised not to let the stuff get into the hearts, or the colour of the stems will be completely ruined.

Spring Cabbages.—The correct time for sowing seeds of Cabbages to yield most welcome produce in the early months of the spring varies with every district, and in some slight degree with every season. I am a staunch advocate of two sowings, the first on the accepted best date, and the second fifteen days or so later. This practically precludes failure due to the plants growing so freely in an open autumn that they become too "proud" to stand the variable weather of the winter. As we all sow too thickly, the double expedient need not involve greater outlay; simply divide the usual quantity into two and go ahead.

Outdoor Tomatoes.—These will demand regular attention from now onwards until the whole of

the fruits have been gathered for use. In practically all instances they will have settled down admirably, and it is important that the soil shall never be allowed to become as dry as dust; on the other hand, it is fatal to make it sodden. Each shoot that is seen springing in the leaf-axils must be rubbed out before it is half an inch in length, as concentration to one stem is essential to the finest results. Malformed flowers should be picked out directly they are seen. H. J.

LATE DWARF FRENCH BEANS.

A LATE sowing—indeed, several sowings—from the end of June well into August will provide a welcome supply at a time of year when choice vegetables are getting somewhat scarce. Of late years the Dwarf or Kidney Bean has found less favour for home supplies, on account of the taller Climbing French being largely grown; but this should not be so when vegetables of the best quality are in constant demand, as the Dwarf French is most valuable if the produce is well grown. I am aware that for market purposes it is less popular than the Runner, but for home supplies we should not study market procedure, but endeavour to get the best possible quality.

It is useless to grow this vegetable in poor soil, and heavy clay land well repays liberal additions

A FINE COLONY OF DICTAMNUS NATURALISED IN GRASS IN THE WISLEY GARDENS.

of lighter materials, such as burnt garden refuse, old leaf-soil, or spent manure, and if this cannot be incorporated with the soil, it is a good plan to place a liberal amount in each trench previous to sowing. In poor or heavy land I would advise deep drills or shallow trenches, as, grown thus, the necessary waterings and feeding to obtain good results in a dry season are readily given. In such land I have found spent Mushroom-manure an invaluable aid, as it not only lightens the soil but retains the moisture, and as the Dwarf Bean is a crop quickly cleared, unless food and moisture are given the results are poor. And this opens out another question: Why grow the Dwarf Bean when the Runner can be grown with less labour? But as a distinct second-course vegetable the Runner is less useful. The Dwarf in this respect cannot be equalled, and when well grown is delicious. By the term "well grown" I do not mean large pods, but small ones. If these are gathered regularly so that the seeds have not matured, the quality will be much superior and the pods will require very little preparation for the table.

It is a good plan to gather the pods and either place the stalk end in water or damp the pods and lay them in a cool place till required for use. A word should be given as to the cooking. Often the pods are allowed to get too old, but if they are young there is no necessity for the slicing and paring. Cooked whole they are delicious, and the flavour is then much better than when served, as is often done, with the seeds well advanced and the pods tough and flavourless.

Those who have not grown the Dwarf French for a late supply will be surprised at the good results obtained by late crops. It should be pointed out that in the culture, say, for August supplies, a cooler site or border should be selected, and thin sowing is strongly advised; failing this, thin freely so that each plant can have room to develop. It is well in dry weather to soak the seeds for some hours to assist them to germinate more quickly, also to well water the drills or trenches.

For a quick crop the smaller-podding varieties should be chosen, and for a longer supply those of the Canadian Wonder type or Magnum Bonum. For cooking whole, the Stringless Beans are a splendid vegetable. In this section there are numerous varieties, such as Holborn Wonder, Canadian Glory, Bountiful and others. The Golden Waxpod or Butter Beans make a splendid addition to the list of late summer vegetables. This variety is of great value when well grown. Such kinds as the one named *o*: the Centenary, Golden-podded Mont d'Or and Dwarf are excellent when cooked whole as advised above.

G. WYTHES.

TREES AND SHRUBS.

RHODODENDRON VASEYI.

THIS is a comparatively little-known species, a native of Carolina. As a garden plant it is more often referred to as an Azalea, being deciduous and flowering in advance of the leaves. The individual blooms are about an inch across. The shade of colour varies considerably in a batch of seedlings, from white, pale pink or rose to occasionally a rich deep rose. The flowering season is the end of April and early in May. Like most of the

A FLOWERING SPRAY OF RHODODENDRON VASEYI, A LITTLE-KNOWN SPECIES FROM CAROLINA.

Azaleas, this one flowers freely in a small state some 15 inches to 18 inches in height, though, according to "Garden and Forest," in its native habitat the plants grow to a height of 15 feet or more. In addition to propagation by seeds, cuttings made of the half-matured growths towards the end of July will root in a propagating-frame with a slight bottom-heat.

CLEMATIS FLAMMULA.

The delightful fragrance of this Clematis has been likened to that of the Hawthorn. It is not a tall grower; 6 feet to 8 feet appears to be about the

average height. The flowers are creamy white and about an inch across. During July and August the plants are clothed with axillary and terminal panicles of blossoms, these giving place in September and October to the heads of fruits with the familiar feathery tails. *C. Flammula*, which has been named the Virgin's Bower, is fairly well known in gardens, but not nearly so much as its merits deserve. When covering trellis-work or clothing an arbour near a dwelling-house, the air all round is perfumed with its fragrance when in flower, the beauty of blossom and seed lasting for fully four months.

It is a native of Central and Southern Europe, and has been known in gardens for more than three hundred years. For small vases the flowers may be employed effectively for cut-flower decoration, while in large vases it may be used in association with other flowers as the better-known *Gypsophila* is employed. One disadvantage is that the blossoms do not last as long as the *Gypsophila*, but they have an advantage over the last-named in being fragrant. *C. Flammula* requires very little attention in respect of pruning. In spring, when the growth-buds show prominently in the axils of the leaves, the old flowering growths should be removed down to these points. A. O.

A CHINESE BARBERRY.

(*BERBERIS DICTYOPHYLLA ALBICAULIS*.)

BERBERIS DICTYOPHYLLA is a showy Barberry from China, which appears to have been first brought to notice by Franchet, who found it among the specimens collected by R. P. Farges. It has been in cultivation long enough to prove that it is likely to make a good garden plant, for it grows at least 4 feet high, is of good habit, and bears showy yellow flowers and conspicuous scarlet fruit. Moreover, the under sides of the leaves are glaucous, while the stems also have a glaucous hue. The variety *albicaulis*, however, is of more recent introduction. It appears to be of looser habit than the type, and the peculiarity which appeals most forcibly to the gardener who is on the look-out for ornamental garden plants is the dense glaucous covering which appears on the stems. The under sides of the leaves are also whiter than those of the type. As it becomes better known, it ought to form an interesting addition to the list of coloured-stemmed shrubs. From this standpoint it is certainly the most conspicuous of the numerous varieties of *Berberis*. As is the case with other coloured-stemmed plants, the colour is most highly developed on vigorous branches; hence the necessity for planting it in fairly good soil. In association with coloured-stemmed Willows, Dogwoods and Brambles it is fine for winter effect. W. D.

GARDENING FOR BEGINNERS.

THE SUMMER PROPAGATION OF ROSES FROM CUTTINGS.

1.—ROSE SHOOTS THAT HAVE PRODUCED FLOWERS MAKE THE BEST CUTTINGS.

IT often happens that the beginner in gardening matters is desirous of increasing his stock of Roses, but has no clear idea as to how the work should be done, and the following notes have been prepared for his guidance.

Rose cuttings may be taken at two different periods, namely, when the young wood is just becoming firm, about July, and when the wood is thoroughly ripe and the leaves have fallen. Cuttings of the latter kind are prepared during late autumn and early winter, and such cuttings are usually made from 9 inches to 12 inches in length and inserted in the open ground, all but the upper 3 inches of each cutting being buried in the ground. Cuttings made in summer, however, are treated very differently, for they are rarely made more than 4 inches or 5 inches in length, and are usually rooted in a frame or propagating-case, although good results may be obtained by inserting them under a hand-light out of doors. All kinds of Roses are not suitable for summer propagation. Generally speaking, those kinds which form roots quickly, such as the various Teas, Hybrid Teas, Ramblers, the less spiny Hybrid Perpetuals and the China Roses, may be increased

3.—ON THE LEFT, ROSE CUTTINGS MADE WITH TWO EYES ONLY; THESE ROOT READILY IN HOTBEDS, NORMAL CUTTINGS ON THE RIGHT.

during summer, whereas kinds which have their branches thickly beset with spines, such as the Rugosa hybrids, Scotch Roses and Moss Roses do not root readily.

The most suitable wood for cuttings is that which is becoming rather firm, such as short, flowerless shoots, branches which have flowered (see Fig. 1), or the lower parts of the long growths of ramblers which have been formed during the present year. Soft, pithy shoots are worthless for cuttings, and those of moderate growth are usually more satisfactory than very vigorous branches. Cuttings may contain from four to five buds, although if wood is scarce it is not necessary to allow each cutting more than two buds, one to form roots

and the other to form a shoot. When making cuttings, cut the branch through horizontally, just below a bud for the base of the cutting, the upper part being made with a slanting cut just above a bud. Remove the lower leaf or leaves, and if the upper leaves are very large, reduce the size. Do not remove any of the buds, for it is a good plan to encourage growths from beneath the soil in the case of Roses growing upon their own roots. From the time the shoots are removed from the bushes until the cuttings are inserted, they must never be allowed to become dry. When collecting cuttings it is a good plan to have a basket partly filled with damp moss, in which the branches, and afterwards the cuttings, can be laid and covered over until ready for insertion.

Compost.—The most suitable compost for Rose cuttings is made up of three parts good, sweet loam, one part leaf-mould and one part silver sand. Whether used in pots or in beds, it must be made moderately firm, and the upper inch should have been passed through a sieve with a half-inch mesh. Over the soil a thin layer of silver sand may be placed with advantage. When the cuttings are placed in pots, the sizes known as

5-inch and 6-inch are the handiest sizes to use (see Fig. 2). As a rule, the cuttings nearest the sides of the pots root a little in advance of those placed in the centre, a fact to be borne in mind when inserting cuttings. The depth to which cuttings are buried in the soil deserves consideration, for on this a great deal depends as to whether they will root well or not. As a guide it may be added that the regulation depth for this class of cutting is that one-third of the length should be buried in the soil. When heat can be employed, the cuttings may be expected to root in from

two to three weeks' time. Where a propagating house exists, heat is always available; but such a structure is not essential to success, for quite as good results can be obtained by plunging the cutting-pots in an ordinary hotbed made of manure, such as is often employed for Cucumbers. In fact, where large quantities of Roses are required in some American nurseries, the habit obtains of making up hotbeds, covering them with soil, and dibbling the cuttings in 1 inch apart each way. The cuttings are made with two eyes each (see Fig. 3), one for rooting and one for growing. The frames are kept very moist and close, but shaded from bright sun, exposure to fierce sunlight for ten or fifteen minutes being sufficient to ram the whole bed by scalding. In from ten to fourteen days the majority of the cuttings inserted in this way have rooted, when they are gradually hardened off and potted. The pots should be plunged in Cocoanut fibre to help to keep the soil moist, and the atmosphere of the frame or case must be kept moist and close, shading being

2.—A POT OF ROSE CUTTINGS. THESE MAY BE EXPECTED TO ROOT IN FROM TWO TO THREE WEEKS' TIME.

employed during periods of bright sunshine. In the absence of artificial heat, place the cuttings in a close, cold frame or under a hand-light, where they may be expected to root, but not in such a short space of time as when heat is employed. The young plants may either be potted singly and kept until the following spring to be planted out, or they may be hardened off and planted out in autumn. The former is the better method for the more tender kinds.

An item to which the propagator should pay special attention is the probability of the shoots of the young plants being attacked by green fly, even before they leave the propagating-case. At the first sign of fly the leaves of the young plants should be allowed to dry, and the house must then be fumigated with tobacco or with a nicotine preparation, fumigation being repeated at intervals if necessary.

GARDENING OF THE WEEK.

FOR SOUTHERN GARDENS.

Plants Under Glass.

Bamboos.—These, when grown in pots or tubs, make splendid material for furnishing the greenhouse or conservatory, and are also well adapted for indoors. For this purpose select those which possess the most graceful habit, and, of course, the less hardy ones may also be included, such as *Arundinaria falcata*, *A. Falconeri*, *A. anceps* and *A. gracilis*. Now that the young growths are pushing up freely, see that the plants do not suffer at the roots for the want of water, and stimulants at intervals will prove of assistance.

Chrysanthemums.—The plants for producing large blooms that were potted into their flowering pots some three weeks ago are now growing away nicely and must be secured against wind. An excellent method much in vogue is to stand a row of plants on a board beside the garden walk, and secure them to cord or wire stretched to stout stakes at intervals. If the weather is warm and dry, syringe the plants overhead twice daily. Before the plants make too much growth, insert the sticks that are to remain, choosing them as straight as possible, strong, and at the same time neat.

Pot Roses.—The plants that have done duty for inside supplies should be stood out of doors and allowed to mature their growths. See that the plants are kept supplied with water and nourishment, and keep the foliage in a healthy condition. The repotting I prefer to carry out in the late autumn.

Manure-Water.—As many plants are now needing a good stimulant, an excellent way of producing the same is to obtain some fresh cow-manure and mix it with an equal quantity of soot, adding the latter gradually until not a dry particle is left. Place in a strong, porous bag, secure the mouth, and suspend it in a tub of water. Dilute as necessary before using. Artificial manure may be given by sprinkling it on the surface of the pots, or taking sufficient for the time and puddling it with a little water, and then putting sufficient in the can to colour the water. Never apply either of the foregoing when the plants are dry, and only when they are growing and rooting freely.

The Kitchen Garden.

General Work.—The bulk of the work now to be done in the kitchen garden will consist of keeping the crops free from weeds, and whenever the surface is dry enough, ply the Dutch hoe as frequently as possible. Any vacant spaces that will accommodate a catch-crop, such as Lettuce, should be taken advantage of. All crops as they pass should not be allowed to occupy good ground, but be cleared off and followed as quickly as possible with another crop. Watering, in the event of dry weather, should be done as thoroughly as possible, and Cauliflowers and rows of Peas will greatly benefit by applications of farmyard or liquid sewage manure.

Spinach.—Make a sowing of this at the first opportunity for picking during the winter months. By sowing fairly early a good plant is ensured. Treat the ground liberally where it is to stand.

Shallots.—These will soon be ripe, and when ready lift the bulbs and lay them out in a sunny, dry position for a day or two before putting away in a cool, dry shed. Sort over and reserve sufficient of the smallest for planting next year.

Flower Garden.

Heuchera sanguinea.—A fine patch of this is one of the most useful plants we have now in the flower garden. The graceful spikes are admirably adapted for associating with other flowers, and are most useful for table decoration. To maintain a good supply, sow a little seed each year about this season in a box and allow it to germinate in a cold frame. When large enough, transfer the seedlings to boxes, where they may remain during the winter.

Border Carnations.—Keep the hoe going between the plants, and in showery weather give a dusting of soot between them. Attend to the tying of the flower-spikes as they lengthen.

Perennials.—The present is a good time for sowing any of these for the borders at a later

date, and affords considerable interest besides oftentimes obtaining more vigorous plants. They may be sown in the open ground, but it is preferable to sow in pots or boxes and keep damped and shaded in a cold frame until germinated, when the seedlings may be pricked out into a border.

Wallflowers.—The earliest-sown plants will now be ready for transplanting on to a well-prepared piece of ground that has been made fairly firm, so that the plants will make a good sturdy growth. A border facing east will suit them admirably. Plant in rows a foot apart and allow 10 inches between the plants. Choose showery weather for transplanting, if possible, but avoid their becoming crowded and drawn.

The Shrubberies.

Rhododendrons.—Now that the flowers are past, the bushes will present a much neater appearance if the old flower-trusses are picked off. If carefully done, they will readily part from the stems. Give the beds a good mulching of decayed cow-manure and leaf-mould or rough peat, as this will benefit the young growths now being formed. The same remarks apply also to Azaleas.

Ceanothuses.—These are making a good display in the shrubberies and are, practically speaking, hardy. Of *Ceanothus azureus* there are some excellent varieties, and these are well adapted for planting against balustrades and walls. Indigo, as its name implies, is a beautiful deep blue. Perle Rose is another excellent sort, as is also Gloire de Versailles, a vigorous variety.

Ononis rotundifolia.—This is a charming shrubby plant for the front of the shrubberies. It is easily raised from seed, which may be sown as soon as ripe. The Pea-shaped flowers are freely produced over a long season. It is also a suitable plant for the rockery.

Hypericum olympicum.—This is now a sheet of golden flowers, and also well adapted for the rock garden. As soon as the young growths that follow the flowering period are large enough, insert them in sandy soil and keep close in a cold frame, when they will soon root.

E. BECKETT, V.M.H.

Aldnam House Gardens, Elstree, Herts.

FOR NORTHERN GARDENS.

Hardy Shrubs.

Young Plants.—New *Deutzias*, *Philadelphuses* and any others rooted early in the year in heat and now well established in pots may be planted out in well-fertilised soil, where, before winter, they will be thoroughly established.

Ivy.—A considerable quantity of Ivy is left untrimmed till about this time, when it is closely shorn, and never fails to clothe itself with new foliage in not more than a fortnight. Where the family is in residence, this operation cannot, of course, be done at this season.

Clematis montana.—Now that the flowers are past, this early species should be hard pruned, but removing only the last year's shoots. It is best trained on arches or pergolas where the young growths can hang down, which in May and June form wreaths of lovely white blossoms.

Rosa alpina.—This early-flowering species makes a felicitous addition to the shrubbery, foliage, wood, flowers and fruit being alike handsome. It is noted for its beauty in "The Guild of Garden Lovers," but without name. It should never be pruned unless when the wood in any portion gets worn out. Given space to extend, it throws out suckers in every direction, and forms in the course of a few years a most attractive object.

Fruit-Houses.

Shading Vines.—In very hot weather do not hesitate to apply a thin shade of whitening dissolved in pure water to the glass of vineries where the Grapes are at a stage to scald. If forced upwards from a syringe, the whitening falls in spots and breaks the force of the sun's rays without unduly affecting the entrance of light.

Peaches.—Those freed of a crop may have a portion of the old wood removed, in order to give more space to that of the current year, which need not be more than required for next season's cropping. Ripening fruit may be gathered, if abundant,

before it is quite matured and stored in a perfectly cool fruit-room, where it will keep for a fortnight at least. Peaches are invariably improved in flavour when picked a day or two before being eaten.

Melons.—These will grow exceedingly fast; and after laying in a sufficient amount of growth to carry the fruits to maturity, it is very important that all the new growths which push from the axils of the main leaves be rubbed off as soon as they are large enough to handle. They are of no value to the plants, and, as a rule, are the first parts to be infested with red spider. Melons may be freely ventilated in fine weather if there is no hurry for the crop to ripen, being comparatively hardy during the summer months.

The Vegetable Garden.

Seakale.—Previous to the foliage quite covering the surface of the soil it is advantageous to apply a dressing of manure.

Peas.—As these are picked clean, the haulm should be cut over at the surface of the ground and cleared away. Besides being an eyesore, the foliage becomes a prey to mildew, which, doubtless, spreads to other crops.

Cos Lettuces.—These are better-eating than Cabbage Lettuces at this season, and they come much finer when the seedlings while still small are transplanted into very highly-manured soil. Hicks' Hardy is a variety that hearts without the necessity for tying the heads. It is a safe precaution to draw the roots through a mixture of soil and water previous to planting, and the ground should be prepared by drawing a deep drill so that they are set in soil that has not been surface-dried.

Tomatoes.—In some years these fruit fairly well when trained to warm walls, such as those of hothouses. In such instances the crop should be strictly limited to three clusters at most. It is a temptation to be always applying water, but, provided the soil is good and made firm at the time of planting, they are, as a rule, better for not being watered. It is hardly necessary to say that only the main foliage need be preserved.

Seeds to Sow.—A little Endive, white-skinned Turnips, Spinach, Lettuces and Radishes at least. All are better to have the drills saturated with water an hour or two previous to sowing, for Spinach in particular, which should be sown in extra deep drills, which need not be filled in level with the surface. Given plenty of moisture and a friable, fertile soil, the modern Spinach produces fairly large leaves even at this the worst season for it.

The Plant-Houses.

Potting.—All kinds of early winter-flowering plants should be potted into their flowering receptacles without delay.

Chrysanthemums.—Bush plants should not be stopped after this. A look-out should be kept for aphids in the points of the shoots, and tobacco powder applied should it appear. The plants will now require looking over on hot days twice daily, lest they should suffer from over-dryness at the root; all the same, do not over-water.

The Flower Garden.

Carnations.—These may now receive their final tying, and the buds be reduced in number should large blooms be essential. Border varieties in pots are now in bloom, and should be layered as soon as possible.

Lupinus polyphyllus.—There is a great variety in this handsome border plant—pink, rose, creamy white, as well as the old varieties. The primary spikes are now going over, and should be cut off before many seeds are set to enable the plant to throw up successive spikes, which plants not too old will do, provided this is done in time.

Roses.—Continue to arrange and tie the shoots of climbing varieties, which are now extending at a great rate. If standards have not yet been thinned of weakly shoots which do not show flowers, they should be removed at once. Also reduce the number of buds on very floriferous varieties, and apply another surface-dressing of quick-acting manure to enable the bushes to go on flowering, that is, to the Hybrid Teas. Take prompt measures with aphids and mildew should they appear. It is rather early in the year for orange fungus, but a sharp look-out for this also must be kept.

R. P. BROTHURSTON.

Fyninghame, Prestonkirk, N.B.

NEW AND RARE PLANTS.

FIRST-CLASS CERTIFICATES.

Lælio-Cattleya Baroness Emma.—This is a beautiful Orchid derived from the intercrossing of *L.-C. eximia* and *Cattleya hardyana*, so four species, viz., *C. gigas*, *C. aurea*, *L. purpurata* and *C. Warneri*, are concerned in its ancestry. The sepals and petals are a pleasing shade of mauve, while the large expanded lip is a rich purplish crimson, with a yellow area in the throat. Shown by Baron Bruno Schröder, The Dell, Egham.

Odontioda Cooksoniæ Fowler's variety.—A charming form of this popular hybrid, whose parents are *Cochlidia noetzliana* and *Odontoglossum ardentissimum*, but probably the latter was a very fine variety to produce such remarkable results. The sepals and petals are red, with a thin margin of a purplish hue, while the lip has a golden crest and a white front lobe. The flowers are about two and a-half inches across, and at first sight one would take it for an *Odontoglossum*. Surely the "scarlet" *Odontoglossum* has now arrived. Exhibited by Messrs. Charlesworth and Co., Hayward's Heath.

AWARDS OF MERIT.

Carnation Mrs. Husan Morris.—A self border variety of salmon rose colour, and of shapely appearance. Exhibited by S. Morris, Esq., Thetford.

Begonia James Braid.—A gloriously beautiful tuberous-rooted variety of intense crimson colour.

Begonia F. W. Walker.—A counterpart of the last, but of scarlet colouring. Both are very handsome, and were exhibited by Messrs. Blackmore and Langdon, Bath.

Begonia Golden Shower.—A drooping or trailing variety well suited to basket-work, and having the colour of *Rose W. A. Richardson*. Also from Messrs. Blackmore and Langdon.

Delphinium Harry Sweatham.—A semi-double variety, with medium-sized flowers of the deepest azure blue. It is very rich and telling. Exhibited by Messrs. Blackmore and Langdon, Bath.

Delphinium Lavanda.—A very distinct mauve-coloured variety of exceptional distinction and charm. From Mr. G. Ferguson, Weybridge.

Delphinium Drake.—This is a very handsome single-flowered variety of deep, clear blue, and having a conspicuous white eye.

Delphinium Tagalie.—Royal to azure blue, semi-double and very handsome.

Delphinium Lovely.—Another bold and handsome variety, of mauve and blue colour. The flowers are semi-double. This set of three came from Messrs. J. Kelway and Son, Langport, Somerset.

Eremurus Lemon Queen.—This is apparently one of the *E. Warei* forms, with self-coloured flowers of the palest lemon yellow. Exhibited by Messrs. James Veitch and Sons, Limited, Chelsea.

Philadelphus Bouquet Blanc.—A remarkably free-flowering variety, with medium-sized, semi-double white flowers.

Philadelphus Voie Lactee.—A magnificent single white, the flowers handsome and very pure. From Messrs. James Veitch and Sons, Limited, Chelsea.

Carnation Cyclops.—A very fine yellow-ground fancy variety freely overlaid with crimson. A well-formed flower of great size.

Carnation Charles Blick.—A pure white Malmaison variety which the raiser of nearly all

the Malmaisons of commerce considers good enough to perpetuate his own name. The fact should speak volumes in its behalf. It is a wonderfully fragrant variety. These Carnations were shown by Mr. Charles Blick, Hayes, Kent.

Lavatera (Malva) Olbia.—Said to be a native of Provence, quite hardy in the southern parts of England, and a true perennial. The flowers are some three inches across, and of a pretty rosy mauve, freely borne on erect stems. Exhibited by Mr. M. Prichard, Christchurch.

Rose Effective.—A pillar variety of great promise. It is of crimson-scarlet colour, large in size and very free. Said to be the result of a cross between *Carmine Pillar* and *General Macarthur*.

Rose Pink Pearl.—A single or semi-double variety of singular beauty and charm. Its name is descriptive. These came from Messrs. Hobbies, Limited, Dereham.

Odontonia St. Alban.—A fine acquisition to this comparatively new genus, created for hybrids between *Miltonia* and *Odontoglossum*. In this instance the parents are *M. fuscatum* and *O. Pescatorei*. The flower is rather attractive, having a white ground, spotted and blotched with purple. From Messrs. Sander and Sons, St. Albans.

Miltonia bleuana Rising Sun.—Why this beautiful plant received the name of *Rising Sun* it is difficult to understand, for it is white, excepting a yellow centre. Shown by Baron Bruno Schröder, The Dell, Egham.

Lælio-Cattleya Ganymede.—This was represented by a small plant with one flower, which had apricot yellow sepals and petals and a somewhat large crimson lip for the size of the bloom. The parentage is *L. Latona* × *C. Schröderæ*, and it was exhibited by W. Walters Butler, Esq., of Edgbaston.

The foregoing were shown before the Royal Horticultural Society on June 18, when the awards were made.

AWARDS TO DELPHINIUMS AT WISLEY.

In the *Delphinium* trials conducted at Wisley during the present year, the following were considered worthy of three marks by the visiting committee, and awards of merit in each case were confirmed by the floral committee at its sitting on the 18th inst.:

Delphinium Darius.—Semi-double, creamy white.

D. Cymbeline.—Dark blue, conspicuous white eye.

D. Jessica.—Intense violet blue, white eye.

D. Lorenzo.—Rich violet purple. These were sent by Messrs. G. Bunyard and Co., Maidstone.

D. Mrs. James Kelway.—Clear Cambridge blue, white eye.

D. Smoke of War.—Violet purple, very distinct, spikes strong and handsome.

D. Dr. Lodwidge.—Metallic blue, very fine. From Messrs. Kelway and Son, Langport.

D. Mr. J. S. Brunton.—Fine clear blue, with white eye; handsome spike. From Mr. B. Ruys, Dedemsvaart, Holland.

D. Dr. Bergman, Colonel Crabbe, J. S. Sargent, Mme. E. Geny and Royal Standard.—From Messrs. Forbes and Co., Hawick.

D. Lizzie von Veen.—From Mr. J. Box, 1. ind. field.

ANSWERS

TO CORRESPONDENTS.

RULES FOR CORRESPONDENTS.

QUESTIONS AND ANSWERS.—The Editor intends to make THE GARDEN helpful to all readers who desire assistance, no matter what the branch of gardening may be, and with that object will make a special feature of the "Answers to Correspondents" columns. All communications should be clearly and concisely written on one side of the paper only, and addressed to the EDITOR OF THE GARDEN, 20, Tavistock Street, Covent Garden, London, W.C. The name and address of the sender are required in addition to any designation he may desire to be used in the paper. When more than one query is sent, each should be on a separate piece of paper. Plants for naming should be clearly numbered and securely packed in damp grass or moss, not cotton-wool, and flowering shoots, where possible, should be sent. It is useless to send small scraps that are not characteristic of the plant. Letters on business should be sent to the PUBLISHER.

FLOWER GARDEN.

SWEET WILLIAM FAILING (Mrs. A.).—The plant appears to have fallen a prey to the fungus known as *Puccinia Dianthi*, though its condition when received was opposed to a definite conclusion in the case. Sweet Williams for garden purposes are best if regarded from the biennial standpoint, raising a batch of seedlings each year and discarding them when the flowering is over. It is also a good plan to provide them with a fresh bed or new position each year, and so arrange matters that a complete change of soil and site is ensured to each batch of seedling plants. In this way a greater vigour results, while the failures are reduced to a minimum.

WHITE LUPINE DROPPING ITS BUDS (M. G. R.).—The falling is most probably due to some inherent weakness on the part of the variety, or to some chemical deficiency of the soil. It may be a combination of both, as in some localities the white form is singularly prone to the defect mentioned. Try replanting in autumn, and employ chalk or lime well worked in the soil previously. It would also be well to raise seedlings continually, as these we find much more reliable and less prone to bud-dropping than are older plants subjected to division. The leafy growth in *Rose-buds* is merely a freak of Nature. We could form no opinion in respect to the *Gloire de Dijon Rose*; the buds, as indeed all your specimens, were completely dried up. To get any idea of such things, and to be at all helpful to our readers, the specimens should be packed in damp moss so as to reach us in a quite fresh state.

TREES AND SHRUBS.

PRUNING OF RIBES AND CYTISUS (W. I.).—The various kinds of ornamental flowering *Ribes* require very little pruning other than an occasional thinning, which may be done any time during summer. Should your bushes become too large for their position, however, you may both thin them and cut them back as soon as the flowers have faded. The taller-growing *Cytisuses* should be pruned as soon as the flowers have faded. They require rather careful handling, for if cut back into hard wood they rarely do any more good; therefore do not cut the branches back below the base of the previous year's wood. In the case of old straggling bushes it is as well to do away with the plants and begin again with young stock. The dwarf kinds of *Cytisus*, as a rule, may be shortened a little after flowering, but *Cytisus purpureus* should have all the old wood removed each year to make room for young shoots, which appear from the rootstock.

THE GREENHOUSE.

SOWING SEEDS FOR WINTER FLOWERS (Seedling).—It is too late now to sow some of the recognised autumn and winter flowering subjects in order to have them in bloom at that season. Primulas sown at once will flower in the winter, but for autumn blooming, extending in some cases at least well on to the end of the year, you may sow some of the annuals that do best in pots, such as *Alonsoa Warscewiczii compacta*, *Celosia pyramidalis*, *Clarkias*, *Godefias*, *Linum grandiflorum*, *Mignonette*, *Nemesias*, *Nicotiana hybrids*, *Phlox Drummondii*, *Rhodanthe Manglesii*, *Schizanthus* and *Stocks*. You speak of a heated greenhouse, in which structure the seeds of *Primulas*, *Celosia pyramidalis* and *Nicotiana hybrids* may be raised. These, however, will only need a little heat during their earlier stages. The others had better be brought up altogether without heat, otherwise they will grow up weakly, and will consequently fail to flower in a satisfactory manner.

THE ORIGIN OF THE MALMAISON CARNATION (Constant Reader).—There is no authentic knowledge of the origin or introduction of the Old Blush Malmaison Carnation, which was the first of its race to be grown in this country. Malmaison in France was a favourite residence of Joséphine, the first wife of the Emperor Napoleon I., and the gardens were celebrated for the great number of plants grown there. Whether this variety originated at Malmaison is not known; if so, it must be at least a century old. All that can be definitely said concerning it is that it first made its appearance in this country in the fifties

of last century. For some years it was not a popular flower, the blooms being too large and misshapen for the floral ideals that then prevailed. Now, however, with the present-day taste for large blooms, it is largely grown. With regard to the varieties we now have, two or three of the oldest originated as sports from the Old Blush. One of the first to take up the raising of the Malmaison was the late Mr. Martin Smith of Hayes, Kent.

FRUIT GARDEN.

GOOSEBERRY BUSHES DISEASED (*Lady R.*).—The bushes are diseased in consequence of a virulent attack of red spider, consequent on the heat and drought of April and May. This may very well not be the only reason, seeing that your bushes growing in the open are healthy and doing well. The best thing for you to do to bring the trees round will be to pick off the fruit, and to immediately spray the trees for the destruction of the spider with the following wash, taking care to well saturate every part of the bushes. The best way of applying the wash is through a Knapsack pump or a syringe. Tobacco powder, 3lb.; soft soap, three-quarters of a pound; water, ten gallons. Preparation: Infuse the Tobacco powder in water for six hours, then strain off, press the Tobacco and infuse again. Add the Tobacco extract to the dissolved soft soap and water. Apply immediately. Afterwards give the bushes a good soaking of water and a surface mulching of rotten manure. Take away the wire-netting from the roof of the enclosure and substitute for it fish-netting when wanted to protect buds in winter and fruit when ripe in summer, but not at other times.

KITCHEN GARDEN.

MAKING A MUSHROOM-BED (*A. E. F. H.*).—A Mushroom-bed could be made at any season of the year provided the materials were ready and of the right kind. The materials consist chiefly of horse-manure or very short manure from which all the long straw has been removed. Kept apart for a time, and occasionally turned to prevent undue heating and a too early decay, we have seen excellent crops of Mushrooms produced from this material alone without spawning when subsequently introduced into warmer quarters. For example, assuming that you desired a crop of Mushrooms in September or October, the manure should be selected three months in advance, and occasionally turned, as above mentioned, during the space of a month. At the end of that time a bed of manure, 9 inches or so in thickness, should be formed under a greenhouse stage, or in a cellar or outhouse not used for human habitation. The manure should be well beaten down, and a few days later, when the heat has declined, pieces of spawn some 3 inches square should be inserted at about a foot apart over the surface of the bed, subsequently surfacing the bed with soil and making the whole quite firm. For an outdoor bed the ridge principle would be best, the making and spawning being practically the same. In this case, however, a covering either of mats or litter, or both, is essential to preserve the heat of the bed and retain those uniformly moist and warm conditions which are so necessary to success. Winter beds in the open are not suggested, though the specialist out of his knowledge can ensure success where an amateur would fail.

MISCELLANEOUS.

DESTROYING WIREWORMS (*Brendon*).—It is of no use to recommend to you the use of gas-lime to destroy wireworms, as, while it is the most destructive agent, it can only be used and dug in vacant soil, while the ground carrying crops or plants cannot be so treated. You might trap the pests. For this purpose obtain large Mangel Wurzel. Cut these up into square pieces each of about eight ounces in weight, fix into each one a stick like a skewer, 12 inches long, and so tied to the Mangel pulp that the two cannot part. Bury these portions of Mangel 4 inches to 6 inches deep in the soil wherever wireworms are in evidence, the stick standing a few inches out of the ground. Examine them every three days, lifting them carefully with a fork, removing the insects found on them and destroying them. Replace these traps in the soil, as they may be used for several weeks. You would do well to persist in the use of soil fumigants.

PRIMULAS AND OTHER QUESTIONS (*A. E. F. H.*).—The seeds of the Primulas you would probably get from Messrs. Barr and Sons, King Street, Covent Garden, or from Messrs. Thomson and Morgan, Ipswich. The Iris you submit for naming is *I. graminea*. *Myosotis rupicola* may be increased by seeds or by division of the old plants after flowering. The *Lithospermum* is best raised from fresh young cuttings inserted in August and September in a cold frame or hand-light. The Mossy Saxifrage may be pulled to pieces quite freely at any time after the flowering is past, and any portions with roots attached should be replanted. Unrooted portions might be treated as cuttings, planting them in sandy soil in a shaded frame or hand-light. In the case of divisions or cuttings it is necessary that the growth be buried up to the green of the leaves, as from this point new root-fibres issue very quickly. By inserting the cuttings sufficiently deep or by planting the divisions as suggested, compact examples result in a very short time.

NAMES OF PLANTS.—*B. W.*—1, *Cistus laurifolia*; 2, *Choisya ternata*; 3, *Quercus rubra*; 4, *Fraxinus excelsior pendula*; 5, *Eunonymus japonicus*.—*Mrs. W. S. S., Beckenham.*—Rose Francois Juranville. —*Burns.*—1, Too much withered to identify; 2, *Thymus vulgaris variegata*; 3, *Origanum vulgare*; 4, *Thymus vulgaris*;

5, *Hyssopus officinalis*; 6, *Saxifraga lindleyana*; 7, *Borago officinalis*; 8, *Dianthus Rosina*; 9, *Campanula persicifolia alba*; 10, *Dianthus Mrs. Sinkins*.—*E. B. J., Dorsetshire.*—11, *Leonie Jamesch*; 14, *White Baroness*; 16, *Billiard et Barre*; the others had fallen. Please send flowers in future in a less advanced stage and pack them in damp grass.—*R. T.*—*Rhododendron undiflorum* variety.—*H. O.*—Yes; *Iris sibirica*, it varies in colour.—*G. D. W.*—*Rubus idaeus*.—*H. H. R.*—*Muscari comosum plumosum*.—*Febbery.*—1, *Ilex diplyrena*; 2, *Scilla peruviana*.—*Enthusiastic.*—1, *Acalypha macaefeaana*; 2, *Strobilanthes dyerianus*; 3, *Anthurium* species; 4, *Dieffenbachia regina*; 5, *Acalypha hispida*.—*Mrs. Leo Walsh.*—1, *Geranium sanguineum lancastriense*; 2, *Geranium sanguineum*; 3, *Viola cornuta*; 4, *Astrantia major*; 5, *Sedum hybridum*; 6, *Rose White Baroness*.—*C. W. Bucks.*—Probably *Cornus amomum*.—*J. E.*—*Pink The King*.—*T. P. G.*—*Rose Tom Wood*; 2, *Anthemis* species.—*Mrs. L. Frome.*—*Iris sibirica alba*.—*H. J. W.*—*Rose Desire Bergera*.—*An Amateur.*—*Garden Pink Anne Boleyn*.—*J. P. Rowston.*—1, *Allium Moly*; 2, *Scilla peruviana*.—*J. W., Coventry.*—*Colutea media*.—*A. G. S. F.*—1, *Careuna* species; 2, *Hoya carnosca*; 3, *Choisya ternata*; 4, *Cupressus macrocarpa*; 5, *Asplenium Nidus*; 6, 7 and 8, too scrappy to identify; 9, *Allium scorodoriolium*.—*A. E. B.*—1, *Rhus cotinoides*; 2, *Ephedra distachya*.—*Mrs. C. Q., Suffolk (?)*.—No number. *Philadelphus coronarius*; 2, *Crambe pinnatifida*; 4, *Solanum jasminoides*; 6, probably a *Gleditschia* species (specimen too poor).

SOCIETIES.

YORKSHIRE GALA.

JUNE 19, 20 AND 21.

THIS important event in the annals of horticulture once more proved a great success. The rock and water gardens were, as usual, one of the most charming features, while the displays of Roses, hardy flowers, Orchids and stove plants contributed largely to the success of this great exhibition.

STOVE PLANTS AND ORCHIDS.

The competition was good in the important group class, and once more Mr. J. Donoghue, gardener to J. Pickersill, Esq., Wetwood, Leeds, gained the premier award. It was a magnificent group, with Rambling Roses and Palms in the background, and handsome Crotons and Odontoglossums over the centre and front.

In the premier class for Orchids on a table space of 12 feet by 5 feet, plants and cut flowers were both admitted. There were three competitors. Messrs. J. Cypher and Sons, Cheltenham, secured the first prize with a very effective arrangement of *Cattleya Mossie*, *Laelo-Cattleya Fascinator*, *Odontoglossums*, *Brassia verrucosa*, *Oncidium*, *Cymbidiums* and *Miltonias*. Second prize was won by Messrs. Mansell and Hatcher with a very beautiful exhibit of *Renanthera inaequalis*, white *Odontoglossums*, *Miltonias*, *Oncidiums* and *Cattleyas*.

As in former years, the classes for specimen stove plants aroused the keenest interest. The best collection of stove and greenhouse plants in bloom came from Messrs. James Cypher and Sons, Cheltenham, who in a space 20 feet by 10 feet arranged many famous examples of *Statie profusa*, *Erica verticosa*, *E. Cavendishii*, *Clerodendron Thomsonae*, *C. Cypheri* and *Anthuriums*. Mr. W. Vause, Leamington, came second, and he showed fine examples of *Pimelea Hendersonii* and *Erica Cavendishii*.

ROCK GARDENS AND HARDY PLANTS.

As mentioned earlier in the report, rock gardens were once more a feature of the gala. Messrs. J. Backhouse and Son, Limited, York, are to be complimented on their large rock garden and water pool; it was excellent in every respect. The old weather-worn stones gave an air of reality to the design. It was planted with hardy Orchids and Primulas and a good assortment of the best subjects in season, with appropriate shrubs at points of vantage. Second, Messrs. W. Artindale and Co., Sheffield, who banked large masses of rock at the back, with a pathway at the foot, leading by a narrow stream. The front was gay with alpine flowers, while bold trusses of *Rhododendrons* dominated the higher parts of the background. Third, Mr. S. Pickering, 31, Rosslyn Street, Clifton, York, who exhibited a very meritorious design.

Messrs. J. Backhouse and Son secured first prize for a collection of hardy herbaceous perennials. We can, however, hardly say that it came within the category of a herbaceous border. The plants included *Paeonies*, *Liliums*, *Lupines*, *Irises*, *Achusa*, *Pyrethrums*, *Campanulas*, *Gladioli*, *Lychnis*, *Aquilegias*, &c., all tastefully arranged. Second, Messrs. W. Artindale and Son, who showed splendid spikes of *Ercmuri*, *Lupines*, *Verbasum pannosum*, *Delphiniums* and *Liliums* grouped among *Irises*, *Paeonies*, *Pyrethrums*, *Campanulas* and the like, all of excellent quality. Third, Messrs. G. Gibson and Co. Bedak.

Twenty alpine and herbaceous plants in pots.—This class was staged out of doors, and the exhibits numbered three. Much the best display was made by Mr. Walter Pybus, Monkton Moor, Leeds. His plants included *Nepeta violacea*, *Mimulus Filiagii*, *Campanula turbinata*, *Saxifraga pyramidalis* and *Achillea Ptarmica* The Pearl. Second, Mr. S. Pickering; *Cerastium tomentosum*, *Phlox canadensis*, *Geranium pratense* and *Funkias* were noteworthy plants in this group. Third, Mr. G. W. Planky.

ROSES.

We never remember having seen Roses shown in better form at York than on this occasion. In the class for

seventy-two blooms, not less than three dozen varieties, Messrs. D. Prior and Sons, Colchester, were the winners. A few of the best blooms were Hugh Dickson, Florence Pemberton, Mrs. W. J. Grant, A. K. Williams, Bessie Brown and Mme. Jules Graveaux. Messrs. Frank Cant and Co., Colechester, came second, with Messrs. Jarman and Co., Chard, third.

For forty-eight blooms, likewise for thirty-six blooms, Messrs. D. Prior and Sons were again successful.

Five competitors staged two dozen blooms, and here Messrs. Frank Cant and Co. came to the front with fine examples of *Gloire de Chedane Guinisseau* and *Dr. O'Donnell Brown*. Messrs. D. Prior and Sons were second.

The premier award for eighteen Roses, distinct, fell to Mr. George Prince, whose examples of *Ethel Malcolm*, Mrs. Hubert Taylor, Bessie Brown, Mme. Jules Graveaux, W. Shean and *Lady Ursula* were notably good. Messrs. D. Prior and Sons were second.

FRUIT CLASSES.

The most important class in the fruit section was for a decorated table of ripe fruit arranged on a space 10 feet by 4 feet 6 inches. Eight points were allowed each for black and white Grapes, Peaches, Nectarines and Pineapples, all other fruits to be given a maximum of six points. The flowers and their arrangement carried twenty-four points as a maximum. There were three competitors, and each showed well, the first prize being won by the Duke of Westminster, Eaton Hall (gardener, Mr. N. F. Barues). The fruits in this exhibit possessed high quality, and the decorations were light and graceful. The fruits included *Grapes Madresfield Court* and *Muscot of Alexandria*; *Nectarines Lord Napier* and *Pineapple*; *Peaches Royal George* and *Peregrine*; *Apples Etonian* and *James Grieve*; *Plums Jefferson's* and *Kirke's*; *Pears Triomphe de Vienne* and *Dr. Jules Guyot*; and *Melons Hero* of Lockinge and *Eaton Seedling*. The points awarded were: *Grapes*, 23; *Nectarines*, 13; *Peaches*, 13; *Apples*, 10; *Plums*, 9; *Pears*, 10; *Melons*, 9; which, with 20 points for decorations, made a total of 109 points. The second prize was awarded to the Duke of St. Albans, Bestwood Park, Arnold, Nottinghamshire (gardener, Mr. J. Edmonds). This exhibitor obtained 95 points, his best fruits being *Grapes Black Hamburg*, *Strawberry Royal Sovereign* and *Nectarine Lord Napier*.

The Duke of Newcastle, Clumber, Worksop (gardener, Mr. S. Barker), was first for a collection of ten kinds of fruits, with good bunches of *Foster's Seedling* and *Black Hamburg Grapes*, *Royal Sovereign Strawberries* and *Early Transparent Plums*.

We were sorry to note a serious falling off in the vegetable classes.

NON-COMPETITIVE.

Messrs. Sutton and Sons, Reading, had an exhibit of flowers and vegetables. *Melons*, *Tomatoes*, *Peas*, *Beans*, *Marrows*, *Carrots*, *Potatoes*, also other kitchen garden produce, were represented in high-quality vegetables. Large gold medal.

Robert Sydenham, Limited, Birmingham, filled rustic metal flower-holders with varieties of *Sweet Peas*, relieved with *Gypsophila*, an admirable method of displaying these pretty flowers.

Messrs. W. Cutbush and Son, Highgate, showed *Car-nations* and greenhouse plants. Special gold medal.

Messrs. Edward Webb and Sons, Wordsley, Stourbridge, staged an exhibit with flowers and vegetables. Against a background of *Hydrangeas*, *Lilies* and *Sweet Peas* were arranged *Melons*, *Tomatoes*, *Carrots*, *Beet*, *Peas*, *Onions* and other produce from this firm's seeds. A central batch of *Gloxinias* and tall *epergnes* of *Sweet Peas* at either end provided a pleasing setting to the collection. Large gold medal.

Messrs. Dobbie and Co., Edinburgh, had a grand collection of *Sweet Peas*. The varieties included *Dobbie's Scarlet*, *Elfrida Pearson* (soft pink), *True Lavender*, *Mrs. Cuthbertson* (rose and white), *Edrom Beauty* (rose, with orange standard), *Thomas Stevenson* (a magnificent vase of this beautiful orange red variety), *Lavender G. Herbert*, *Melba*, and *May Campbell* (rose marbling on cream). Large gold medal.

Mr. C. W. Bredmore, Winchester, showed 100 vases of *Sweet Peas*, representing about forty varieties. Silver-gilt medal.

Mr. W. J. Unwin, Histon, showed a choice exhibit of *Sweet Peas*. Silver medal.

Messrs. E. W. King and Co., Coggeshall, Essex, showed *Sweet Peas*, having specially good vases of each fine sort as *Mrs. Hardestack Sykes*, *Stirling Stent*, *Thomas Stevenson*, *Constance Oliver*, *Nora Unwin*, *Mrs. Cuthbertson*, *Mrs. W. J. Unwin* and *Helen Lewis*. Large gold medal.

Miss Hemus, Upton-on-Severn, exhibited *Sweet Peas* and *Iceland Popples*, the *Sweet Peas* including the varieties *Evelyn Hemus*, *Primrose Paradise*, *Helio*, *Holdfast Belle* and *Midnight*. Silver medal.

Messrs. Charlesworth and Co., Hayward's Heath, arranged a collection of choice *Orchids* in the special tent for these flowers. Notable plants were *Laelo-Cattleya canhamiana alba*, *Cattleya Mossie Wageneri*, *Odontoglossum Aireworth* and *Cattleya Mossie reinckiana*. Large silver-gilt medal.

Messrs. Sander and Sons, St. Albans, contributed a fine group of *Orchids*. Gold medal.

Messrs. Mansell and Hatcher, Rawdon, Leeds, showed choice *Orchids*, including well-flowered plants of *Cypripedium Smithii* and *Laelo-Cattleya Martinetii*. Silver-gilt medal.

Mr. J. E. Sadler, Newbury, Berkshire, showed *Odontoglossums* and *Odontodias* in a setting of *Ferns* and hardy flowers. Silver medal.

Mr. Clarence Elliott, Stevenage, had a miniature rock garden planted with *Thymus Serpyllum*, *Dianthus deltoidea albus*, *Nepeta Mussinii*, *Viola gracilis*, *Campanula Miss Willmott*, and *Oxalis enneaphylla*. Silver-gilt medal.

EDITORIAL NOTICES.

Every department of horticulture is represented in **THE GARDEN**, and the Editor invites readers to send in questions relating to matters upon which they wish expert advice.

The Editor welcomes photographs, articles and notes, but he will not be responsible for their safe return. All reasonable care, however, will be taken, and where stamps are enclosed, he will endeavour to return non-accepted contributions.

As regards photographs, if payment be desired, the Editor asks that the price required for reproduction be plainly stated. It must be distinctly understood that only the actual photographer or owner of the copyright will be treated with.

The Editor will not be responsible for the return of artistic or literary contributions which he may not be able to use, and the receipt of a proof must not be taken as evidence that an article is accepted. Publication in **THE GARDEN** will alone be recognised as acceptance.

Offices : 20, Tavistock Street, Covent Garden, W.C.

NOTES OF THE WEEK.

Apples Damaged by Hail.—We have received from a correspondent at Grimsby some Apples that were damaged by a hailstorm there on the 19th ult. The fruits were very badly bruised, and in many instances pieces were cut clean out. Our correspondent states that fully 90 per cent. of the fruits on the trees were damaged in this way.

The Spanish Broom.—This handsome Broom, botanically known as *Spartium junceum*, does not appear to be fully appreciated, for one sees it planted less frequently than the various Brooms that flower earlier in the year. It is well adapted for planting on poor and stony soils. The large golden flowers appear early in July, and are generally at their best towards the end of that month and early August.

Geranium Fremontii.—This is a neat, hardy Geranium, or Crane's-bill, from Colorado, which is doing well, and is quite hardy, after having been well tested for several years. It does not grow very rapidly, and makes a neat plant about a foot high, with purplish flowers. In its general appearance and colour it is unlike most of the other hardy Crane's-bills. On a rather dry border it thrives excellently, and is generally appreciated.

Abelia floribunda.—This charming shrub is not too frequently seen in the open in Scotland, or, for that matter, in all but a few favoured parts of England, so that it was with much pleasure that we came across it doing quite well in the garden of Mr. Carrick-Buchanan, Corsewall, Stranraer. Corsewall is situated in one of the mildest districts in Scotland. Here *Abelia floribunda* not only stands the winters well, but blooms freely, giving good clusters of its purple flowers.

Disbudding Roses.—There is an inclination on the part of many Roses this year to produce an over-abundance of bloom. By the removal of side buds the central bud has a much better chance of reaching perfection. Disbudding is regularly practised by Rose exhibitors: but in a year like this, when standard and bush Roses endeavour to produce six blooms when there is only room for one, the thinning-out of flower-buds is much to be commended, even among Roses grown for garden effect.

Cordylone (Dracæna) stricta.—A correspondent sends us from North Cornwall flowers and leaves of this useful Australian plant, with the interesting information that a plant has been flowering outside 7 feet in height. It is only in Cornwall and similarly favoured localities that it is possible to cultivate *Cordylone stricta* out of doors. In most gardens where it is grown the plant finds a place in a cool

greenhouse, while plants will live for many years in the window of a dwelling-house provided it gets a fair amount of light. The small, light blue flowers are freely produced in large panicles. The green leaves are long and narrow.

Campanula persicifolia Moerheimi.—Of the numerous varieties of *Campanula persicifolia*, this is undoubtedly one of the best of the set, and is equally valuable either as a border plant or for producing a quantity of long-stemmed flowers for cutting. The flowers are of the purest white, and are arranged in the usual campanulate form. It gives an impressive and sumptuous effect when liberally planted, and with its lasting qualities signal it out as a plant of distinct merit. It flowers during June and July, and is readily increased by division.

A Pretty Flowering Plant for the Greenhouse. There is just now in the greenhouse at Kew a double form of the Feverfew bearing the name of *Chrysanthemum Parthenium flora-plena*, which is a decidedly useful subject for decorative purposes at this season. The plants, which are freely branched, are from 18 inches to 2 feet in height, and each bears a profusion of pure white double, rosette-like blossoms a little over half an inch in diameter. A plant of easy culture, it is well worthy of a note from its distinct character and profusion of blossoms. From a decorative standpoint its effectiveness is heightened when associated with bright-coloured subjects.

A Showy Greenhouse Plant.—The greenhouse at Kew is famous for its groups of showy flowering and foliage plants, for, visit it whenever one will, there is always much to admire and little to criticise adversely. On the occasion of a recent visit we were charmed with two large groups of varieties of *Jacobinia magnifica*, which were composed of exceedingly well-grown and well-flowered plants. The varieties in question were *carnea* and *pohlana*, and we commend them to the attention of those people who have to keep a conservatory gay. Too often these plants are allowed to become leggy, but owing to careful cultivation the Kew plants were but from 12 inches to 18 inches high, with many strong branches, each one terminated with a fine inflorescence of showy red flowers. By growing in comparatively small pots it is necessary to feed such plants well if they are to be flowered in the best condition; therefore care must be taken to avoid anything in the nature of a check from the time the cuttings are rooted until the plants flower. By rooting cuttings at intervals and paying attention to stopping, batches of plants may be obtained to last over a considerable period. The effect of one of the groups at Kew is assisted by the help of a few plants of *Marguerite* Mrs. F. K. Sander.

CORRESPONDENCE.

(The Editor is not responsible for the opinions expressed by correspondents.)

Rubus deliciosus.—Last year we had a little controversy, as I maintained that *Rubus deliciosus* seldom produced seeds, and I have just seen, in the issue for June 2, 1900, page 396, my remarks mentioning my then experience. I have brought here two seedlings raised that year. In 1899 there were letters from those who had for the first time obtained seeds, I am sure; but, unfortunately, that volume is one of only a few volumes of THE GARDEN which I have not got, so I could not refer to it. The seeds germinated very well in the open ground, whereas some sown in a pot were much later in germinating. The scarcity with which seed is produced is most remarkable.—J. R. DROOP, *Misbrooks, Capel, Surrey.*

Rose Conrad F. Meyer.—In THE GARDEN of June 8 there was an article in praise of *Rose Blanc Double de Couvert*, with which I fully agree. I should like to say a word myself for that beautiful *Rugosa Conrad F. Meyer*. I have large bushes of it in front of a shrubbery, where they show up well against the green background. About the middle of May it began to bloom, and it is still in flower (June 24). I am able to cut great bunches of the beautiful pink blooms on long, strong stems, which are so easy to arrange in water. The blooms are nearly as full and well shaped as *La France*, and almost as sweet-scented, which says a great deal. It is already throwing up great, strong shoots, 4 feet to 6 feet long, for next year. It ought to be a good hedge *Rose*, though I have not tried it so myself. In the autumn it blooms again almost as freely as in early summer. Its only drawback is its thorny stems.—AN ESSEX READER.

A Beautiful Bellflower (*Symphandra Wanneri*).—One may go a long way without coming across *Symphandra Wanneri*, sometimes called *Campanula Wanneri*, and I was pleased to see it at the Chelsea Exhibition, where it was shown by Messrs. Artindale. This Transylvanian plant has been for some time in cultivation, but is by no means plentiful. Even seeds are seldom offered, and are absent from many good catalogues of dealers in such out-of-the-way things. It is usually recognised as a biennial, and appears as such in most works of reference. I am not sure, however, that this is an invariable habit, and from what I have learned I imagine that it is a perennial in a few British gardens. Perhaps some of your readers who have had it may clear up the point. With me it proved a biennial when I grew it some years ago, although its sister flower, *S. pendula*, is a true perennial. *S. Wanneri* and *S. Hofmannii* were, however, only biennials. *S. Wanneri* was very well shown on the occasion mentioned, and it is a really pretty plant among the many beautiful ones of the race of Bellflowers, of which the *Symphandras* form a section. About six inches high and of good habit of growth, it is a pretty rock plant with its pleasing blue flowers.

Anemone palmata.—Some discussion on the difficulty of establishing the handsome *Anemone palmata* and its variety *alba* would probably be useful to many who experience some trouble with it. It is within the knowledge of the writer that there are many who have tried this *Anemone* frequently, and have procured roots at the usual time when their bulbs are received, but who, after repeated trials, have to admit that they cannot

establish it. There are a few gardens in which *A. palmata* is almost a weed; and the writer has in view one in which it seems to strive to take possession, not unsuccessfully, of two borders in a Northern garden. But plants taken from there are difficult to induce to grow, even if removed at times when they are growing freely enough, both before and after flowering. This is a very beautiful *Windflower*, especially in its white form, *alba*, which is the cause of this note being written, from the fact of the writer coming across a nice plant at the foot of a wall in a Scottish garden and in flower. Growing to about a foot high and showing admirably among other plants, *A. palmata alba* was very pretty there. The question is, why does it give so much trouble? It has ways of its own and thrives admirably in some places, but is a failure in others.—S. A.

A Beautiful Australian Shrub.—*Ozothamnus rosmarinifolius*, a charming Australian shrub, now called *Helichrysum rosmarinifolium*, but best known in gardens as *Ozothamnus rosmarinifolius*, is in full flower here, having survived for some five years or so on a south-west wall, partly sheltered from the colder winds by a bay window. It is flowering very well this season, and has quite recovered the cutting-back it received from the winter of 1910-11, when it was injured but not cut to the ground. Unfortunately, it is only suited for the warmer parts of the country, or for selected situations on walls. The writer has nowhere seen it so fine as in Ireland; but it is rather curious that in gardens which are in warmer parts than this, *O. rosmarinifolius* cannot be retained for long. Probably the soil and exact situation afforded it have a good deal to do with the matter. Here it gets full sun, a dry, rather stony soil and the fullest drainage, and a high, open position. It has never had any protection in winter. It is very beautiful with its neat foliage almost covered with thousands of its little white flowers.—S. ARNOTT, *Sunnymead, Dumfries.* [We have seen this shrub growing and flowering freely in clay soil in Essex in the open garden. It is evidently hardier than is generally supposed, unless there are two varieties.—ED.]

Garden Pests.—I have lately been trying some simple experiments for the discomfiture or destruction of such common enemies as sparrows and slugs, and I send you a brief account for publication in the hope that it may be of some service to those who, like myself, may be described as "amateur gardeners." During April I sowed afresh some thin patches on my tennis lawn with the best grass seed, covering them with netting. The usual result followed: the sparrows took the seed through the meshes, so that before the month was out I had scarcely a sprout of grass as a reward for my trouble. During the first week in May I sowed the patches afresh, covering them this time alternately with soot and Sanitas Powder, but without netting. The month being dry as a whole, both succeeded admirably; the sparrows were balked and the seed germinated. I tried the same experiment on putting out my seedlings in the flower-borders, in the hope of a similar result with slugs. Here the advantage was decidedly with the powder, as the showers soon washed away the soot, while the powder seemed to withstand them more effectively. Whatever the cause was—whether it was the more powerful smell of the powder that remained or not I cannot say—the plants around which I placed it were not eaten, and are now looking strong and healthy. I found it easier to sprinkle the powder on the spot intended for the plant, next to make the hole and insert the plant.

This powder is inexpensive if bought by the keg, and goes a long way.—A CONSTANT READER.

Exhibiting Daffodils.—I see Mr. W. A. Watts, June 22, page 314, is again on the warpath in his campaign against what he considers unfair ways of exhibiting Daffodils, and really I must say that this time, at any rate, he makes out rather a poor case. He instances an otherwise normal flower which had a refractory petal supported artificially. Well, if the flower had been normal it would not have had the refractory petal, and therefore I contend that the paper support was an aid to showing the flower in its true and correct form. I see no cause for "irritation" (or something stronger) in such a simple device. I suppose Mr. Watts would have stuck up the flower just as it was. I should not go to look at it! I am sorry to differ with such a keen florist and charming personality as Mr. Watts.—F. HERBERT CHAPMAN.

—Two letters in THE GARDEN of June 29, but no names. Why no names? "A Small Exhibitor" tells us that faking is improving to bad flowers; I do not grudge him this satisfaction! He speaks of "artistic" faking, protests that it is "above board," and commends it as a means by which he and other small exhibitors with bad flowers can gain some advantage over the big men. With good flowers is this any recommendation? I have seen far more faking among the big men than the little ones! Surely, too, when he talks of *débutantes* appearing at a *Levé* he is giving his fancy too free a rein. Then there is "A. C. C. R.'s" letter. Again, why only initials? He would put words into my mouth that I have never spoken, and pays but a poor compliment to judges in general. Certainly I would advise "A. C. C. R." to follow a lead if it is a good one, but do not follow "A Small Exhibitor" with his doubtful methods. I assure him that the public want to see good flowers, shown as grown and tastefully arranged. They do not want to see "moderate or worse" blooms faked into shape in order to enable "A Small Exhibitor," or even a large one, to gain prizes against those who show their flowers honestly.—W. A. WATTS.

The Cherokee Rose.—I have a word to add to the paragraph on this subject in the issue of THE GARDEN of last week, page 326. This Eastern Asiatic Chinese and Japanese Rose was long ago introduced into the South-Eastern States of North America, and soon became so thoroughly naturalised in a wild condition that botanists of upwards of a century ago took it to be a native species. The history of its introduction into North America is not on record, so far as my investigations go; but André Michaux, in his "*Flora Boreali-Americana*," Vol. I., page 295 (1803), described it, under the name of *R. lavigata*, as a native of America. At an earlier period (1759) it reached this country, and appeared in the second edition of Aiton's "*Hortus Kewensis*" (1810—1813) as *Rosa sinica*, a name by which it was then generally known here. This name was given to a Chinese Rose by Linnæus; but Sereno Watson, a comparatively recent monographer of the North American Roses, arrived at the conclusion that Linnæus' *R. sinica* is the same as his *R. indica*. Hence there is no choice, and we must use the name given by Michaux. *Rosa lavigata* demands a more sunny climate than the British, and reaches perfection in the Mediterranean region, in the Canary Islands and in the South-Eastern States of North America. I have seen no wild specimens of this Rose from the Himalayas.—W. BORRING HEMSLEY.

The Seeding of Daffodils.—I notice the Rev. J. Jacob wrote recently on the seeding of Daffodils this season. The outstanding and remarkable feature noticeable here is the scanty quantity of seed produced in each pod. Pods have swollen up as usual, but in a great many cases what looks like a well-filled pod turns out to contain only about half-a-dozen seeds. I wonder if this has been the experience of others, and what the explanation may be.—F. HERBERT CHAPMAN, *Ryc.*

Primula Unique.—In your issue of June 22, on page 313, we note a short article respecting *Primula Unique*. It does not appear to be known by you that this *Primula* was raised simultaneously by ourselves and Messrs. Veitch from the same cross. The Lissadell hybrid was raised about the same time, also from the same parentage, but differs slightly in colour. The plant raised by Messrs. Veitch and the hybrid raised by ourselves, however, are, we believe, quite identical.—BEES, LIMITED.

Zonal Pelargoniums.—The correspondence in *THE GARDEN*, pages 290, June 8, and 302, June 15, respectively, is very interesting to lovers of these flowers. I am quite sure that they are gaining favour rapidly year by year. We have some very beautiful varieties to grow now, and new ones are being introduced every year. I think the true colour of the flowers of the variety *Hall Caine* is cherry red with a faint suffusion of salmon in it. Personally, I do not care for second trusses of flowers borne on the first. The variety *Phyllis* is one of the very best, both as regards flowers and habit of growth. Another, *J. M. Barrie* (*cerise*), is in the front rank; *Mrs. G. Cadbury* is a lovely salmon, and *Barbara Hope* a grand salmon pink. There is a decided orange tint in the flowers of the newer doubles; *Golden Glory*, *Fascinator* and *M. A. Arckenar* should find a place in every greenhouse. *Dagata*, a double rosy mauve, has a fine habit and constitution and bears immense trusses. Some readers may not know that *Paul Crampel* is a splendid autumn and winter bloomer.—G. G.

Euphorbia Wulfenii.—I send you a photograph of *Euphorbia Wulfenii*, which is flowering with me for the first time. It is 4 feet high and has sixty-two flower-heads, most of which are about a foot long and nine inches wide. It has been growing on a mound of light, sandy loam in a sheltered but sunny position. It was given me by Miss Jekyll about four years ago, and was then probably two or three years old. This year it has been a very striking plant, the great size of the yellow-green flower-panicles, densely packed with the cup-shaped bracts and flower-heads, forming a mass of compact inflorescence rarely seen in a plant of this size. During its growth I watered it pretty regularly, but through the drought of last summer it had no attention, which probably gave it

the conditions of heat and aridity which it likes.—ALFRED R. WALLACE, *Old Orchard, Broadstone, Dorset.* [An illustration of *Euphorbia Wulfenii* in Miss Jekyll's garden appeared in *THE GARDEN*, January 22, 1910. It is an interesting Spurge that has been the subject of much correspondence in our pages. Unfortunately, the photograph of the remarkable plant grown by our correspondent does not lend itself to reproduction.—ED.]

FORTHCOMING EVENTS.

July 8.—United Horticultural Benefit and Provident Society's Committee Meeting.

July 9.—National Rose Society's Show at Regent's Park. National Sweet Pea Society's

THE ROCK AND WATER GARDEN.

DIANTHUS NEGLECTUS.

OF the many alpine members of the *Dianthus* family, *D. neglectus* is one of the very best, growing only 3 inches or 4 inches high (even when in flower), and with narrow, tufted, grass-like foliage. It is a particularly dainty little plant for a choice place in the rock garden, in gritty soil composed of loam, leaf-mould, sand and broken brick in about equal proportions. In June the hummocks of minute leaves are studded with lovely rich carmine flowers of the most intense shade, about one inch across, while the under side of each petal is of a particularly pleasing buff colour. This is apparent as the flowers close at evening. Like most of the *Dianthus* family, this species crosses very readily with any others that may be near it, and unless protected it is generally impossible to secure pure seed.

Very often when raising *D. neglectus* from bought seed the produce is far from satisfactory, doubtless due to the foregoing fact. Cuttings can, however, be taken at this season, and pieces an inch or so long strike fairly readily in a close frame. I find full sun is the best position in my garden for this beautiful Pink, while with me it also thrives in the moraine. Unlike many of the higher alpine Pinks, it seems quite devoid of that bad habit of "going off" suddenly—for no apparent reason—it being really a very good perennial. Everyone who has a choice place in the rock garden—perhaps associated with the dwarf and slower-growing Saxifrages—should try this lovely Glacier Pink. R. A. M.

A FREE-GROWING ANEMONE.

(*A. BLANDA SCYTHINICA*.)

FOR those who cannot obtain, or retain when obtained, *Ranunculus anemonoides*, there is an excellent substitute in this *Anemone*, for it is cheap to buy, easily grown, and in its satiny white purity of full expansion very much like the more difficult plant. But

when closed it shows its true nature, for the backs of the sepals are deep blue, as in the typical *A. blanda*, instead of flushed with rose as in the *Ranunculus*. Perhaps it is most beautiful when half expanded in the early morning, so that while the clear white interior is visible, the sapphire blue reverse is in evidence also. A free seeder, it soon spreads about in the rock garden or sunny border, and seems to come much more truly from seed than one would expect of such a bicolor variety. In fact, I have a belief—not founded on experience, however, for I have never grown it in an isolated position—that if it were not near the ordinary blue form, the seedlings would all be of

THE DWARF GLACIER PINK (*DIANTHUS NEGLECTUS*).

Show at Royal Horticultural Society's Hall, Westminster (two days). Wolverhampton Floral Fête (three days). Royal Scottish Arboreal Society's Exhibition at Cupar (four days).

July 10.—Torquay Sweet Pea Show. Hereford Rose Show. Elstree Flower Show. Bath Rose Show (two days). Beckenham Flower Show. East Anglian Horticultural Society's Meeting. Reigate Flower Show.

July 13.—Woking Sweet Pea Show. Purley Rose Show.

the variety *scythica*. It is best to purchase and plant these tuberous *Anemones* as early as possible in late summer or early autumn, and, that done, to leave them alone and see that the young seedlings are not hoed off for the sake of tidiness, that bane of happy, well-meaning young seedlings in so many gardens. E. A. BOWLES.

TREES AND SHRUBS.

FABIANA IMBRICATA.

AS 1866 and 1912 will always be remembered by horticulturists and botanists, so will 1851 and 1886 be always remembered, that of the former year as the first International Exhibition, and the latter date as that of the Colonial and Indian Exhibition at South Kensington. At both of these exhibitions, as well as at the intermediate ones, vegetable

in almost any soil, and is said to be readily increased by cuttings. I am induced to draw attention to this plant because of its success in my garden, as well as for its economic uses. About three years ago I planted one which at the time was about a foot or fourteen inches high; it has now grown to about six feet, with long, pendent, Heath-like branches crowded with small leaves and pure white flowers, which began to open at the end of April, lasting till the first week in June. The position is in front of a low wall and faces west; consequently it is protected from the east, as well as partially from the north and south. It is perfectly hardy here, and never has any artificial protection. JOHN R. JACKSON.

Claremont, Lymington, Devon.

THE QUINCES.

ALTHOUGH Quince fruits are used to some extent for culinary purposes and the seeds are made use of by pharmacists on account of their mucilaginous

Cydonia japonica is also widely planted throughout the country, and is very popular for wall culture. The other three kinds are less generally grown.

Description of Species.

Cydonia cathayensis, a Chinese species, is rarely met with in this country. One of the best examples belongs to Canon Ellacombe, and is to be seen in his famous garden at Bitton Vicarage. A strong-growing bush, it may be recognised by its spiny branches, dark green leaves 4 inches or 5 inches long, and pink and white flowers, which are $1\frac{1}{2}$ inches across. The fruits are bright green, 3 inches to 4 inches long and 2 inches in diameter.

C. japonica, the well-known Japanese Quince, is popular in the North of England for planting against cottage walls, where it is often known by no other name than "Japonica." In the South it forms a large bush in the open ground and flowers profusely. A very large example existed a few years ago in the at one time famous Wimbledon House Gardens. This specimen must have been upwards of twelve feet high and twenty feet through, and it always blossomed well. The most familiar colour of the flowers is bright red, but there are forms with dark red, white, striped, pink and yellowish blossoms. Candicans, white; Inteo-viridis, greenish yellow; cardinalis, deep red; princeps, red; sinica, deep crimson; and sulphurea perfecta, yellowish, are among the best. Although the greenish yellow fruits are usually thrown away when they fall, they may be made use of in a similar way to the fruits of the common Quince. The fact that *Cydonia japonica* forms a good hedge plant in some places does not appear to be generally recognised, but where an out-of-the-way hedge plant is required, many worse things might be selected.

C. Maulei.—This is another Japanese species which differs from the last-named by its dwarfer habit, rather smaller flowers and golden, fragrant fruit. Mature plants are rarely more than $2\frac{1}{2}$ feet high and $3\frac{1}{2}$ feet through. They are made up of numerous thin branches, on which the brick red flowers are borne with the greatest freedom. The fruits are deliciously fragrant, and are said to be the best of all the Quinces for making into jelly. The variety *alba* has whitish flowers, and the flowers of *atrosanguinea* and *superba* are of a rich, deep red hue. The last two varieties are specially worthy of note. *C. Maulei* is very hardy, and thrives as a bush in the North of England. It rarely fails to produce a profusion of blossoms.

C. sinensis is sometimes called the Chinese Quince. It is the most tender of all the kinds, and requires wall culture in most parts of the country. Growing into a large bush or small tree, it is identified by its large, oval leaves and solitary pink flowers, which are about one and a-half inches across. The fruits are very large, oval, and yellowish in colour. Good specimens may be 5 inches to 6 inches long and 3 inches to 4 inches in diameter.

C. vulgaris is too well known to require more than passing notice. Two well-marked kinds are found, one which bears Apple-shaped fruits and the other Pear-shaped fruits. In other respects the trees are identical. The fruits are very fragrant when ripe, and are used for flavouring purposes and for making into jelly. The native country to which the tree belongs is not known, but it is widely cultivated through Europe and other places. D.

ANEMONE BLANDA SCYTHICA. A DELIGHTFUL PLANT FOR ROCK GARDEN OR SUNNY BORDER.

products formed a considerable portion of the exhibits, and at their close went far towards the enrichment of the museums at Kew. It was in 1886 that *Fabiana imbricata* was introduced to notice in this country as a medicinal plant under the name of "Piche," the leaves having the reputation of possessing diuretic properties, and being useful in kidney affections, sciatica, rheumatic neuralgia and lumbago.

As is well known, the plant is a native of Chili, Peru and the Argentine, and belongs to the Natural Order Solanaceæ, though from general appearance an ordinary observer would classify it with the Heaths (*Erica*). Considering that it was introduced to cultivation in this country so long ago as 1838, it is somewhat strange that one does not see it in gardens more frequently. Its spikes of pure white funnel-like flowers, borne in great profusion, together with the early season of flowering and the length of time it keeps in flower, are all strong recommendations for its more general cultivation, besides which the plant grows

properties, the various kinds cannot be considered of sufficient importance to include among valuable fruiting plants. Fortunately, however, they have an asset which warrants them a prominent position in the garden; therefore they are planted for this reason, and the fruit comes in as an extra product. The asset to which allusion is made is their free-flowering qualities and showy flowers, this being especially noticeable with the bush kinds. Altogether five species may be obtained. These are known under the generic name of *Cydonia*, although some people prefer to follow Linnæus and include them in the *Pyrus* family.

The cultivation of the Quinces offers no difficulties, except in the case of one species, which is not sufficiently hardy for outdoor culture in some parts of the South of England, and has to be provided with a position against a warm wall. The common Quince has been included in orchards in this country from an early date, and is well known as a small, round-headed Apple-like tree.

VIBURNUM PLICATUM.

FEW, if any, readers of THE GARDEN will dispute the assertion that this Japanese shrub is one of the six best deciduous flowering shrubs cultivated in our gardens. By botanists *V. plicatum* is classed as a form or variety of *V. tomentosum*, of which it is said to be the sterile form, though for garden purposes the two shrubs are quite distinct. The average height is from 4 feet to 6 feet or more. In most gardens it is quite hardy, though in the extreme North the protection of a wall is sometimes found desirable, while even in other parts it is worth attention, should wall space be ample, as it is such a delightful subject when in bloom. The flowering season is late May and early June, when the white clusters of flowers almost hide the foliage. These trusses or clusters are about three inches across, in shape resembling a slightly flattened ball. Perhaps the best effect is obtained by massing *Viburnum plicatum* along the front of a fairly wide shrubby border, or in a large bed with a background of tall shrubs or trees a short distance away. This and other members of the *Viburnum* family delight in a fairly rich loamy soil with no lack of moisture at the root.

FLOWER GARDEN.

SWEET PEA NOTES.

The Great Show.—On Tuesday and Wednesday of next week, the ninth and tenth days of the month, the National Sweet Pea Society will hold its twelfth exhibition, and it is anticipated by the powers that be that it will be superior in all respects to any of its predecessors. It is notable that the authorities of all annual institutions such as this invariably expect to advance, and if the meeting should fall a little short in some particular aspect, an excellent reason, over which no human being could possibly have control, is immediately forthcoming. This is just as it should be, since optimism is essential to success. The prospects of the show are indisputably good, and it is safe to prophesy that thousands of superb flowers will be exhibited, and that the competition in most of the classes will be keen. Let us hope that the tendency to coarseness which has crept into some of the exhibits in recent years will be conspicuous by its absence, and that if there are any such flowers shown, the judges will be down upon them like the proverbial "cartload of bricks." There was some coarseness at the "International," but it did not assist the exhibitors in the smallest degree, for the simple reason that the judges chosen for that great occasion were all for the perfect Sweet Pea.

Provincial Shows.—At all the horticultural gatherings in the provinces at the present time Sweet Peas play a part of considerable importance, and classes for them are numerous and have handsome trophies and valuable money prizes

allocated to them. Visitors to these shows look eagerly for the Sweet Peas, and criticise flowers with a keenness which proves conclusively the hold the flower now has on the public mind. Even at the smallest shows, designed and maintained practically for the cottage growers, classes are provided for the Queen of Annuals, and invariably the competition is strong, though in many instances the blooms do not attain to the standard of a "National." However, the interest is there, and the quality will undoubtedly steadily improve.

Watering.—In most gardens the plants will now demand immense supplies of water; but the fact must never be overlooked that it is easily

admirably grown that they possess the power to respond when called upon in this way.

Feeding.—Amateurs, generally speaking, require no encouragement to feed their plants; on the contrary, one often experiences the utmost difficulty in persuading them that it is exceedingly easy to overdo it. It is no uncommon thing to find a man who is convinced that manure is of infinitely more importance than cultivation, and that it is the simplest thing in the world to make a magnificent plant out of a wretchedly-grown apology by the use of special foods. Never were there greater errors. Those who would have the finest Sweet Peas must rely mainly upon mechanical cultivation of the soil. That feeding will restore a

plant from bad to good health, or make a weakling into a strong and handsome giant, is equally fallacious, and the sooner the facts are universally accepted, the earlier we shall see Sweet Peas splendidly grown in every garden in the country. By all means feed with a variety of suitable foods, but before doing so establish such a foundation as will ensure their perfect assimilation. Whatever is given must be on the weak side, and it must always be applied when the ground is pleasantly moist. These things have been said before, but they will bear repetition. HORACE J. WRIGHT.

NOTES ON THE POET'S NARCISSUS.

JUDGING from letters I sometimes receive, there is a growing feeling among those who are most interested in this section of the *Narcissus* family that a great many—too many—varieties are now on the market, and that not a few are so similar to one another that they ought to be bracketed together as "too-much-alike" varieties, as is done in the case of the Sweet Pea. I sympathise very much with my correspondents. Poets as we have them to-day are bewildering, and to be able to select the best for the purposes of the show-table and the best for the purposes of a garden is a task very much beyond my powers. I used to think the differences between florists' Tulips were hard to detect; but I am now beginning to think that it is child's play to differentiate a Mabel from a Mrs. Collier compared with what it is to tell a Comus from a Spencer, and similarly with many others. I do not think I would have any difficulty if I went through my note-books of the past few years to make out a list of at least a hundred varieties; and as I think of this I wonder how many of them our greatest Poeticus experts could name correctly. I am asked to make a selection of some of the best, and also to say which have all-red eyes and which are "rimmed." To answer this last question first, I append a list of a certain number of the best known, and I have divided them into three groups—(1) the all-red solid eye, (2) the suffused red eye and (3) the rimmed eye. With but one or two exceptions the classification is the

A PROFUSELY-FLOWERED BUSH OF *VIBURNUM TOMENTOSUM* *PLICATUM*.

possible to give too much, and thus do far more harm than good. Efficient mulchings reduce the necessity for watering, and if material suitable for the purpose is not at command, the soil itself should be made to serve by incessant shallow hoeing. The hard water which most of us are forced to use is best poured into grips running down each side of the lines, these being filled as many times as may be deemed necessary or desirable. Occasional vigorous hosings during the evening will still do decided good, especially when they are given after intensely hot, sunny days or when a drying wind has been blowing. The length and strength of the stems improve with this treatment, provided, of course, that the plants have been so

result of my own observation, and it is not based on catalogue descriptions. The first group contains The Bride, Chaucer, Lyceidas, Bard of Avon, Dresden, Acme, Poetarum and Sidney; the second, Muriel, Kestrel, Socrates, Virgil, Ovid, Epic, Ibis, Laura, St. George, Mougli, Biarritz and Horace; the third, Laureate, Walt Whitman, Mistress Prue, White Standard, Comus, Kingsley, Symphony, George Herbert, Tom Hood, Millie Price, Homer, Lullaby, Rhymster, Oliver Goldsmith, Dante, Rudyard Kipling, Jack Point, Carol, Hildegarde, Tennyson, Sonata, Coronation, Herrick, Cæsar, Almira, Ben Jonson, Minerva, John Ruskin, White Elephant, Timon, Sarchedon, Matthew Arnold, Glory and Cassandra. Out of all these, which are the best? I cannot, I fear, offer a selection; I can only say that I like the following very much indeed, and I would not like to be without them: Cassandra, Horace, Kestrel, Kingsley, Acme, Comus, Tom Hood and Virgil. My own practice is to grow a good many varieties, and then at show-time cut those which are in condition. Different years suit different varieties, and, again, an early or a late season makes a great difference in what will be at their best about the date of the exhibition. Hence this should be provided for. Lastly, before purchasing one should find out which are early and which are late. There will be quite a week or ten days' difference in the times of Chaucer and Hildegarde opening. This latter, by the way, I would certainly include in my list if I wanted a late one and was prepared to pay £5 for it. There are others I would add if money was no object and if they were in commerce, such as Sarchedon, Socrates and Snow King. JOSEPH JACOB.

SWEET PEA MRS. ANDREW IRELAND.

[See Coloured Cover.]

THERE are some few people who grow Sweet Peas exclusively for exhibition, still more who cultivate them for exhibition and garden adornment, and many thousands who have them for the latter purpose alone. It is a general idea that Sweet Peas are all much of a muchness, and that a variety suitable for show purposes is equally good for the garden. This, however, is not invariably the case. When a variety is seen on every stand and ranks with the best in vigour, strength of constitution and floriferousness, it must be watched, and it will assuredly be grown. Of such as these is Mrs. Andrew Ireland. I should unhesitatingly include it among the three foremost varieties for gardens. When one visits a trial of a hundred or more Sweet Peas, Mrs. Andrew Ireland will be conspicuous from wherever one stands, for its beautiful bicolor blooms literally smother the plants. On stands that show it may not be absolutely indispensable, but it lends that variety and helps other colours in a manner which make it exceedingly valuable.

H. J. W.

THE WHITE GERMAN CATCHFLY. (LYCHNIS VISCARIA ALBA.)

THE ordinary form of the German Catchfly, with rose-coloured flowers, is a native of various parts of Europe, and is a comparatively rare plant in this country. For several years past gardeners have been delighted with the double form known as *Lychnis Viscaria splendens*, which is undoubtedly the finest garden plant of the group. The white variety now under notice is, however, very lovely when compared with the others. White varieties are usually looked upon as somewhat inferior to the types, but when planted in close proximity to them they are seen under the best conditions. This, then, I consider is the proper and right way

A FINE GROUP OF THE NOBLE EREMURI.

of using a white variety—by placing it alongside some of the dark forms, whether they are single or double. Another excellent way of showing it to advantage is to plant a large clump, group, or bed to form a large mass.

As a garden plant it is undoubtedly most at home in the rock garden, on account of its dwarf habit and short leaves, which are likely to get injured if planted in the ordinary herbaceous border when digging-time arrives. The stems generally grow from 9 inches to 12 inches high, and flowering, as it usually does, at the end of May and the beginning of June, the plant can be looked upon for early summer effect. Among the rocks a naturally-drained soil is almost certain, and the plant will be

happy in this position during the winter. It is perfectly hardy, although sometimes it will suffer during the dull months in the neighbourhood of large and smoky towns owing to the sooty deposit on the foliage, which holds the wet and filth brought down by rains. A good plantsman can get as many plants as he wishes by carefully lifting a large clump and separating each crown with a portion of root if possible. In most cases, however, each crown would have a few roots attached if carefully separated by hand and knife occasionally to make sure of separating the crowns without breaking them. These young pieces should be potted up in the spring. After the plants have ceased flowering they can be put separately into small pots and potted on into larger ones as soon as they are rooted to encourage the crowns to make good flowering clumps for another year. The very small plants may be wintered in a cold frame; this will prevent slugs from destroying them before the growth commences in spring. A. C.

THE EREMURI.

THESE plants constitute a group of the noblest hardy herbaceous perennials, which, by reason of their imposing grandeur, are absolutely unique. They belong to the Lily Order, and come to our gardens from Northern India, Persia, Central Asia and other like parts; hence they are entirely fitted for cultivation in these islands. Hitherto the plants have been grown more or less as isolated examples, though at the present time there are not wanting evidences of that type of grouping which is calculated to display them to much better advantage. In all probability, perhaps the most effective way of dealing with the plants would be to provide them with a thin groundwork of shrubs, from which in early summer the giant inflorescences might issue. In this way these Eremuri would receive protection in spring for the leaves and the then coming spike of flowers. In any companionship of this kind, however, care should be exercised that the noble group we have in mind should have ample space, owing to the nearly horizontal spread or radiating character of their roots. Culturally, at the present time every attention should be given to water-

ing and to liquid manure to encourage the formation of crowns, on which the good flowering another year so much depends. During the past few weeks, both at the great International Show at Chelsea and at Vincent Square, visitors have had an opportunity of seeing these Eremuri in great numbers, though more particularly the forms of *E. robustus*, *E. himalaicus* and *E. Warei*, which are bluish pink, white, and pale orange flowered respectively. The first two named appear in the above illustration, the former, attaining occasionally a height of 10 feet or 12 feet. At a more seasonable time for planting I hope to deal with the group in fuller detail. E. H. JENKINS.

ROYAL HORTICULTURAL SOCIETY'S SUMMER SHOW.

AFTER a lapse of two years, this important exhibition was once again held in the beautiful and spacious grounds of Holland House, Kensington, on Tuesday, Wednesday and Thursday last.

The show proved to be a great success, and the quality of the exhibits has never been excelled. Hardy plants and alpiners were the outstanding features. The water and rock gardens, arranged in different styles, were tastefully designed and carried out. Sweet Peas, Roses, Carnations, pot fruits, Orchids and Ferns were alike well represented. To the Rev. W. Wilks (secretary of the society), Mr. S. T. Wright (superintendent of the show), Mr. Frank Reader and Mr. Plowman we tender our thanks for services freely rendered in enabling us to report this admirable show. Unfortunately, the weather was threatening on the morning of the opening day, rain falling for the greater part of the afternoon.

HARDY PLANTS AND ALPINES.

These were as numerous and as effectively displayed as ever, and in some instances a few plants—notably the Eremuri, which under canvas do not give of the best of their good attributes—were not seen so well as in the open, the majority, because of the coolness and sombreness of the day, were not only seen to good advantage, but were capable of being viewed in comfort.

In No. 1 Tent, Messrs. Wallace and Co., Colchester, had one of their well-known characteristic groups, an arrangement of an Old English terrace and wall and water garden, adapted to modern times. Of its kind it was both ideal and convincing, without many of the extravagances of the exhibition arena—just that kind of thing that any good garden might reasonably contain. The flower-border portion, viewed from the upper terrace, as it were, was particularly effective and good, the height of a yard or more assisting the display materially. In this were seen masses of such Eremuri as Sir Michael, Olga, Shelford, Bungei and such distinctive hybrids of E. Olga as Peach Blossom and Rosy Morn, both of which are exceedingly delicate in colour. *Lilium myriophyllum*, Jenny Hanson Poppy, *Lychnis chalconica*, *Lilium auratum rubrovittatum*, with the "Gem" class of Pentstemons, were among important groups. A further feature was the raised terrace garden, below which came a bordering of Ferns in apparent shade, while again beyond this was seen a quiet, restfully-disposed water garden, grassed to the water's edge, and associated with all that was best and most agreeable with this phase of gardening. Hence it will be seen that the exhibit was of embracing character—indeed, a series—into which many phases entered, the whole being well conceived and perfectly carried out. The Japanese Irises and Astilbes at the margin were arranged in particularly fine groups, and were singularly good and effective. As the outcome of three days' work the result was excellent.

Messrs. W. Cutbush and Sons, Highgate, N., arranged a rather sumptuous group, the central

feature of which was a water garden rendered conspicuous by a free planting of Water Lilies and superb colonies of *Iris lævigata*. Phoriums and Astilbes occupied notable positions, while such things as *Lilium superbum*, *Thalictrum dipterocarpum*, *Darlingtonia*, *Sarracenia* and the like appeared in suitable places. In and around were arranged groups of early Gladioli, *Lilium giganteum*, *Meconopsis Wallichii* and other good and notable plants. The group was in excellent taste and well finished off.

Mr. Maurice Prichard, Christchurch, had a delightfully conceived and arranged rock garden, albeit the newness of the Purbeck limestone employed was rather opposed to complete success. Such things, however, are more or less inseparable from the exhibition tent, and in this instance were quite overshadowed by the great variety of plants introduced, by their choiceness and, not least, by the deftness and neatness of their colonised arrangement. In this way were seen delightful groups of *Hypericum empetrifolium*, *Campanulas pulla* and *puloides*, *Ruta patavina* (yellow), *Cytisus schipkaensis*, *Ranunculus bilobus*, *Ourisia coccinea*, *Wahlenbergia vincaeflora* and the lovely red and crimson single-flowered *Dianthus E. T. Anderton*. Either side of the rock garden was flanked by bolder herbaceous things, a conspicuous group being formed of *Lavatera* (*Malva*) *Olbia*, whose pink flowers, 3 inches across, are a great charm. Great flowering branches of *Coriaria japonica* displayed this most effective shrub to advantage. It is one of the most ornamental plants we know.

Messrs. George Jackman and Son, Woking, had an extensive grouping of the best herbaceous things, Lilies, Delphiniums, *Verbascums*, *Gaillardias*, *Geums*, *Phloxes* and the like all entering freely into a particularly fine display.

Messrs. Russell, Earl's Court Road, W., arranged rockwork outside No. 1 Tent with succulent and hardy plants generally.

In the open Messrs. Carter and Co., Raynes Park, arranged a Japanese garden, the great feature of which were the magnificent groups of *Iris lævigata*, which were everywhere in the greatest profusion. In colours of white, rose, purple, violet and many other shades, the plants were fascinating in the extreme, while around were Lilies, Bamboos, Acers and shrubs, *Funkias* and the like, everything everywhere Japanese to be in keeping with the general idea of the arrangement. The water portion was most effectively and naturally done, and, without obtrusiveness, constituted a most enjoyable whole.

Mr. G. Reuthe, Keston, Kent, arranged a rockwork exhibit on tabling, on which were seen many interesting alpine and other plants. *Acantholimon venustum*, *Abelia floribunda*, *Silene acaulis alba*, *Gypsophila prostrata rosea*, *Campanula raddeana*, *Saxifraga cochlearis*, *Epilobium obcordatum*, *Sedum sulphureum*, *Allium pedemontanum*, *Geranium Lowii*, *Patrinia palmata* (with yellow flowers) and *Campanula mirabilis* were among the more delightful things. A fine specimen of *Desfontainea spinosa* was also noted.

Messrs. Piper and Sons, Barnes, had a capital rockwork arrangement in conjunction with water

and Japanese Irises, the whole being well arranged with many suitable groups of plants.

Messrs. John Forbes, Hawick, Limited, had a remarkably good display of *Violas*, *Pentstemons*, *Pyrethrums* and *Phloxes* in the open, each group in its way containing a large number of good varieties. The *Phloxes* were particularly good, and of these we noted *Tapis Blanc*, *Bella Forbes* (pink) and *Mrs. Oliver* (pink and white). The *Pentstemons* were superb: we have never before, indeed, seen such excellence of culture or size of flowers as these contained in any Holland Park Show. *Thomas Hay* (scarlet and white), *Lady Love* (pure white), *Marquis of Linlithgow* (purple and white, very charming) and *Mrs. Mitchie* (scarlet and white throat) were among the best in a really grand lot.

Mr. Clarence Elliott, Stevenage, displayed on a table of rockwork some really grand masses of alpine flowers, notably the fine blue *Campanula Miss Willmott*, which is perhaps one of the best of recent additions to these plants. It was a most effective picture in a setting which included *C. pulloides*, *Oxalis enneaphylla*, *Coronilla Cappadocia* (yellow) and some others.

Messrs. Barr and Sons, Covent Garden, W.C., had a most effective grouping of *Phloxes*, alpiners, English Irises and other good herbaceous subjects. *Salvia virgata nemorosa* (in purple and red) was singularly striking and good, a great gain effectively when seen in a mass as exhibited. It is almost unique. *Larkspurs*, *Lilium candidum*, *Campanula pusilla* (in wonderful array) and many annuals added greatly to the charm of the group as a whole. In the centre of the group was seen a prettily-conceived rock garden suitably and agreeably planted on all sides. *Campanula Hendersonii* was quite a striking plant, and is rarely seen in such excellence. The group, which included a choice lot of Japanese dwarfed trees, extended throughout the entire side of Tent No. 3.

On two sides of Tent No. 4 Messrs. George Bunyard and Co., Maidstone, exhibited splendid displays of hardy flowers. Lilies and Delphiniums being particularly good and in fine groups. The more conspicuous were *Alake*, *Queen Mary* (blue and white), *Rev. E. Lascelles* (the glory of the semi-doubles) and *Primrose*. The *Double White Rocket*, *Pentstemon Southgate Gem* and a series of the new *Astilbes Venus*, *Ceres* and *Rose Pearl* were quite good.

Mr. Howard H. Crane, Highgate, N., had some eighty or more pans of *Violas* delightfully arranged, showing to advantage these most precious of hardy bedding flowers. *Moseley Perfection* (yellow), *Royal Sovereign*, *Lady Knox* (primrose), *J. B. Riding* (rosy red), *Maggie Mott* and *Hugh Reid* (a fancy sort) were among the best in a really superb gathering. Some charming vases of the more miniature-growing *Violettas* were also noted.

Messrs. W. and J. Brown, Stamford, exhibited fine masses of *Gaillardias*, in which the self yellow *Lady Rolleston* found a place. *Thalictrum Delavayi* and *Ostrowskia magnifica* were also noteworthy and uncommon.

Messrs. R. H. Bath, Limited, Wisbech, had a rich display of *Delphiniums*, *Tribouia* (metallic

blue and mauve), Lord Charles Beresford (deep blue, white centre), Perle Bleu (semi-double, very distinct), and King of Delphiniums being among the finer sorts. Superb vases of Carnations were also seen in plenty.

Messrs. G. Bolton and Sons, Buntingford, Herts, had a mixed group of hardy flowers which contained *Campanula luteosa*, presumably a semi-double variety of *C. persicifolia*.

Messrs. Carter Page and Co., London Wall, showed a remarkable assortment of *Violas* in pans, some 300 of these making a really grand show. Bronze King, Redbraes Yellow, Purple Bedder, J. B. Riding and Virgin White were very beautiful.

Mr. G. Reuthe, Keston, Kent, displayed in No. 10 Tent a showy lot of hardy herbaceous plants, with flowering shrubs and alpinas, Lilies, Larkspurs and the more seasonable flowers being arranged in plenty.

Messrs. G. Mallett and Co., Cheddar, arranged a group of herbaceous things, in which the dominant features were *Lilium candidum*, *Salvia nemorosa virgata* and *Phlox omniflora* Snowden, a most effective variety of the early-flowering race. *Stachys grandiflora* was likewise a notable plant, good and distinct.

Early *Gladioli* and *Sparaxis* were the chief features of an exhibit from Messrs. Lilley, Guernsey, the group being most attractively arranged with Grasses. *Brodiaea laxa* in rich violet was also very beautiful.

Messrs. Paul and Son, Old Nurseries, Cheshunt, arranged a group of Phloxes, Heucheras, *Alstroemerias*, *Campanulas* and other good hardy flowers of the moment.

Mr. B. Ladhams, Southampton, had a remarkable display of *Gaillardias*, Superb and Sulphur Gem being perhaps the more conspicuous and distinct. *Salvia superba* (*S. turkestanica* × *S. Selarea*) is a most handsome plant. Pinks, too, were very charming and beautiful. The mass of *Scabiosa caucasica* was very fine.

Messrs. Robert Veitch and Co., Exeter, had some exceptional things in *Lonicera Hildebrandtii*, *Abutilon vitifolium album*, *Cyrilla racemiflora*, *Plagiatanbus Lyallii*, *Destontainia spinosa* and the rarely-seen *Notospartium Carmichaeliæ*, whose rose-coloured flowers on Rush-like stems are most charming.

Mr. Leslie Greening, Richmond Hill, exhibited a small rock garden with pool.

Hardy hybrid Phloxes, raised between *P. canadensis* and *P. decussata*, were shown by M. G. Arends, Ronsdorf; an interesting gap-filling race in which there are future possibilities.

A rock garden in red sandstone, arranged with Ferns and alpinas, came from Messrs. Fells and Sons, Hitchin, Herts. *Primulas* and *Thymes* were very charming.

Messrs. Gunn and Son, Birmingham, arranged basket groups of their *Viola cornuta* forms, such as alba, purpurea, and Lilac Queen. Some fine stems of *Lilium auratum* were well shown.

Messrs. Whitelegg and Page, Chislehurst, displayed an extensive group of hardy things, *Gladioli*, Larkspurs, Water Lilies, *Geums*, *Heucheras* and other showy plants.

Mr. James Box, Lindfield, arranged a particularly showy group of *Eremuri*, *Inula royleana*, *Cimicifuga racemosa*, English Irises, *Delphiniums*, the early *Gladioli*, Phloxes, *Sidalcea Listeri* and other plants.

Messrs. G. and A. Clark, Limited, Dover, had a particularly fine group of things—*Pyrethrums*,

Salvias, *Alstroemerias*, *Lilium candidum* (very fine) and the lovely *Gilia coronopifolia*, whose scarlet spikes were very fine. *Eremuri*, *Centaurea ruthenica*, *Origanum*, *Dictamnus* and *Delphiniums* were also good.

Messrs. Phillips and Taylor, Braeknell, Berks, had a variety of hardy plants associated with a Lily pond and fine banks of *Delphiniums* and other plants.

An exhibit of *Delphiniums* of considerable extent, if quite devoid of artistic merit, was arranged by Messrs. Kelway and Son, Langport, quite a large number of varieties in moderately-grown spikes being well displayed.

Mr. Reginald Prichard, West Moors, Wimborne, had a most interesting lot of things, chiefly alpinas, of which *Pentstemon White Newbury Gem*, *Saxifraga diversifolia*, *Wahlenbergia vineiflora*, *W. saxicola*, *Dianthus Jubatus* and *Pentstemon Californian Blue Gem* were a few.

Messrs. W. Godfrey and Son, Exmouth, Devon, had a sumptuous group of *Canterbury Bells*, the great cup-and-saucer flowers in blue, pink and white defying description; an admirable display of an easily-grown and popular plant.

Mr. Amos Perry, Hardy Plant Farms, Enfield, displayed a lovely lot of *Delphiniums*, gorgeous banks of blue, violet and purple in many shades. Duke of Connaught (deep blue and white), Carnegie (metallic blue and mauve), Blue Fendre, Julia, La France and Rev. E. Lascelles were among the most imposing and beautiful. In another group Mr. Perry showed massed banks of Pinks, Phloxes, Lilies, *Veronica spicata alba*, and *Bletia hyacinthina*. Hardy Ferns and Water Lilies, all delightfully displayed, occurred as an extension of a group overwhelming in fascination, in beauty and in grace. *Lavandula nana atropurpurea* and L. Miss Jekyll's variety were also good. *Dianthus Painted Lady* and *Prunella webbiana rosea* were charming plants in this group. The exhibit from Mr. Perry occupied upwards of two thousand five hundred square feet, and contained many plants of merit.

A great and glorious bank of Phloxes came from Messrs. Gunn and Sons, Birmingham, the rich masses of colour absolutely defying description. Baron von Dedem (scarlet), Elizabeth Campbell (pink), Flora (pink and white), Le Mahdi (deepest violet) and George A. Stroehlein (scarlet) were grand. One of the finest displays of Phloxes ever seen.

MISCELLANEOUS STOVE AND GREENHOUSE PLANTS.

A very charming group of flowering plants was set up by Messrs. W. Cutbush and Sons, Highgate, London, N. *Polyantha Roses*, such as Eileen Low, Orleans Rose, Jessie, Mme. Norbert Levavasseur and several other good things were beautifully grouped. Very striking were the Carnations in this display. Lady Coventry (rich and striking), Lord Rothschild, Queen Mary, White Perfection and King Arthur were all noteworthy. Crotons, Palms and Ferns added very materially to the effect of this group.

"Magnificent" aptly describes the gorgeous group of stove and greenhouse plants arranged by Messrs. J. Veitch and Sons, Limited, Chelsea, S.W. This group embraced grand examples of Crotons and other choice foliage plants, and in conjunction with flowering subjects, such as Orchids in variety, *Solanum Wendlandii*, *Cannas*, *Clianthus Dampieri* and *Santpaulia ionantha*, made a really magnificent display. Of the foliage plants worthy of mention,

the following were of a high order of merit: *Anthurium Hookeriæ*, *Polypodium glaucum crispum*, *Araucaria Silver Star*, *Cyanophyllum magnificum*, *Croton Resplendent*, *C. Thomsonii*, *C. B. Comte*, *C. Flamingo* and *Alocasia argyrea*.

Messrs. J. Hill and Son, Barrowfield Nurseries, Lower Edmonton, had a superb group of Ferns, in which there were many superb specimen plants. This group was so large and comprehensive that it occupied one-half of the centre of the Large Tent and faced all round. Noteworthy examples were *Platyceerium Veitchii*, *Lomaria gibba*, *Gleichenia Mendelii*, *Nephrolepis exaltata superba*, *Davallia Fijiensis robusta*, *Polypodium Knightæ*, *Nephrolepis Marshallii compacta*, and an immense array of beautiful plants the majority of which deserve mention. The disposition of the various subjects in this group was very good.

A superb exhibit of Ferns was staged by Messrs. H. B. May and Sons, The Nurseries, Upper Edmonton. The grouping in this case was charmingly carried out, and the effect was distinctly artistic and pleasing. *Adiantum farleyense gloriosum*, *Polypodium Knightæ*, *Lastrea patens variety Mayii*, the dainty little *Nothochloena rufo* and *Gymnogramma schizophylla superba* were among a host of most beautiful things that should please the Fern-lover.

A pretty group of *Araucaria Silver Star* was shown from Messrs. Thomas Rochford and Sons, Turnford Hall Nurseries, Broxbourne, Herts. This is a charming acquisition, and should be much valued by those who use this subject for conservatory embellishment.

A group of foliage plants from Mr. W. A. Manda, South Orange, New Jersey, U.S.A., and St. Albans, Herts, had a few choice plants staged therein; a notable example was *Polypodium mandaianum*, which received a first-class certificate. This is a beautiful plant, and was exhibited in splendid condition.

Zonal *Pelargoniums* in wondrous variety were shown in handsome bunches by Messrs. Carter Page and Co., London Wall, E.C. The colours were vivid and striking, and the individual pips very large. George Cooke, Andrew Lang, Mrs. Brown-Potter, Dublin and Princess of Wales were all striking.

Mr. H. J. Jones's Nurseries, Limited, Lewisham, S.E., set up one of their famous groups of Zonal *Pelargoniums* growing in pots. We have never seen anything to equal this fine exhibit of *Geraniums*, as the quality throughout was so good. Many seedlings from Paul Crampel were in evidence, and this gives a very good indication of their worth. St. Louis, H. J. Jones, Alf Simpson, Mrs. Tom White, Carmania, Will E. Newman and Freddie were noteworthy. A capital collection of Ivy-leaved *Pelargoniums* was also shown, embracing such sorts as Her Majesty, Mr. Hawley Gallilee and others.

Double-flowered *Begonias* were well shown, as usual, by Messrs. Blackmore and Langdon, Twerton-on-Avon, Bath. Exquisite aptly describes the quality and beauty of these flowers. The plants were in grand condition, carrying really wonderful blooms. Mrs. Robert Morton (amber), Florence Nightingale (white), William Marshall (brilliant crimson), Irene Tambling (orange) and Miss Ethel Gill (pink) were all magnificent.

Caladiums from Messrs. John Peed and Son, West Norwood, S.E., made an interesting exhibit, although not so large in extent as usual. The grouping left nothing to be desired, and was quite pleasing. Sir Henry Irving, W. E. Gladstone, Triomphe de Combe, King George, Mikado, Lady

Stafford Northcote and Oriflamme were conspicuous, and were a welcome piece of colouring.

Messrs. J. Carter and Co., Raynes Park, S.W., staged a pretty table group of Begonias, Streptocarpus and the primrose-coloured Calla, edged with Adiantums and Panicum variegatum. The effect was pleasing. The Begonias were very good, double-flowered sorts alone being represented. The Streptocarpi were pleasingly diverse in their colourings and markings.

Fuchsias from Messrs. Piper were a somewhat unusual exhibit at these shows. Specimen plants made an excellent background, with standard Fuchsias rising out of a groundwork of small in considerable variety. This exhibit recalled the days when the Fuchsias were so popular. The group was generally regarded as a distinctly good one.

A nice group of stove and greenhouse plants came from Mr. J. Bruckhaus, Twickenham, in which Caladiums, Crotons and Palms were chiefly conspicuous.

A small table group of show and fancy Pelargoniums was staged by Mr. W. Treseder, Cardiff. Lord Bute, Lady Bute, Flora and several others were exhibited.

In a group of plants set up by Messrs. Whitelegg and Page, Chislehurst, Kent, there was a mound of Salmon Paul Crampel Zonal Pelargoniums, which merited attention.

Choice stove and greenhouse plants were displayed in a table group by Mr. L. R. Russell, Richmond, Surrey. Here were to be seen pretty examples of Alocasia, Caladiums, Dracaenas, Anthuriums and many choice subjects too numerous to mention. The grouping was well done considering the circumscribed area.

Messrs. Stuart Low and Co., Bush Hill Park, Enfield, staged a table group of such subjects as the Bottle-Brush Tree, Gerberas, Hydrangeas, Ericas, Pelargoniums, and the new Arancaria Silver Star.

Messrs. H. Cannell and Son, Swanley, Kent, made a grand show. In their group they had represented splendid banks of Cannas, double Begonias, Gloxinias, Zonal and Ivy Pelargoniums, backed by numerous specimens of American Pillar Rose. The Cannas were rich and glorious in their hues, the Begonias of a high order of merit, and the new Salmon Paul Crampel Zonal Pelargonium was grand. Rosebud is a pretty double Begonia.

Mary Countess of Ilchester (gardener, Mr. Dixon), Holland House, had an interesting group of succulents, embracing quite a large number of varieties. There were also several very interesting Cactaceae plants.

The sweet-scented Pelargoniums as shown by the Hon. Vicary Gibbs, Aldenham House, Elstree, Herts (gardener, Mr. E. Beckett), were a pleasing feature of this great show. Here were to be seen these noteworthy plants in almost endless variety. A few worth special mention were Pelargonium crispum maximum, P. Moore's Victory, P. ficifolium odoratum, P. Agnes, P. Purple Unique (well-flowered) and many others equally noteworthy.

ORCHIDS.

J. Gurney Fowler, Esq., Woodford, showed various Selaginellas in good style. Prominent among these were S. Braunii, S. apus (in pyramid form) and S. inaequalifolia. Interspersed among the greenery of the Selaginellas were Orchids, the most noticeable being Odontoglossum armainvillierensis xanthotes and Cattleyas.

Mr. H. A. Tracy, Lily and Orchid Nursery, Twickenham, staged a compact little group of Orchids, including Cattleyas, Odontoglossums, Pleurothallis Scapha and Cypripediums.

Messrs. Charlesworth and Co., Hayward's Heath, had a really magnificent group. Occupying a prominent position were some fine specimens of Phalaenopsis rimestadtiana. Other notable exhibits were Grammangis Ellisii and Epidendrum prismatocarpum. The pretty little Aerides japonicum, which gained its first award at the 1866 Show, and shown as a rare plant at the recent "International," was to be observed, also well-grown plants of Epidendrum vitellinum majus, Oncidioda Cybele, Brassavola digbyana, Laelio-Cattleya Ceres variety Princess Mary, Brasso-Cattleya Leemannia and many others. Oncidium clasianum was an interesting exhibit.

Messrs. Mansell and Hatcher, Limited, Rawdon, Yorkshire, staged a fine exhibit. Cattleya dupreana showed up well. Laelio-Cattleya blechleyensis variety King George and L.-C. Martinetti were very attractive. Among other fine specimens were Miltonias in variety, Cattleyas, Cypripediums, including C. chamberlainianum and C. rothschildianum, Saccolabium Blumei, Odontoglossum williamsianum and many other well-grown Orchids, staged in excellent taste.

Mr. E. V. Low, Haywards' Heath, showed Cattleya Mendelii, C. Myra Teesters and C. Mossiae reineckiana, Laelio-Cattleyas, Cypripedium l'Ansonii and Bulbophyllum Colossus.

Sir Jeremiah Colman, Gatton Park, Reigate (gardener, Mr. J. Collier), put up an interesting exhibit, including Odontoglossums, Cattleyas, Nepenthes and Miltonias. Cypripedium superbiens, Cattleya Mendelii grandiflora, Epidendrum alatum and Odontioda Bradshawia stood out prominently.

E. H. L. Davidson, Esq., Twyford (gardener, Mr. F. Cooper), showed Laelio-Cattleya Endora, L.-C. Cowanii and L.-C. canhamiana. Among others were Cattleya Mossiae Wagnerii, Cattleya thurgoodiana, Odontoglossums and Laelia tenebrosa x L.-C. canhamiana.

Mr. Harry Dixon, Spencer Park Nursery, Wandsworth Common, S.W., staged Odontoglossum Dora, O. Solon, O. laudatum and O. Fascinator. Cattleyas and Odontiodas made up the group.

Messrs. Stuart Low and Co., Bush Hill Park, Enfield, occupied a large portion of the Orchid Tent with a well-staged group. Noticeable among many other fine specimens were Cattleya thurgoodiana Apollo, C. gigas Meteor, C. reineckiana variety Snowflake, and C. Mossiae. Vivid scarlet sprays of Renanthera imschootiana hung out prominently from the group. Oncidium pulvinatum, O. flexuosum, O. Gardenii and O. crispum added to the effect of the whole. Cypripedium niveum and C. bellatulum attracted by their dwarfness. Laelio-Cattleyas, Dendrobiums, Cypripediums, Odontoglossums and Coelogynes were shown in profusion. Acineta Humboldtii, Gongora fuscolutea and Masdevallia simula were among other interesting exhibits. The tiny blooms of the latter peep out of the foliage like pheasants hiding in grass.

Messrs. James Veitch and Sons, Limited, Chelsea, showed a few Orchids in their huge general group. Cypripedium Curtisii, Cattleya Mendelii, Vanda caerulea, Oncidium leucochilum, Laelio-Cattleya Gladiator, Promenaea citrina, Odontioda Thwaitesii and Dendrobium Dearii were among the most striking. Cattleya gaskelliana, C. gigas sanderiana and Disa Luna were well-grown specimens.

ROSES.

Messrs. Stuart Low and Co., Bush Hill Park, Enfield, showed superb blooms of Mildred Grant, Liberty, Killarney, Richmond, Rayon d'Or and the Lyon Rose. The colour of the blooms and the manner of arrangement were all that could be desired.

Messrs. Frank Cant and Co., Braiswick, Colchester, were represented by a very fine collection of Roses, including Lyon Rose, White Maman Cochet and Marquise de Sinety. The single Roses Lady Curzon, Joseph Billard, Hebe's Lip and Gottfried Keller were much admired.

Messrs. William Paul and Son, Limited, Waltham Cross, had a magnificent group of Roses in baskets, interspersed with standards carrying a profusion of bloom. Among the varieties in baskets we were much impressed with Warrior, Château de Clos Vougeot and Mme. Ravary.

The delightful group from Mr. Charles Turner, Slough, was the admiration of all. In the foreground were arranged baskets of such capital varieties as Ulrich Brunner, Geoffrey Henslow (new crimson) and Viscountess Folkestone. The two new ramblers, Coronation (crimson) and Ethel (pink), were shown in grand form.

Mr. George Prince's Roses from Oxford were the acme of perfection both in colour and arrangement. In the centre of this group was a lovely stand of the new bedding Rose, Rayon d'Or, surrounded by equally good stands of Lyon Rose and Juliet, with ramblers in the background.

Messrs. George Bunyard and Co., Maidstone, showed very nice blooms of Juliet, Frau Karl Druschki and Lyon Rose in boxes, with ramblers such as American Pillar, Philadelphia Rambler, Rubin and Queen Alexandra as a background.

Messrs. W. and J. Brown, Stamford and Peterborough, had a beautiful group of fresh blooms, among which we noted Mme. Ravary, Richmond and Mme. M. Soupert.

Messrs. R. H. Bath, Limited, Wisbech, showed fine vases of Rayon d'Or, Beauté de Lyon and Marquise de Sinety, all very well coloured, in a good general collection.

Baskets of Roses were the feature of a very nicely-arranged group staged by Mr. W. Easlea, Danecroft Rosery, Eastwood, Essex. We were well impressed with two new bright little Polyantha Roses raised by the exhibitor, viz., Little Dorrit and Little Nell. The Lyon Rose, Harry Kirk, Duchess of Wellington and Arthur R. Goodwin comprised some of the choicest baskets in a remarkably good collection.

Messrs. Alex. Dickson and Sons, Limited, Hawtmark, Newtownards, County Down, had a superb collection, comprising Lady Ashtown, Lady Pirrie, Alex. Hill Gray, Mrs. Fred Straker, Duchess of Wellington, Theresa, Queen Mary and Duchess of Sutherland.

Messrs. B. R. Cant and Sons, The Old Rose Gardens, Colchester, were particularly strong with such choice novelties as Theresa, Rayon d'Or, Juliet, and a new seedling Hybrid Tea named Sunbeam, of delicate apricot colouring. Rose du Barri, Countess of Gosford and St. Helena were other gems in this admirable collection.

Messrs. G. Bolton and Son, Buntingford, Herts, showed some good vases of Prince de Bulgarie, Mme. Segond-Weber and Gustave Regis among many others.

Messrs. Paul and Son's group of standard and weeping standard Roses from Cheshunt, Herts, was one of the features of the exhibition, and one which we hope to illustrate in our next issue. The

foreground was occupied by baskets and vases of the best Roses in cultivation.

An extensive and gorgeous display of Roses from Messrs. Hobbies, Limited, Dereham, Norfolk, came in for general admiration. The collection seemed to contain almost all Roses worth growing. The new single Pink Pearl and the new semi-double Effective (carmine) were both well shown in this group.

Messrs. G. Jackman and Son, Woking, Surrey, were represented by a first-rate collection of Roses, in which the delicate shades of Duchess of Wellington, Harry Kirk and Mrs. Alfred Tate were conspicuous.

Mr. J. D. Webster, Chichester, showed Roses in variety, together with Sweet Peas, Vallota purpurea and other flowers.

Mr. John Mattock, New Headington, staged a magnificent group of Roses, with a grand display of Marquise de Sinety as a centre-piece.

Messrs. David Russell and Son showed a grand lot of Frau Karl Druschki Roses in boxes and vases.

A really charming display of cut Roses was sent by the Rev. L. C. Chalmers-Hunt, William Rectory, Hitchin.

Messrs. Hugh Dickson, Limited, Royal Nurseries, Belfast, had a very choice and beautifully-arranged table of Roses comprising the best varieties in cultivation. Mme. Melanie Soupert, Lady Pirrie, Leslie Holland and Frank Workman were four good varieties in an excellent collection.

A sport from Dean Hole, known as Duchess of Normandy, a lovely soft yellow with a suspicion of pink, was shown by Mr. Philip le Cornu of Jersey.

Mr. R. C. Notcutt, The Nursery, Woodbridge, had a capital group of Roses containing a representative collection of the best varieties. Mrs. E. J. Holland was particularly fine.

FRUIT.

A magnificent group of fruit trees in pots was set up by Messrs. James Veitch and Sons. The task of reporting this was particularly difficult, owing to the attractiveness of the fruit. Well-grown trees of Peaches in full bearing included Peregrine, Duke of York, Hale's Early, Early Alfred, Early Silver and Royal George. Well-coloured Nectarines on standards comprised Cardinal, Early Rivers and Lord Napier. Heavily-cropped Plums included specimens of Jefferson's, Oullin's Golden, Denniston's Superb and Blue Rock. The Gages were bearing prolifically and were well grown. Standard and wall Gooseberries included Gipsy Queen, May Duke, Keepsake, Lord Audley and Lord Derby. Of the Currants, Fay's Prolific stood out among the reds, and White Versailles was bearing well in the white section.

S. Heilbut, Esq., showed large half-standard Cherries in pots, Late Black Bigarreau being especially well grown, and Nectarines.

The Duke of Rutland (gardener, Mr. W. H. Divers) showed a collection of Strawberries, twelve varieties. All were exceedingly good, the best being Givon's Prolific, Gunton Park, The Countess and Burghley President.

Mrs. Gilliat (gardener, Mr. G. W. Stacey) showed two Fig trees in pots, which were interesting from the fact that they were rooted from cuttings taken from an old tree growing at 4, Crosby Square, E.C. The original was supposed to be the oldest Fig tree in the City of London.

Messrs. George Bunyard and Co. exhibited a selection of beautifully-coloured Apples, Plums, Pears, Peaches and Nectarines in pots. Noticeable

were perfect specimens of Apple James Grieve, Lady Sudeley and Ben's Red. Huge fruits of Marguerite Marillat Pear were prominent. The central position of the group was occupied by a healthy White Marseilles Fig with numerous large fruits.

The King's Acre Nurseries, Limited, Hereford, showed a collection of fruit trees in pots. Prominent among these were Apples Empress Alexander, The Queen, Norfolk Beauty and Beauty of Kent, Peaches, Nectarines, Plums in variety, Black Currants Ogden's Black and Lee's Prolific, and Figs helped to make up an instructive exhibit. A basket of the King's Acre Newberry attracted attention. This fruit is like an enormous Blackberry in appearance.

Messrs. Laxton, Bedford, staged baskets of Strawberries in their inimitable manner. All of the fruits were splendidly shaped and coloured, and the exhibit proved a great attraction. Among the new varieties Laxton's Rival was prominent. The Earl, called by the firm the Midseason Viscountess, is of exquisite flavour. A cross between Waterloo and Royal Sovereign, The Earl is a big addition to the Strawberry world. The fruits are larger than Viscountess. Another new midseason variety was Maincrop. Red Currant Laxton's Perfection is a huge-berried Currant and a prolific cropper.

Messrs. Stuart Low and Co., Bush Hill Park, showed Figs in pots, including Bourjasotte Grise, Black Ischia, Violet Lepore and Brown Turkey. Some good specimens of pot Grapes, including Appley Towers and Muscat of Hungary, made a good background.

OFFICIAL LIST OF AWARDS.

Coronation Challenge Cup.—To Messrs. James Veitch and Sons, Chelsea, for fruit trees in pots and stove plants.

Wigan Challenge Cup.—To Mr. John Mattock, Oxford, for Roses.

Silver Cups.—To Mr. E. H. L. Davidson, 9, Oxford Square, W., for Orchids; Messrs. Mansell and Hatcher, Rawdon, for Orchids; Messrs. Blackmore and Langdon, Bath, for Begonias and Delphiniums; Messrs. G. and A. Clark, Dover, for herbaceous flowers; Messrs. L. R. Russell, Richmond, for stove and ornamental plants, &c.; Sir Randolph Baker, Bart., for Sweet Peas; Messrs. Sutton and Sons, Reading, for Sweet Peas; Messrs. E. W. King and Co., Coggeshall, for Sweet Peas; Messrs. C. Turner, Slough, for Roses; Messrs. B. R. Cant and Sons, Colchester, for Roses; Messrs. F. Cant and Co., Colchester, for Roses; Messrs. A. Dickson and Sons, Newtownards, for Roses; Messrs. Hugh Dickson, Belfast, for Roses; Messrs. H. Burnett, Guernsey, for Carnations; Messrs. T. S. Ware, Limited, Feltham, for Begonias and hardy plants; S. Heilbut, Esq., (gardener, Mr. G. Camp), for fruit trees in pots; Messrs. G. Bunyard and Co., Maidstone; for alpine Roses, fruit trees and herbaceous plants; Messrs. H. J. Jones, Lewisham, for Phlox and Pelargoniums; Messrs. G. Reuthe, Keston, for herbaceous shrubs and alpine; Messrs. J. Piper and Son, Bayswater, for Dutch and water garden; Messrs. J. Veitch and Son, Chelsea, for flowering plants and Bay trees; Messrs. Hobbies, Limited, Dereham, for Roses; Messrs. Jackman and Son, Woking, for Clematis and herbaceous plants; Messrs. J. MacDonald, Harpenden, for Grasses, showing methods of cultivation; and Messrs. J. Peed and Sons, West Norwood, for Caladiums and flowering plants.

MEDALS.

Gold.—To Messrs. Charlesworth and Co., Hayward's Heath, for Orchids; Sir Jeremiah Colman, Bart., V.M.H., Gatton Park, for Orchids; Messrs. William Cutbush and Son, Highgate, for Carnations; Messrs. William Cutbush and Son, Highgate, for group of flowering plants; Messrs. Paul and Son, Cheshunt, for Roses; Messrs. James Veitch and Sons, Chelsea, for fruit trees in pots; Messrs. James Veitch and Sons, Chelsea, for stove and foliage plants and Orchids; Messrs. R. Wallace and Co., Colchester, for an Old English flower garden; Messrs. James Carter and Co., Raynes Park, for Japanese garden and Sweet Peas; Messrs. Dobbie and Co., Edinburgh, for Sweet Peas; Messrs. J. Hill and Son, Lower Edmonton, for Ferns; Messrs. William Paul and Son, Waltham Cross, for Roses; Mr. Amos Perry, Enfield, for herbaceous plants, Ferns, &c.; Messrs. H. B. May and Sons, Upper Edmonton, for Ferns; J. Gurney Fowler, Esq., South Woodford (gardener, Mr. J. Davis), for Selaginellas and Orchids; and Mr. Maurice Pritchard, Christchurch, for herbaceous plants and water garden.

Silver-gilt Hogg.—To Messrs. Laxton Brothers Bedford, for Strawberries.

Silver-gilt Knightian.—To The King's Acre Nurseries, Hereford, for fruit trees in pots; and the Duke of Rutland (gardener, Mr. W. H. Divers) for fruit.

Silver-gilt Flora.—To Messrs. S. Low and Co., Enfield, for Orchids; Messrs. F. A. Haage, Erfurt, for Cacti; Messrs. W. Wells and Co., Merstham, for herbaceous plants; Mr. W. E. Allen, Donmead, for Sweet Peas; Mr. B. E. Bell, Guernsey, for Carnations; Mr. C. Engelmann, Salford Walden, for Carnations; Messrs. Gunn and Sons, Olton, for herbaceous plants; Messrs. Barr and Sons, Covent Garden, for herbaceous plants and pigmy trees; Mr. J. Box, Lindfield, for hardy flowers and Sweet Peas; Mr. C. Elliott, Stevenage, for alpine; Mr. G. Prince, Oxford, for Roses; Messrs. H. Cannell and Sons, Swanley, for miscellaneous group; Messrs. J. Cheal and Sons, Crawley, for garden and herbaceous plants; Mr. E. Lilley, Guernsey, for Gladioli; Mr. R. C. Notcutt, Woodbridge, for herbaceous plants; and Messrs. Carter Page and Co., London Wall, for flowering plants.

Silver-gilt Banksian.—To Messrs. C. W. Breamore, Winchester, for Sweet Peas; Messrs. S. Bide and Sons, Farnham, for Sweet Peas; Messrs. R. Sydenham, Limited, Birmingham, for Sweet Peas; Mr. J. Douglas, Great Bookham, for Carnations; W. W. Gott, Esq., Cornwall, for Carnations; Messrs. G. Lange, Hampton, for Carnations; Messrs. James Carter and Co., Raynes Park, for Begonias; Messrs. W. Fromow and Sons, Chiswick, for Maples; the Hon. Vicary Gibbs, Aldenham House, for Pelargoniums; and the Countess of Ichester, Holland House, for Cacti, &c.

Silver Knightian.—To Messrs. S. Low and Co., Enfield, for Figs; Rev. L. C. Chalmers-Hunt, Hitchin, for Sweet Peas, vegetables and Roses; and The Hallford French Garden, for vegetables.

Silver Flora.—To Mr. S. W. Flory, Tracy's Nursery, Twickenham, for Orchids; Messrs. H. Dixon, Wandsworth, for Orchids; Messrs. J. K. King and Sons, Coggeshall, for Sweet Peas; Messrs. G. Stark and Son, Great Ryburgh, for Sweet Peas; Messrs. J. Box, Lindfield, for herbaceous flowers, &c.; Messrs. H. Lakeman, Thornton Heath, for Carnations; Mr. C. Bick, Hayes, for Carnations; Messrs. R. H. Bath, Limited, Wisbech, for herbaceous plants; Messrs. Godfrey and Son, Exmouth, for herbaceous plants; Mr. H. Hensley, Crawley, for alpine; Messrs. B. Ladham, Limited, Shirley, for hardy herbaceous plants; Messrs. S. Low and Co., Enfield, for Carnations; Messrs. Phillips and Taylor, Bracknell, for herbaceous plants; Messrs. R. Pritchard, West Moors, for alpine; Mr. C. Russell, for rock garden, &c.; Messrs. Whitelegg and Page, Chislehurst, for herbaceous plants, &c.; Mr. J. D. Webster, Chichester, for Sweet Peas, Roses and Carnations; Messrs. J. Forbes, Hawick, Limited, for Phloxes and herbaceous plants; Messrs. G. Gibson and Co., Bedale, for Delphiniums; M. G. Green, Esq., (gardener, Mr. W. White), for Sweet Peas; Mr. A. L. Gwillim, Sidcup, for Begonias; Messrs. Kelway and Son, Langport, for Delphiniums; Mr. W. A. Manda, St. Albans, for foliage plants; Messrs. T. Rochford and Sons, Broxbourne, for Araucarias; Messrs. F. Smith and Co., Woodbridge, for Phloxes and herbaceous plants; Messrs. J. Waterer and Sons, Bagshot, for Yews; Castle's Shipbreaking Company, Millbank, for garden seats; Mr. T. Crowthier, Fulham, for garden ornaments; Messrs. Liberty and Co., Regent Street, for garden pottery; and Sir George Holford, Westonbirt, for Orchids.

Silver Banksian.—To M. Vacherot, France, for new Carnations; Mr. J. Bruckhaus, Twickenham, for Aspidistras; Mr. H. H. Craze, Highgate, for Violas, &c.; Messrs. G. Mallett and Co., Cheddar, for Lilies; Mr. H. C. Pulham, Elsenham, for herbaceous plants; Messrs. H. Freeman, Limited, Sutton, for rustic work; and the Leyton Timber Company, Limited, Leyton, for rustic work.

Bronze Flora.—To Messrs. Bees, Limited, Liverpool, for hardy flowers; Messrs. Carlton White, New Bond Street, for Box trees; Messrs. W. Fells and Son, Hitchin, for rock plants; The Misses Hopkins, Shepperton, for miscellaneous plants; Messrs. Rich and Co., Bath, for hardy flowers; Messrs. V. Slade, Taunton, for cut blooms and plants; and Messrs. Thompson and Charman, Bushey, for perennials.

FLORAL COMMITTEE'S AWARDS.

First-class Certificates.—To Polypodium mandaiianum, from Mr. W. A. Manda; Lilium warleyense, from Miss Willmott, V.M.H.; and Laetia patens Mayii, from Messrs. H. B. May and Son.

Awards of Merit.—To Border Carnation Jean Douglas, from Mr. J. Douglas; Border Carnation John Ridd, from Mr. J. Douglas; Clematis Lady Betty Balfour, from Messrs. Jackman; Astilbe Avalanche, from G. van Waveren; Nephrolepis exaltata Rochfordii, from Messrs. Rochford; Begonia Mrs. Robert Morton, from Messrs. Blackmore and Langdon; Begonia Florence Nightingale, from Messrs. Blackmore and Langdon; Climbing Rose Ethel, from Mr. C. Turner; and Rose Mrs. Charles S. Hunting, from Messrs. Hugh Dickson.

ORCHID COMMITTEE'S AWARDS.

First-class Certificates.—To Miltonia bycama Le Conquerant, from M. Jules Hye de Crom; Cattleya Artemis, from Lieutenant-Colonel Sir George Holford, Westonbirt; and Cattleya dupreana The Dell variety, from Baron Bruno Schröder.

Awards of Merit.—To Brasso-Cattleya Marion, from Messrs J. Veitch; Labio-Cattleya rubens The Kaiser, from Mr. E. H. Davidson; and Cattleya thurgoodiana Apollo, from Messrs. Stuart Low and Co.

* * * Owing to pressure on our space, we are compelled to hold over the reports of Sweet Peas, Carnations and Vegetables until next week.

THE ROSE GARDEN.

THE ROSE DELL AT KEW.

DURING the months of June and July the Rose Dell is one of the features of Kew. It is situated on the eastern side of the Chinese Pagoda, occupying the position of what twenty years ago was a gravel-pit. The main avenue or grass walk is about fifteen feet wide and one hundred yards long, running through the centre of the dell. The garden dips down gradually towards the centre. No formal scheme of planting has been followed, the idea rather being to obtain, as far as possible, a natural appearance. In some instances large bays have been formed, which are usually devoted to one variety, the banks of soil at the sides being supported with large tree stumps or roots. With the aid of the tree stumps the soil in some instances is as much as 3 feet higher than the grass walk. This has a very pleasing effect when viewed from the centre of the garden; the long, arching growths wreathed in blooms are then seen to the best advantage. The Rose Dell owes much of its beauty to the policy of large, bold grouping, one particular feature at the present time being a large planting of Crimson Rambler some twenty yards long and one-third as wide. Means are employed to vary the height of the different groups. Some are allowed to grow in masses with no artificial support; others, notably the wichuraiana hybrids, spread over the ground and clothe the tree stumps. Rough branches freely clothed with snags, and the trunks of young trees of varying height with a foot or more of the branches left on the main stem to support the growths of the Roses, are freely used, resulting, in some instances, in perfect pillars of bloom approaching twenty feet in height.

Mention has been made of the fact that the site of the Rose Dell was previously a gravel-pit; this means poor soil, quite unsuited to the free growth of many Roses. To obtain such gratifying results the very liberal use of top-spit loam and farmyard manure has been necessary, for, without good cultivation, varieties such as Crimson Rambler are seldom satisfactory. On the other hand, it is really surprising how well some of the wichuraiana hybrids—Alberic Barbier and Jersey Beauty, to give two notable instances—thrive in poor soil. A complete list of all the varieties grown would occupy too much space, only those being mentioned which are especially attractive at the present time.

Helène, one of the Polyantha section raised by Lambert, is represented by one or two groups, the clusters of pale rose blooms with yellow-tinted centres being particularly attractive. The plants of this variety are grown in masses, are self-supporting, and about five feet in height. Tea Rambler is allowed to grow in a similar way and is rather taller in habit, the long, arching growth being freely clothed with the salmon pink blooms. Fragrance is a feature of this rambling Rose. For scrambling over rough branches and tree

stumps, the variety Una, with large single white flowers, deserves attention. One of the very best and most distinct varieties of recent introduction is American Pillar. Free and vigorous in growth, the clusters of large single pink blooms with bright yellow stamens in the centre form an effective contrast to the large, deep green leaves. It is a valuable variety which will be grown much more extensively as it becomes known, not only for massing, but for arches, pergolas, pillars and fences. The variety Tausendschön is notably free-flowering. It has large double flowers, deep pink or rose in colour, and fragrant; it belongs to the Polyantha section. Psyche, one of the first hybrids from Crimson Rambler, as growing here is very free with clusters of pale pink blooms. It is difficult to estimate exactly what we owe to the introduction of that charming little white-flowered Rose, Rosa wichuraiana, from Japan. It may almost be said to have revolutionised the growing of rambling and climbing Roses in our gardens; and what

These notes would not be complete without mention of the Dwarf Polyantha varieties Mme. N. Levassieur, White Pet and Jessie, all of which in their respective positions add to the charm and beauty of the Gardens.

THE SCOTCH ROSES.

The various forms of the Scotch Rose (*Rosa spinosissima*) are among the earliest Roses to bloom. The Scotch Rose is a variable species, found in a variety of forms in a wild state. In some places it is found growing wild on commons and other waste land, where it forms a bush 2 feet or so high, the more floriferous plants being those which occupy the poorer soil. In the vicinity of Swansea Bay it has been noted growing on sandbanks among short grass, its stems rising to a height of but 2 inches or 3 inches, while numerous large white blossoms made an effective carpet. Under cultivation it has adapted itself to good soil, and the best examples are those which are given similar

A VIEW IN THE ROSE DELL AT KEW. THE VARIETY IN THE FOREGROUND IS HELENE.

would the Kew Rose Dell be without the huge masses or mounds and pillars of Alberic Barbier, Jersey Beauty, Lady Gay, Dorothy Perkins, White Dorothy Perkins, Edmond Proust, Hiawatha, Elise Robichon, South Orange Perfection, François Fouchard, Paul Transom and Adelaide Mouille?

A rambling or Polyantha variety of moderate growth is Kathleen, with exceedingly attractive single carmine pink blooms with a distinct white eye. For a single variety Kathleen lasts unusually long in flower. There are many more sorts worthy of mention—The Garland, the old favourite Fellenberg, Queen Alexandra, The Dawson, Trier, Flora, Pink Roamer, Mme. d'Arblay, Amadis and the Musk Rose, *Rosa moschata*, which has found its way up nearly to the top of a large Holly tree 30 feet in height, among the green leaves of which appear the large white clusters of the Musk Rose.

ground to that best suited to other kinds of Roses. Of the several named varieties the following are well worth attention: *R. s. altaica*.—This is a stronger plant than the type, for it forms strong, upright branches 3 feet to 4 feet high. Its ivory white flowers are upwards of two inches across. A couple of useful varieties with double yellow flowers are *luteo flore pleno* and *Harrisonii*, while the single golden-flowered variety, *lutea*, is an excellent variety. *Fulgens* is very similar in habit to the type, though its reddish flowers show it to be quite distinct. *Hispida* was at one time thought to be a distinct species, but is now placed as a variety of the Scotch Rose. Its distinguishing features are its strong, upright habit, intensely spiny branches and large pale yellow flowers. *Rubra* has small red flowers; *William IV.*, reddish blooms; while *Stanwell Perpetual*, *Lass o' Gowrie*, *King of Scots*, *Scotia* and *Meg Merrilies* are other good kinds.

THE GREENHOUSE.

WORK AMONG THE CHRYSANTHEMUMS.

MANY cultivators place the plants in the rows at a proper distance apart as they are finally potted. Others group them, placing four rows quite close together, and leaving them thus for several weeks prior to arranging them more openly. The plants do not suffer—in fact, many benefit—if thus placed, providing they are not left so too long. Unless the plants are spaced out in good time they lose many basal leaves through decay and strong winds after the fuller exposure.

Suitable Summer Positions.—In small gardens there is not much choice as to position; the plants must be arranged where there is room for them. In larger gardens the cultivator has a better chance. There is, however, one position which must always be avoided, namely, too near the south or south-

west side of a high building or wall. The strong winds blowing from the south and south-west strike the wall, and then there is a back current blowing down on the plants which is much cooler than a wind blowing from those quarters direct on the plants before striking the wall. An ideal position for plants grown for all purposes—exhibition, conservatory embellishment, or cut flowers—is one right in the open with a rather low, protecting fence on all sides. There are always cold draughts near high trees and buildings, and the result usually in such circumstances is mildewed leaves and immature wood. Place the plants in rows running north and south, so that the foliage and stems will get the maximum amount of sunshine. The tallest plants should be arranged at the north end of each row, and the dwarfier ones at the south. Allow a space of 22 inches between the pots in the case of the tall ones, and 18 inches in that of the dwarf-growing varieties. The rows should be at least 4 feet apart. If there is ample accommodation, 5 feet would be none too much. Stout stakes and wires attached to them will be necessary for the support of the plants. The longest stakes must be driven into the ground at the north end of each row, and the shorter ones at the south end. Put in the strongest stakes at the ends, and the lighter ones, 7 feet apart, between. Usually only one wire is fixed to the stakes, but I prefer two, 15 inches apart at the south or lowest end and 20 inches at the north end of the row. Two wires keep the plants steadier than one, as any necessary side sticks can be made quite secure to them. All plant sticks must be quite smooth and free from knots; then there will be no loss of shoots through their "buckling" on account of the matting getting lodged under any knots. Specimen plants require more room than any others. There must be space for the cultivator to walk all round them as late as the month of September, when each one is nearly full grown.

Watering.—For at least eighteen days after the final potting, water in great bulk will not be needed. There is a considerable quantity of new soil in the large pots, and when this has been moistened through once it retains much moisture for a long

and the Westonbirt variety are also noteworthy. We mention these to show what a wide range of colour there is in one species, and to point out that many, if not all, of these choice gems were originally imported from Colombia. It follows, then, that where the amateur is a sportsman as well as a plantsman, he will purchase newly-imported examples; but my advice is to buy semi-established pieces from a reliable firm, who will guarantee them unflowered so far as this country is concerned. Then, again, where the grower does not care to take a "sporting chance," really good varieties can be bought for a moderate sum; but the amateur will probably be best satisfied if he selects his plants in flower.

Miltonia Roezlii.—This plant closely resembles *M. vexillaria*, except that the foliage is not so wide, while its constitution is not so robust, thus requiring warm-house treatment.

Miltonia bleuana.—A splendid form of this charming hybrid was figured in *THE GARDEN* for June 4, 1910. The parentage is *M. vexillaria* and *M. Roezlii*, and it is fairly intermediate between these two plants; but the hybridiser has so many different forms or the first-named parent to work with that we get various examples of this choice plant.

Cultural Notes.—As *Miltonias* pass out of flower, and for a few weeks onwards, they must be kept on the dry side, but the bulbs ought not to be allowed to shrivel, for although growth will be slow, *Miltonia vexillaria* is never really at rest. When the new shoots show signs of rooting, any repotting may be done, using a mixture of *Osmunda* fibre, good peat, chopped sphagnum moss and partly-decayed Oak leaves in equal parts, the whole to be sifted through a 1-inch meshed sieve and thoroughly mixed before commencing operations. All the fine particles must be removed, and a 6-inch potful of finely-broken crocks may be added to every bushel of the compost with advantage. *Miltonias* are more or less surface-rooting subjects, so fairly deep pans without side boles should be chosen, which can be filled one-third of their depth with drainage. In repotting, press the soil moderately firm, and the surface should be on a level with the rim of the pan. Never overpot, because it is best to give new soil annually, whereby good results can only be obtained. After the operation is completed, arrange the pans upon inverted flower-pots in a shady part of an intermediate house where the night temperature fluctuates between 55° and 60° Fahr., and only give enough water to maintain the surface moist. This, however, can be increased as root action becomes more vigorous, and in the meantime keep the surroundings damp by frequently spraying between the pots, while the paths and underneath the stages must be occasionally sprinkled with water. Both top and bottom ventilation should be given with discretion, always avoiding a strong current of air passing directly over the plants. The most successful growers of *Miltonia vexillaria* try to maintain as equal a temperature as possible throughout the year, and keep their plants quite clean of thrips. This can be partly brought about by lightly spraying overhead whenever the weather is hot, and by dipping them in a weak solution of XL All Liquid Insecticide at intervals of three weeks or directly any insect pest is noticed. Over-potting is perhaps the greatest pitfall in the culture of *Miltonias*, and overwatering, another common error, should be especially guarded against after repotting.

SENTINEL.

A HEDGE OF MULTIFLORA ROSES IN THE ROSE DELL AT KEW.

time. If kept in a medium state of moisture the roots will enter it freely, the progress of the plants will be steady and satisfactory, the leaves will get greener and larger, and the stems will thicken more at their base. AVON.

ORCHID NOTES.

MILTONIA VEXILLARIA AND ITS ALLIES.

The *Miltonia* is a most useful and decorative Orchid, which, if given ordinary attention, will thrive and produce fine pseudo-bulbs that often push up two spikes bearing from three to seven of its broad, flat flowers. These show considerable variation in colour where a quantity of plants are cultivated, but the type usually has lilac rose blooms deepening to dark rose, while the large lip is generally darker than the other parts.

Some plants have almost white flowers, such as the rare *Snowflake*, shown before the Royal Horticultural Society on June 4, 1912, while a few of the highly-prized forms embrace *rubella* G. D. Owen and *Baron Schröder* (two of the best in cultivation), while *splendens* *Queen Alexandra*

GARDENING FOR BEGINNERS.

CULTURAL NOTES ON CANNAS.

THOSE of the readers of *THE GARDEN* who followed the directions given on this page in the issue for March 16 as to the propagation and subsequent treatment of these gorgeous flowers are, no doubt, reaping the benefit of their labours. Many of the plants are now in bloom, and in order to keep up a succession thereof it is very necessary to bear a few points in mind. An important matter is to remember that these Cannas are liberal feeders; hence they should not be starved in pots too small, while the soil should be of a good, lasting nature. Pots from 6 inches to 7 inches in diameter are a very suitable size for single plants, while masses or clumps in pots as large as a pail are very useful for standing on balconies, terraces, or in many other positions. Plants that have flowered well in the greenhouse in 5-inch pots will not give of their best again unless they are stimulated to make further growth. In order to induce them to do this, a good plan is to turn them out of their pots and, without disturbing the roots in any way, to put them into pots of the size above stated, namely, 6 inches to 7 inches in diameter, according to the vigour of the individual plants. The soil may consist of good turfy loam, two parts; well-decayed manure, one part; and a dash of sand. While these Cannas need a liberal supply of water when the pots are well furnished with roots, they do not, of course, require so much for a short time after repotting, that is, until the roots have taken possession of the new soil.

While the advice to put in larger pots for greenhouse decoration refers principally to those that are in 5-inch ones, it may be that they are already established in pots sufficiently large. In this case the necessary stimulant may be applied in the shape of liquid manure or one of the many concentrated plant foods now so popular. Apart from their value in the greenhouse, these Cannas are, from their noble leafage and striking blossoms, very suitable for taking into the dwelling-house occasionally, where, just dropped into an ornamental vase or jardinière, they will be much admired. When intended for this purpose they must be limited to pots of a suitable size for the receptacles in which they are to be placed.

Out of doors a vigorous specimen planted in a lard-tub will, in an angle of the dwelling-house or similar position, prove an object of beauty throughout the summer months, and in winter it may be safely kept in a cellar or any spot where it is safe from frost. In the flower-beds, too, Cannas

are very attractive, both from a foliage and a floral point of view. In some the leafage is of a pronounced bronzy hue, while in others it is of a rich deep green tint. The colour of the flowers also ranges from pale yellow, almost white, to very deep crimson, through various intermediate shades of yellow, amber, orange, terra-cotta, pink, carmine and scarlet. The list of varieties is such an extensive one that in most cases a rigid selection is necessary.

(scarlet and orange) and William Saunders (deep rich scarlet, a very fine flower). The popular name of Indian Shot is applied to the Cannas, owing to the hardness of their seeds, which, report says, have before now been used as shots. From the hardness of the outer coating the seed often fails to germinate if it is sown in the ordinary way. For this reason some recommend that the seeds be filed, but I prefer to soak them for twenty-four hours in water at a temperature of about 110°. They must be sown directly they are taken from the water, and not be allowed to get dry afterwards. So treated and plunged in a gentle bottom-heat they will grow quickly.

THE BEAUTIFUL CANNA J. B. VAN DER SCHOOT.

In looking over a large collection the other day I noted the following as among the very best in their respective colours: J. B. van der Schoot (herewith illustrated, rich golden yellow, dotted with red), Gaekwar of Baroda (golden yellow, with larger crimson spots than the preceding), A. Ortmann (dark velvety purple), Baron de Richter (bright apricot, lighter edge to petals), Frau E. Kracht (rosy salmon), Fürst Weid (deep crimson), King Humbert (bright reddish orange), Meteore (orange scarlet), Niagara (deep scarlet, with heavy gold margin), Ottawa (rosy cerise), Rosea gigantea (rich rose), R. Wallace (canary yellow), Stuttgartia

and a liberal amount of sand incorporated therewith. Then it is made firm and level for the reception of the cuttings. These should be taken off with a sharp knife, and be at once dropped into a bowl of water in order to keep them from flagging. Before insertion they should have one or two of the bottom pair of leaves removed, and then be dibbled firmly into the border prepared for them. They must then be thoroughly watered through a fine rose. The cuttings take root without covering in any way, but in the case of choice kinds it is more satisfactory to cover them with a hand-light or frame. H. P.

HOW TO PROPAGATE PINKS.

FROM a very remote period Pinks have been favourite garden flowers, and to-day they are as popular as ever they were. They may be increased in various ways; first, by division, that is, by splitting up old and established plants, each piece having a few roots attached thereto. Some varieties lend themselves much better than others to this mode of increase, those of a tufted habit being by far the best. If there is a nice shady border available, this may be done as soon as the flowering season is past; but failing this, the operation had better be delayed till the heat of the summer is over. Next—and this more particularly applies to those of spreading growth—Pinks may be layered in the same way as border Carnations; but the way in which they are most extensively propagated is by means of cuttings, or pipings, as they are often termed. These are formed of the young shoots which are produced with greater or less freedom around the base of established plants. These are usually put in a border under a north wall, or in some position where they are shaded from the sun's rays without being in the drip of overhanging trees.

GARDENING OF THE WEEK.

FOR SOUTHERN GARDENS.

Plants Under Glass.

Winter-flowering Geraniums.—The plants will by now be ready for transferring into their flowering pots, if not already done. Pots of 5 inches and 6 inches will be large enough, the latter being the better of the two. Pot firmly, using a compost consisting principally of loam, with the addition of a little leaf-mould, sand and bone-meal.

Salvias.—For winter flowering these are most effective, and alike valuable for cut-flower purposes. As soon as they are ready for their final potting they may be stood out of doors. When rooting freely they must not be allowed to suffer for the want of water, or spider will surely attack the foliage. Keep the plants well syringed, and stop the growths to induce bushy and shapely plants.

The Hardy Fruit Garden.

Morello Cherries.—The growths made this season should be secured either by tying into the old wood or nailing into bare places. These must not be shortened back, as it is from these growths that next year's crop of fruit will be mainly obtained, and this variety requires plenty of growth for nailing in when the trees are regulated in the winter. Give the roots a good soaking of water, and apply a heavy mulch. If the growths are infested with aphid, give a thoroughly good syringing in the evening with an insecticide.

Protecting Fruit Trees.—As soon as the fruits begin to colour, protection must be afforded, otherwise the birds will take them before they are ripe. Wall trees should have the nets kept at a distance by sticks about a foot long with a small fork at the end.

Young Fruit Trees.—Though not carrying any fruit in most cases, these must not be neglected as regards tying and training, as a good commencement will ensure a well-trained and ultimately fruitful tree, and attention to the growths at this season before the wood gets too hard will greatly assist in keeping the tree straight. Additional strength can be diverted to the main shoots of the tree by systematically stopping the less important ones. Keep the growths clean, and mulch the surface over the roots.

The Kitchen Garden.

Cauliflowers.—As the curds mature, keep them from the light by bending down the leaves or tying with a piece of raffia. If too many become ready for immediate use, pull them up by the roots and hang them up head downwards in a cool cellar or Mushroom-house, where they will remain in good condition for a week or two. The end of this month and during next witnesses many flower shows, and in a collection of vegetables these score a goodly number of points when well shown, so that successional plants should be well watered and assisted with liquid manure. Make good any gaps in the later plantings. Hares and rabbits are especially fond of the plants. Keep well Dutch hoed and sprinkle with soot.

Celery.—Keep the crop well supplied with water during spells of drought, and the foliage dusted with soot while still damp with the morning dew. Though earthing-up is usually practised for a few early sticks, I much prefer to blanch with stiff brown paper, which in many respects is to be preferred, as the stems can be kept much cleaner and worms and slugs cannot get concealed. Commence with a strip about six inches wide, wind round, and secure with a couple of ties of raffia, and then at intervals place another tie or two. Where exhibition Celery is required it is much more easily managed in this way, and copious supplies of water are better given at the roots. I know of several cottagers who grow theirs in this manner. Later supplies are, of course, better earthed-up.

Potatoes.—Earth-up the late plantings without delay. Early sorts should be lifted when growth is completed and the haulm cleared off and burnt or disposed of, so that the ground can be occupied by another crop.

The Rock Garden.

Seed-saving.—Many of the earliest-flowering subjects will be ripening their seed, and when it

is intended to sow any particular kind, the seed pods are best cut off, placed in paper bags, and hung up in a cool, dry place, when they may be cleaned over in the winter months.

Viola gracilis.—This continues to flower profusely, and makes an excellent edging. Keep the seed-pods cut off as fast as these are formed, unless wanted for sowing.

Alpine Poppies (Papaver alpinum).—Both in the rock garden and on the front of the herbaceous borders these are now particularly attractive in their various colours, and easily raised from seed.

Remarks.—The various Thymes are now very attractive, as are also the Helianthemums with their showy flowers and the different Dianths. Keep the surface free from weeds, and lightly fork up any bare places with a small hand-fork. During dry weather water as often as necessary, and damp over night and morning.

The Flower Garden.

Ornamental Climbers.—These are invariably growing apace, and a judicious thinning of the shoots and lightly supporting and regulating them will greatly add to their appearance without destroying their character, and care should, of course, be taken not to destroy any flowering growths. Just beginning to flower is *Tropæolum speciosum*, the Flame Flower, commonly seen in the North, but not so easily managed in the South of England. When growing over some Acanthas and common Box and Yew, as it is here, the effect is fine. The growths seem to enjoy plenty of sun, while the roots like shade.

Annuals.—Keep these well supplied with moisture at the root, allow plenty of room for each plant to mature, and neatly stake any that require it. The *Eschscholtzia*, *Godetias*, *Nigellas* and *Larkspurs* are among many that are useful for cutting when grown in open positions in the front of the shrubberies. In showery weather especially, with careful treatment, the thinnings may be planted out.

Bulbs.—Tulips and other bulbs should be lifted and placed out in the sun before storing away. Named varieties should be carefully preserved in their separate sorts and labelled to prevent any confusion when planted again next season.

Summer Bedding.—The warm showers have had a beneficial effect upon the newly-planted subjects. A damping each evening in the absence of rain will do much to establish them. E. BECKETT, V.M.H.
Aldenham House Gardens, Elstree, Herts.

FOR NORTHERN GARDENS.

Fruit-Houses.

Late Grapes.—The clusters should be examined for the last time, removing those berries which have not stoned, as well as thinning the berries where they are too close.

Surface-Dressing.—Soot, if enough is applied, is valuable as a colouring agent and to keep the foliage healthy; also a good proprietary Vine manure should be applied, and shortly afterwards the borders watered. Growth on the Vines will recommence, and must be rigidly suppressed as it appears. If crops are heavy, the Vines must not be hurried, but permitted to mature the crop slowly, which results in good colouring and enables the Vines to prepare for next year's campaign. There must be no stinting of liquid, else the soil becomes too dry for healthy root-production.

Hardy Fruit Garden.

Fruit-Picking.—Much labour will be required to keep ripening Strawberries from spoiling. Much depends on the weather for quick or tardy maturing, but, as a rule, the beds should be systematically relieved of ripe fruits twice a week; in very hot weather three times. Over-ripe fruit is of less value than that scarcely quite ripe.

Summer Pruning.—Endeavour to finish this operation soon, the sooner the better. Those who have for any reason to defer this work do so at the expense of the health of the trees, which feel the loss of matured foliage more than that which is young. Continue to watch the extension of the growths on young trees, and fasten them neatly

and securely to the walls. Should aphid prove troublesome, drench the foliage with soapsuds to which a small proportion of petroleum has been added, mixing it well by pumping it with the syringe. Quassia Extract is a valuable summer wash for aphid.

The Vegetable Garden.

Shallots.—The time has arrived for harvesting this crop, which, after cleaning from dead leaves and roots, should be stored in a cold and dry shed.

French Beans.—For late picking seeds should be sown in cold frames in friable, fertile soil a foot in depth. The seeds may be planted 6 inches apart, the space to be widened once the plants are up. The sashes are not needed till cold nights in late autumn, when the plants must be well protected. Osborne's Forcing is one of the best.

Globe Artichokes.—These are now producing heads, and it is very important to cut all before they become too old, which keeps the plants in bearing. On the other hand, when left to flower and decay they cease to throw more stems. It is a good plan to have young plants for a portion of the crop, these producing later than old ones.

Herbs.—Too frequently it happens that in the rush of other work these are neglected, but it is worth while to devote some time to cutting off the stems of Sorrel and the flower-heads of Thyme and Sage. Fennel has such a beautiful flower that the blooms may be preserved for vase-filling; but the above, Mint, and any others requiring attention should certainly be seen to.

Celery.—The earliest batch will now be large enough to have a few inches of soil placed in the trenches, and that planted six weeks ago will be benefited by having an inch in depth of soil from the ridges spread over the surface of the trenches. This has a very beneficial effect, especially in dry weather. Any plants yet to be put out should be planted without further delay.

The Plant-Houses.

Malmaisons.—Some of the earliest plants will have flowered, and though it is not essential to propagate so early, a few layers may be made. The best method is to plunge the balls of the old plants into cold frames, and to put down the layers either into prepared soil or into 3-inch pots. If plants infested with eelworm have to be utilised, very short layers should be made, the parts nearest the tips of the shoots being usually free from infestation.

Begonia Gloire de Lorraine.—Those in 4-inch pots, if potted on into 6-inch or 7-inch ones, will quickly make large plants. A suitable compost is one part light rotten turf and one part leaf-soil. If the soil is heavy, employ it in equal parts with leaf-soil. A small proportion of manure may be added. In this the plants make very rapid progress. An occasional vaporising with nicotine is essential, else the mite which infests this plant very soon renders the foliage unsightly. A high, moist atmosphere suits them at this time of year.

Tuberous Begonias.—Cuttings taken now of special varieties will strike root if inserted in light soil in thumb pots, which should be stood in a cool structure and shaded from the sun. They are slow in rooting, but with ordinary attention nearly all form roots and make nice little tubers, which are valuable for flowering the second year. Plants coming into flower should have the water at the root always slightly strengthened with manure, cow or sheep manure or sulphate of ammonia being suitable.

The Flower Garden.

Gilia coronopifolia.—Seeds of this brilliantly-coloured species should be sown now or soon. The plants grow very slowly while young, and unless started early, they do not flower till late in the second year.

Hollyhocks.—The latest seedlings will now need a stake to each. It need not be very long, only sufficient to steady the spike. Old plants with several spikes are very decorative, and must be examined from time to time and the advancing spikes slung to a central stout stake. The Hollyhock rust disease appears about this time, and the whole plant should be dusted with flowers of sulphur, any leaves that are affected being removed and burned.

R. P. BROTHERSTON.
Tynningham, Prestonkirk, N.B.

THE KITCHEN GARDEN.

TURNIPS.

IN order to keep up a good and constant supply of sweet, tender, fleshy Turnips during the autumn and winter months, two or three sowings of seed should be made at intervals during the month of July, and, in the more favourable parts, the first week in August will not prove too late for the last sowing. For these later sowings I usually depend on Six Weeks and Veitch's Red Globe, both of which are most dependable varieties, and with care and attention will keep sound till late in spring. The land for this crop should be rather firm and in good heart, and have an open position, so that the plants may grow sturdy and robust. Assuming the ground is in readiness, let the drills be drawn 2 inches deep and 18 inches apart, and if the soil is dry, water the drills thoroughly some time previous to sowing the seeds. If birds are troublesome, damp the seeds with a little oil and roll well in powdered red lead. It is a good plan to put about the quantity of seeds required in a flower-saucer, then drop just enough oil to damp the whole of the seeds, scatter enough powdered red lead to just cover them, and then roll with the fingers till they have become well coated over. In this way the birds do not, as a rule, interfere to a great extent. Thin early and keep the hoe in frequent use, both to stir the soil and destroy weeds. To keep the bulbs fresh and sweet during winter is practised in various ways. I find that the best and least troublesome method is to lift the roots when they are the size of cricket balls, and bury them in trenches about three inches beneath the soil with the tops intact. In this way, with a slight covering of litter in very severe weather, the bulbs keep firm till very late in spring. Beet and Carrots are wintered in exactly the same way, and will keep fresh till those sown in spring are large enough for use. Our earliest Turnips to bulb in spring are Early White Milan and Munich; both are small-leaved, and can be grown either in frames or rather thickly on snug borders. They do not last sweet and tender for long in hot weather, but their goodness may be prolonged if lifted and laid in trenches on a cool border.

H. MARKHAM.

REPORT ON MARKET FLOWERS.

THE extensive cultivation of flowers for market is one of the developments of modern farming, of which, as yet, there has been no record, although in many parts of England its importance as a means of exploiting land which would be less profitably devoted to ordinary farm crops is well recognised. The counties in which flower-growing is most widely practised are, according to a recent report issued by the Board of Agriculture and Fisheries, Lincoln, Cambridge, Middlesex, Norfolk, Devon, Somerset, Cornwall, Cheshire, Lancashire, West Riding, Sussex, Kent, Hampshire and Surrey, but there are very few English counties from which some returns were not received, while in Wales and Scotland the industry has established itself in a few localities. Among the flowers most extensively cultivated are Asters, Chrysanthemums, Daffodils, Dahlias, Lilies of the Valley, Narcissi, Nasturtiums, Pansies, Roses, Sweet Peas, Violas, Violets and Wallflowers. The total area devoted to the

cultivation of flowers and shrubs appears to be slightly more than four thousand acres, and the gross value of the production is put at £121,000.

The great extension which has in recent years taken place in the cultivation of crops under glass has, of course, considerably increased the total output of the land. Among the crops included in one or more of the returns received, Tomatoes were the most widely grown, being included in forty-five returns from twenty-two counties. The value of the crop so returned was £43,000. Many of the returns did not state the extent of glass under which the crop was grown, but from those in which the area was stated it appeared that on twenty acres a crop of over six hundred tons was cut, being an average yield of over thirty tons, valued at £830 per acre. Next to Tomatoes, Cucumbers, Grapes and Chrysanthemums seem to be the crops most largely grown under glass, but other crops included in more than one return were Strawberries, Peaches, Lettuce, Radishes, Beans, Rhubarb and Narcissi. The returns in which the area of the glass and the value of the produce of all crops grown thereunder was given represented 155 acres with a total output of £150,000, or £968 per acre.

OBITUARY.

WILLIAM FYFE.

It is with feelings of deep and sincere regret that we announce the death of this well-known gardener,

THE LATE WILLIAM FYFE.

which occurred on June 24. For a period of nineteen years Mr. Fyfe had been head-gardener at Lockinge Park, Wantage, the beautiful Berkshire residence owned by Lady Wantage. Mr. Fyfe had been in indifferent health for the last few years; but the sad news of his death from appendicitis is sudden, for we had the fleeting pleasure of meeting him, apparently well, at the recent International Exhibition. At this exhibition his success in the large Grape class is still fresh in our memories. It was as a fruit-grower that he excelled, and his beautifully-arranged collections of early fruits, particularly at bygone Temple Shows, will long be remembered. He was also a successful competitor with vegetables; and, indeed, it may be said of him that he was a good all-round gardener. The remarkable success achieved at Lockinge in the culture of Rose Fortune's Yellow has been commented upon in earlier issues of THE GARDEN. He will always be remembered, by those who know him, as a genial Scotsman, a keen politician, and one

always willing to further the interests of those who worked under him. He was a member of the fruit and vegetable committee of the Royal Horticultural Society. The deepest sympathy is expressed with the widow in her sad bereavement.

THREE BEAUTIFUL GARDEN LILIES.

AMONG those Lilies which show colour and form in the highest degree, and also furnish a reasonable certainty of permanently establishing themselves in gardens under stated conditions and treatment, three at least are conspicuous. Of this trio the earliest to flower is the citron yellow form of the Caucasian Lily,

Lilium szovitzianum.—Though often confounded with *L. monadelphum*, it is quite distinct and vastly superior. Growing to a height of 4 feet and more, it flowers in the early day of June; the floral segments are thick, wax-like, and sharply recurving as in the Martagon Lilies, to which group it belongs; the stamens are coloured red and form an effective contrast to the citron yellow flowers; the growth of this Lily in spring is not precocious, and I have not found it adversely affected by late frosts. The flowering season of

Lilium testaceum (the Nankeen Lily) follows the previous species, and is at its best during the first fortnight of July. Generally regarded as of hybrid origin, *Lilium testaceum* is, by reason of its colour, one of the most distinct. The stems are chocolate brown, densely clothed with leaves, which gradually diminish in size as they approach the terminal heads of drooping nankeen flowers. In these the petals reflex and the anthers are coloured red. *Lilium testaceum* reaches a height of 5 feet and more when established, and though one of the earliest Lilies to appear above ground in spring, any light protecting branches will ward off frost and break cutting winds.

Lilium Henryii is a comparatively recent introduction, having been introduced from Western China twenty-two years ago. It has proved a valuable garden plant, as when established it grows to a height of 6 feet to 8 feet and bears twelve to twenty-four flowers on each stem, flowering in the open during the latter part of July and the beginning of August. The flowers are orange yellow; the colour is deepest in positions where the plants are screened from the midday sun. *Lilium Henryii* belongs to the group "Archelirion," to which section *L. auratum* and *L. speciosum* are attached. So closely does it resemble the latter in a general way that on its first appearance it was known as the yellow *speciosum*.

All of these Lilies attain perfect development in soil composed of rich fibrous loam and decayed leaf-soil, and if a mulching of well-rotted cow-manure is given every spring, their steady increase is assured. Even upon limestone soil these Lilies promise to increase in no uncertain manner. Home-grown bulbs of any of these Lilies can be procured from English trade growers, and are far superior to imported ones. Planting can be carried out during October and early in November. *L. Henryii* is a stem-rooting Lily and must be planted deeper than the others named; 3 inches to 4 inches of soil above the bulbs is a good depth, allowing 6 inches of soil for *L. Henryii*.

THOMAS SMITH.

ANSWERS TO CORRESPONDENTS.

RULES FOR CORRESPONDENTS.

QUESTIONS AND ANSWERS.—The Editor intends to make THE GARDEN helpful to all readers who desire assistance, no matter what the branch of gardening may be, and with that object will make a special feature of the "Answers to Correspondents" column. All communications should be clearly and concisely written on one side of the paper only, and addressed to the EDITOR OF THE GARDEN, 20, Tavistock Street, Covent Garden, London, W.C. The name and address of the sender are required in addition to any designation he may desire to be used in the paper. When more than one query is sent, each should be on a separate piece of paper. Plants for naming should be clearly numbered and securely packed in damp grass or moss, not cotton-wool, and flowering shoots, where possible, should be sent. It is useless to send small scraps that are not characteristic of the plant. Letters on business should be sent to the PUBLISHER.

FLOWER GARDEN.

LUPINES DROPPING BUDS (Mrs. C.).—White Lupines are particularly subject to dropping their unopened flower-buds when the soil in which they are planted becomes dry or the root becomes otherwise injured. It is always well to plant them where they are well within reach of moisture.

INJURY TO PHLOXES (L. E.).—The Phlox is attacked by the root-knot eelworm (*Heterodera radicola*). You will find little swellings on the roots, and these are teeming with eelworms. Possibly the pest was introduced with the manure. A dressing of quicklime in the autumn and of sulphate of potash now would do something to improve matters. Many different kinds of plants are subject to the attack of these pests, and no Phlox should be planted on the same soil.

LILIIUM AURATUM (F. V. H.).—We fear you will not find much virtue in the peat-moss litter as received in the bales for stable use, owing to the process of drying and preparing. Subsequently, unless it has been long laid up, turned and incorporated with the soil, it so retains more powerful salts as to become a source of danger if used too near the roots of the plants. Many Lilliums do not require peat at all, and the fact that yours have done well till this year goes to prove that peat is not essential to the species above named. If you experiment at all, our advice is to proceed slowly and use it in moderation. Gardeners generally prefer not to use it unless it is very old.

PHLOX FAILING (Phlox).—We found no insect or grub of any kind in the sample submitted, nor, indeed, any evidence suggestive of insect-life as the cause. Should wireworms exist to any great extent, these may upon occasion perforate the stem, though this pest does not usually attack these plants. The condition of the stems, so far as we could determine (they were much withered when received), was due to injury at or near their base, but we cannot say what has caused the mischief. The splitting noted in one stem is the outcome of rupture, due probably to sudden sharp frost while the stems were young and sappy. Only one of the stems, however, had so suffered, apparently, hence the difficulty of arriving at any definite answer for the whole.

PLANTS FOR FLAGSTONE PATH (D. P. S.).—The most expeditious way of furnishing the interstices between the stones would be to break up the plants of any Sedums you have, and prick out the small portions between the stones without delay. Such Sedums as *acre*, *ureum*, *Lydium*, *hispanicum* and its variety *glaucom*, *dasyphyllum*, *coriaria* and *album* are well suited to the work, and any little fragment will take root. *Campanula pusilla*, *C. p. alba*, *C. pulla* and *C. muralis* are all good, and may be similarly treated. *Thymus Scrypyllum coccineum* is a most charming plant, and any of the *Aizoon Saxifragae* would do admirably. Such Mossy Saxifragae as *densa*, *Whitavii* and *muscoidea atropurpurea* would also prove suitable, and would be best pulled to pieces and planted in August or September. Seeds of *Erinus alpinus*, *Antibactia* and other plants might be sown very thinly in position, provided the soil is good enough. Cuttings of any suitable plants, if rooted in the next few weeks, could be planted in September.

THE GREENHOUSE.

LIGHT-COLOURED DARWIN TULIPS FOR A DARK BORDER (E. F.).—Bearing in mind the limitations imposed upon us by our foreign correspondent, viz., that the Tulips should be about the same height and flower about the same time as *Clara Butt*, and also that, if possible, they should be catalogued in Krelage's list, we would advise as follows: (1) White shades, Painted Lady and Innocence (a pure white Cottage variety); (2) pink shades, The Fawn (Cottage) and Flamingo; (3) pale lilac and mauve shades, *Gandin*, *Batavier* and *Alphon* (Cottage.) It will be noted that three are classed as "May-flowering Cottage Tulips," but they are so similar in their general appearance to Darwins that they may be planted together with the happiest results.

INJURY TO CARNATION (Malmaison).—The Carnation is attacked by the grub of the Carnation-fly (*Hybomyia nigrescens*). This fly is very like a common house-fly in appearance, and about the same size. It lays its eggs either on the foliage or near the root of the Carnation, and you will find the legless maggot feeding in the stem. No better remedy than hand-picking can be used, for the fly is about so long that nothing put on the plant with the object of driving it away will be likely to do any good. The shoots affected can usually be easily detected, and should be pulled out and destroyed as soon as seen. Some growers pick out the maggots with a needle.

THE NEW FUCHSIA BENITA (J. G. K.).—We presume that your reference to Fuchsias above one's head applies to the cordon-trained examples shown at the International Exhibition, Chelsea, by Messrs. Veitch. If so, we may say that the variety *Benita* is of neat, compact growth, and therefore as widely removed from these lofty specimens as it is possible to be. Furthermore, in our own note, which was published in THE GARDEN for May 18 (before the opening of the "International"), we stated that this particular variety was shown at a meeting of the Royal Horticultural Society on April 30. It is a charming little Fuchsia, but whatever its main characteristics may be, it is not a giant in stature.

ASPIDISTRAS (S. P.).—We have never been troubled with the white worms in the soil of the Aspidistras, though, strange to say, we have of late been consulted two or three times in the matter. The pests must have been introduced either in the soil or in the water given to the plants. Lime-water would, in all probability, destroy them. You may prepare this by putting a piece of unslaked lime the size of one's fist in half a pail of water, and allow it to dissolve. After this, stir the water and allow it to stand till quite clear, when it must be poured off without disturbing the sediment. Then water the plants with this, allowing it to drain freely away. The water when clear will only hold a certain amount of lime in solution, and this will not be sufficient to injure the plants.

SEEDLING FREESIAS (E. K. T.).—Freesias, if they are potted singly, may be put into pots 3½ inches or 4 inches in diameter, but we should prefer to place five or six in 5-inch pots. They must be arranged to have all the possible space, that is, four or five disposed equidistant from each other near the edge of the pot, and one in the centre. A suitable soil may be made up of three parts of good loam, two parts of leaf-mould and one part of sand. They may then be placed in a frame or greenhouse, but should be kept rather close and shaded for a few days until they recover from the check of removal. After that they must have plenty of air and light, while a little shading during the heat of the day will be beneficial. As the pots get furnished with roots, an occasional stimulant will be of great service.

AN UNKNOWN DISEASE (Mooriland).—In your far-off clime you would appear to have a *Pelargonium* disease that we are unacquainted with, and which we hope will not find its way to this country. From what you say we think that it is caused by a fungus of some kind, and should suggest spraying the plants with some recognised fungicide. Potassium sulphide, or liver of sulphur as it is often called, is frequently used for the purpose. This is prepared by dissolving an ounce of potassium sulphide in a quart of hot water, and then making it up to two and a-half gallons with cold water. Permanganate of potash dissolved in water is also a good fungicide. This should be used of such a strength that the solution is of a pale rose colour. We are sorry that it is impossible to give any exact information, for such a trouble is new to us.

PALMS (Anxious).—There is little doubt that the cause of the ill-health of your plant of *Kentia belmoreana* is the exposure it received after the pot was broken. You could not have done better than to have repotted it at once and placed it in a warm house, keeping it frequently syringed. Shading from the sun would also be very essential. These Palms require to be well supplied with moisture at all times. Of course, when repotted and there is a mass of fresh soil around the roots, Palms need decidedly less water than when they are fully established and the roots permeate the entire ball of earth. The compost named by you is very suitable for the *Kentias*, and, in fact, for Palms in general. The amount of injury a Palm would sustain by being exposed in the manner detailed by you would, of course, to a great extent depend upon the conditions under which it had previously been grown. If it had been kept in a structure where a high temperature and a large amount of atmospheric moisture were maintained, it would, of course, suffer far more than one grown under harder conditions. We know of no book on the subject likely to suit you.

ROSE GARDEN.

ROSE FOLIAGE INJURED (W. Craig).—The foliage has been attacked by the Rose slugworm. Syringe well upon the under side of the foliage with Jeyes' Horticultural Wash or Tobacco wash, and repeat this at frequent intervals.

SOIL FOR ROSES (E. L. C. F.).—The sediment from a pond is very rich in food for Roses, and would be excellent to use in forming new Rose-beds next autumn. We would advise you to add about one part of this material to one part of good turfy loam, the top spit from a meadow; but if this is not available, then with good soil from your kitchen garden—soil that has been well enriched for a few years with manure. If you could provide a depth of 3 feet of such compost, it would enable you to grow some splendid Roses, adding, as you suggest, lime and manure. This latter should be in a well-decomposed state, that is,

from a heap that has been thrown up for twelve months, unless you can obtain good manure from a farmyard where there is very little straw in its composition.

FRUIT GARDEN.

GOOSEBERRIES FOR INSPECTION (Cromer).—The Gooseberries are not attacked by the American Gooseberry mildew or by any other disease. They appear to have been bruised, and probably have been kept too long after picking.

MULBERRIES NOT RIPENING (E. G.).—We can only account for the failure of your Mulberry fruits to ripen that the roots of the tree have penetrated a very cold or wet streak of soil. Probably if you drained the ground about the roots some good might be done. The specimen sent for examination is the Jerusalem Sage (*Phlomis fruticosa*).

FRUIT TREES AS A GARDEN SCREEN (J. M.).—Cordon trees of the fruit you mention would answer the purpose very well, we think. As we presume your fence will be rather low (less than seven feet), double cordons would succeed better than single cordons. The following varieties are good: Pear Williams' Bon Chrétien, Apple James Grieve and Plum Victoria or Old Green Gage. Yes; certainly you may plant flowers in the border, but not within a foot of the stem of the trees.

SCALE ON APPLE TREE (H. W. S.).—The Apple tree is infested by the scale insect called *Leucaniam caprea*, an insect which lives on a number of other trees as well. At this season eggs only are present, so that no spray can usefully be applied. Later, towards the end of the summer, these eggs will be hatched, and then spraying with paraffin emulsion or with a nicotine wash will be the best remedy to apply. Spraying the trees with 2lb. of caustic soda, three-quarters of a pound of common treacle and ten gallons of water about the end of February would be a useful measure to adopt.

PLUMS NOT SETTING (W. F. M. C.).—We fear it is impossible to say, without seeing the trees, why your wall trees have failed to fruit. From what you say, however, it looks as though they were not properly fertilised. Were other varieties in flower at the same time, and were insects present to carry the pollen? *Victoria* does not require foreign pollen, but many other varieties do. Your best plan, since the Pear-midge larva have made their way into the earth, will be to remove the top 2 inches or 3 inches of soil during the winter, and either burn it or bury it deeply, replacing with fresh. The use of Vaporite would be of doubtful value.

CATERPILLARS ON FRUIT TREES (B. H. A.).—The best wash to apply now for the purpose, is the following: Arsenate of soda (dry), 3oz.; acetate of lead, 6oz.; water, 10 gallons. Dissolve both together in the water and well stir, afterwards adding half a pound of treacle. The same insecticide may be obtained as a paste, called Swift's Arsenate of Lead Paste. It may be had of any sundriesman advertising with us. When ordering, state what it is wanted for. This wash destroys all biting insects, such as caterpillars, moths, &c. It should be applied in a very fine spray through a knapsack pump or syringe, taking care that every part of the foliage is wetted thoroughly. One spraying should suffice. If it does not, spray the affected parts again. One winter spraying with caustic alkali wash is sufficient if carefully and effectively applied to every part of the tree. A too frequent application of these strong washes is inimical to the health of the trees. Early in February is a good time to apply the latter.

KITCHEN GARDEN.

CABBAGES GONE WRONG (H. D.).—No fungus or insect was present, but the Cabbages looked somewhat as though they had passed their best and had begun to decay, perhaps through wet and cold.

CUCUMBERS WITH RED SPIDER (A. Skelton).—The best thing to do with your Cucumbers is to syringe them heavily every morning and evening with clear water. If persisted in, this will soon eradicate the red spider that you complain about, although it would have been better had you adopted it as a preventive. In addition to syringing the plants, also keep the pathways and all woodwork well damped down so as to create a humid atmosphere.

OLD SEAKALE ROOTS (E. A. P.).—Cut off all the flower-spikes at once. Let the plants grow as freely as possible during the summer. There will be nothing to do to them, except to keep the ground round them free from weeds. As soon as the leaves are dead (in the autumn), clear them away, taking care not to injure the top or crown of the roots in doing so. The crowns should then be covered over with sifted ashes about three inches deep. At Christmas-time, place over the roots large Seakale pots (inverted, of course), and then over and among the pots place a quantity of fermenting material, such as strawy litter from the stable, and fresh leaves in equal parts. Tread this material firmly down among the pots, covering them over from 9 inches to 1 foot deep. This material, when it ferments, will create a mild growing heat, and in five weeks' time you may look for some Seakale ready to eat. Another way of treating it is to bury the ground over (where it grows) to a depth of 12 inches with soil, leaf-mould and clean sifted ashes some time in March. The result will be that in April well-blanching, delicious Seakale will grow through this covering of soil. It should be cut off at the crown of the root as soon as the tip end of the growth appears above ground.

EDITORIAL NOTICES.

Every department of horticulture is represented in **THE GARDEN**, and the Editor invites readers to send in questions relating to matters upon which they wish expert advice.

The Editor welcomes photographs, articles and notes, but he will not be responsible for their safe return. All reasonable care, however, will be taken, and where stamps are enclosed, he will endeavour to return non-accepted contributions.

As regards photographs, if payment be desired, the Editor asks that the price required for reproduction be plainly stated. It must be distinctly understood that only the actual photographer or owner of the copyright will be treated with.

*The Editor will not be responsible for the return of artistic or literary contributions which he may not be able to use, and the receipt of a proof must not be taken as evidence that an article is accepted. Publication in **THE GARDEN** will alone be recognised as acceptance.*

Offices: 20, Tavistock Street, Covent Garden, W.C.

NOTES OF THE WEEK.

An Interesting Martagon Lily.—Lilium Martagon Cataniae is a very deep-coloured Martagon Lily, darker in shade than the variety dalmaticum, but quite a good grower, though not increasing rapidly. It is by no means showy, but it is pleasing in its own quiet way, and is generally liked by those who see it and are not entirely wedded to gay or bright colours. It does well in an ordinary border where the soil is inclined to be light.

The Kilmarnock Spotted Orchis.—The Kilmarnock variety of the Orchis maculata is a scarce and very beautiful border or bog plant which is to be found in a few Scottish gardens. It was, we understand, found a good many years ago on a moor in the Kilmarnock district, and has been cultivated in gardens since that time. It is usually very fine in the garden of Colonel Maxwell-Witham at Kirkconnell, Newabbey, and there is at present a very good group in that of Mr. James Davidson, Summerville, Dumfries, where it has been looking very fine indeed in a border with a background of Cassinia fulvida. It is a really noble Orchis, with long, densely-flowered spikes of purple blooms and handsome spotted leaves.

Statices Suworowi.—This annual species of Statice with an awkward name, which was introduced from Turkestan in 1883, is, when grown in pots, of considerable value for greenhouse decoration, as its long, strangely-disposed spikes of blossoms attract attention by reason of their beauty and uncommon appearance. In colour the flowers vary from white to pinkish mauve or lilac. They also retain their freshness for a considerable time. In order to have good examples at this season, the seed should be sown early in the year. Besides this, the different shrubby forms which used to be so much grown as large specimen plants, such as Statice profusa, S. intermedia and S. Holfordii, are all desirable in the greenhouse, the pretty blue flowers being very effective, while, what is more, if they are cut before their beauty is over they may be dried for use during the winter months.

Killing Cutworms.—That poison bran-mash is the best thing to kill cutworms is the belief of Mr. A. L. Lovett, Crop Pest Expert of the Oregon Agricultural College, Corvallis. "The cutworms pass the winter in the soil as partly grown larvæ," he says. "They are in the soil in the spring when the ground is prepared for planting. The poison mash should be sown over the ground a few days before the crop appears. If there is no green vegetation, the worms eat the mash greedily, and the field is freed of them before the plants appear. For later treatment the only way is to put a small heap of the mash around the base of the plants to be protected. To make the mash, mix sixteen pounds of coarse bran, a pound of Paris green,

half a pound of salt, a gallon of any cheap syrup, and enough water (warm) to make a heavy mash. Poultry should not, of course, have free range where the poison is."

Rose Mme. Alfred Carriere.—This charming white Rose has been flowering particularly well in many gardens this year. Although the blooms are not so full as those of some other varieties, they are exceedingly pleasing, and, as they are produced over a long season, are often available at times when other Roses are devoid of bloom. We recently saw a huge specimen in a vicarage garden in Essex, the head of which was at least 7 feet in diameter.

A Good New Pea.—A new second-early Pea that has done remarkably well with us this year is Carter's International. It is a strong-growing variety, attaining a height of nearly six feet, and produces a heavy crop of large, slightly-curved deep green pods. These contain on an average ten large Peas each, the colour of these being a beautiful verdant green. This colour is fully retained when the Peas are cooked. The flavour is first-class, and we regard International as a good Pea in every respect. It was raised by crossing Early Morn with Duke of Albany.

Roses for Autumn Flowering.—Where a good crop of Roses is desired in the autumn, the bushes ought to have some attention at the present time. As soon as the summer flowers have faded, they should be cut out, removing each one or cluster down to the first plump wood-bud. This will induce the bushes to make new wood, which will bear flowers in the autumn. A dressing of some good fertiliser, sprinkled round the bushes and hoed in, will also benefit the plants considerably. If obtainable, a 2-inch-thick mulching of short, well-decayed farmyard or stable manure will be even better than the fertiliser.

Wart Disease of Potatoes.—The Board of Agriculture and Fisheries desire to inform Potato-growers that a case of wart disease (Synchitrium endobioticum, Percival) of Potatoes has occurred in Cheshire, and to remind them that all cases of this disease must be reported to the police or other officers appointed by the local authority for the purpose. Notifications may be sent to the Board, who will forward them to the proper quarter. The Board desire also to warn Potato-growers that in view of the rainfall of the past month, the Potato disease caused by Phytophthora infestans, De Bary, may be expected before long to attack the Potato crop, and they recommend that crops should be sprayed with Bordeaux mixture at once. This disease is not required to be notified. Leaflets as to both the above-named diseases may be obtained free of all cost on application to the Secretary, Board of Agriculture and Fisheries, 4, Whitehall Place, London, S.W. Letters so addressed need not be stamped.

CORRESPONDENCE.

(The Editor is not responsible for the opinions expressed by correspondents.)

A Beautiful Herbaceous Plant.—I am sending you some blooms of *Ostrowskia magnifica*, as I think it is one of the best herbaceous plants anyone can grow. I have twelve clumps altogether about the flower garden; three of the best are carrying 344 flowers, or an average of 114 fully-matured blooms to each plant. Some of the blooms measure 7 inches to 8 inches across.—H. G. W. [The flowers sent were remarkably fine; they are bell-shaped, and pale mauve in colour. It should not be overlooked that this handsome plant is rather tender. It does best in a sandy soil in full sun. In winter it is advisable to protect the tuberous roots with dry litter.—ED.]

A Good Border Plant (*Bahia lanata*).—The recognised name of this plant is now *Eriophyllum cæspitosum*, but it is generally cultivated as *Bahia lanata*. It does not always bear a good reputation for hardiness, but there is little fear of losing it in places with a moderate climate, wet in winter being one of its principal enemies. I saw a good plant of it the other day in Mr. James Davidson's garden at Summerville, Dumfries, where it has been in a herbaceous border for a considerable number of years. There it is taller than the generally-accounted height of from 6 inches to 15 inches, being about two feet high. It is a good plant, with small, pleasing, finely-divided leaves of a greyish or silvery appearance, and many small, bright yellow flowers. It makes a good border plant, but it is even more pleasing on large rockwork, where it hangs nicely over the stones. In a border it requires staking. Though a dryish soil is recommended for *B. lanata*, it does not seem to require this if the position is well drained.—S. ARNOTT.

Bedding Roses.—In the issue for May 11 of THE GARDEN an article on bedding Roses appears, in which the variety General Macarthur is highly extolled as a bedder; in fact, the writer adds he would prefer it—at least for autumn effect—to Richmond. Where the present writer is employed, the very opposite is the case; Richmond is far the more effective Rose. The writer quoted does not mention what soil he has to deal with, and this may account for the difference. We have a rather heavy soil and on clay. I am correct in saying that Richmond, with us, produces half as many flowers again as General Macarthur, blooms earlier and much more continuously. General Macarthur will beat Richmond for substance of flower, stronger foliage, and in being less prone to mildew attacks. I would hazard the statement that no Rose grown in a bed will make growth, form buds and come out in flower so quickly as Richmond. The variety nearest approaching it in every respect, with us, is George Reimers. They are hardly discernible one from the other when seen a little distance away.—C. T., *Hightate*.

Rose Conrad F. Meyer.—Both in my garden here and in my late garden in South Hampshire this Rose has proved most disappointing, though each has a good Rose soil. Early in May it begins throwing the loveliest blooms, larger than La France and almost as refined. It keeps it up for a fortnight or three weeks, and then the leaves get black spot, and in the course of ten days it is almost as bare as in midwinter; it recovers in a measure, but never gives another flower worth looking at. I have tried it in different aspects and with different

treatment, but the result is always much the same. My present plants are loosely trained to pillars. I much regret its failure, as it is so attractive in its earliness. Perhaps your correspondent "An Essex Reader," whose note appeared in last week's issue, might have some hints to give.—ROBERT PEEL SHELDON, *Flimwell Grange, Hawkhurst, Kent*.

Exhibiting Daffodils.—With reference to the note by "A Small Exhibitor," June 29, page 326, who suggests a revised word for "faking" and disagrees with those who condemn the practice of "improving" blooms for the exhibition bench, if we tolerate these stiff collars round the neck of our exhibition flowers to support their weak, flabby perianths, then we both encourage the creation of these feeble flowers and we knowingly mislead the public and persuade ourselves that these flowers are more even and perfect than they really are, as your correspondent Mr. Watts admits (see page 315) that he also was "almost converted" by these "neat little discs." Meritorious blooms require no "faking"; faked flowers from their very weakness condemn themselves, and must therefore suffer for the want of the necessary points which the former carries. Daffodil blooms for exhibition must be shown "looking their best," but they cannot be compared to the "*débutantes*" appearing at a *Levée*." If "A Small Exhibitor" wishes to present her at Court, Mistress Daffodil must appear as she is. He might ask, in the words of Margaret Johnson, with slight variations:

"Will they laugh at your old-fashioned gown,
Daffodil?
At your simple and quaint little gown,
As you enter the (Court) of the town:
Pass you by with a sneer and a frown,
Daffodil?
Nay, tell them old fashions are best,
Daffodil.
Old friends are the dearest and best,
And the flower we would wear at our breast
(One without disc is the best),
Daffodil."

I for one would be sorry to see the day when faked blooms would be tolerated on the exhibition table or new varieties thus presented for awards.—J. E. D.

— I really must reply to my old friend Mr. Chapman. Let us see what he says on behalf of the faked flower; but, first of all, how does he know the flower I referred to was otherwise normal? Does he know which flower it was? I understood that it was the first bloom of a seedling, and therefore there could be no "otherwise" about it; and even if it had been a deformed bloom of an otherwise perfect variety, I say it is not the deformed flowers that we want to see at our shows. Oh! Mr. Chapman, how cross you must have been when you wrote that you suppose I would have "stuck up" the flower just as it was, and to tell us that you would not go to look at it! I can see the look of angry disapproval on your usually genial countenance. But really, seriously, if I did show a deformed flower, I should be the last to expect you to go out of your way to see it. Do you really mean to tell me that, if I stuck a paper collar on, it would make all the difference? It seems to me we have come down to the very root of the whole question—a flower that I would discard from a bed of seedlings, and which you would not look at, is to be faked up and to be accepted as a good and honest bloom. If this is so, heaven help the poor Daffodil.—W. A. WATTS.

— So far there seems to have been few in favour of the suggestion of Mr. W. A. Watts of discarding artificial aid in exhibiting Daffodils, perhaps because the replies have come from those only who exhibit, and find it necessary to adopt these methods, for they surely must be the losers should paper collars be decided against by the judges. May I be permitted to write from the other point of view, namely, of those who visit the shows and for whom exhibitors exhibit, I believe? Of what value to us is a flower, for instance, which is dependent on a paper collar for its beauty of form? We go to shows to enjoy the sight of the wonderful results of modern hybridisation and cultivation, and to seek further beautiful flowers for our gardens, and if not to procure them at once, to take notes in order to be able to possess at some future date those which attract us most. How much more easily and with much less subsequent disappointment could we select them from flowers (and this does not apply to Daffodils only) exhibited in their natural state without any unnatural means of support! If some exhibitors feel that they could not do without the paper collars, could not they exhibit in a class in which artificial aid is allowed? Then we, to whom flowers in that class would be of no value, could pass on to select those which, in our own gardens with good cultivation, would be equal to those seen at the shows.—A GARDENER.

***Dianthus neglectus*.**—It is perhaps rather misleading to call this very lovely plant a "Glacier Pink," for *D. neglectus* (as well as *D. alpinus*, *D. callizonus* and *D. glacialis*) shows the most studious avoidance of glaciers or glacial levels. In fact, as I believe, there is no Glacier Pink, the alpine *Dianthus* all stopping a good way short of those high places which alone can fairly entitle their inhabitants to be called "glacial." The most flagrant misnomer is in the case of *D. glacialis* itself, which frequents, with *Primula intermedia*, the upper moors of the Engadine, and, above Heibgenblut, may be found luxuriating in the gutters by the side of the highway. *D. alpinus* appears in nature as strongly attached to the limestone as *D. glacialis* to the granite; it occupies all the turf of the Styrian limestones, between some six thousand feet to seven thousand feet. Thus also, and in the same situations and at the same elevation, grows *D. neglectus*, in a comparatively small district of the Western Alps, ranging from Dauphiné and the Greuans down through the Cottians and along the Maritimes. It climbs, indeed, rather higher than the others, ascending to some eight thousand feet; for instance, on the Col de la Croix, where in the fine turf it develops a dwarf and compact alpine form of great charm. But it is always a grass plant, growing in full soil. It is a very variable species (so, indeed, are *alpinus* and *callizonus*), and should always be bought or collected in flower, as there are many forms of lanky habit with thin and starry flowers. On the other hand, I have often found plants of dense, neat growth, with blossoms round and solid and splendid, the best of these, I am told, belonging to the Cottian Alps. On Mont Cenis the prevailing form is starry, though brilliant; on the Col de Pesio in the Maritime Alps it is especially gorgeous in size and colour. Finally, though this and all the alpine Pinks thrive well and show great beauty in the moraine, it is interesting to remember that they are all invariably plants of the upper alpine turf, having affinity of taste not with the high alpine, such as *Campanula cenisia*, but with such lawn plants as *Viola calcarata* and *Viola alpina*.—REGINALD FARRER.

Rose Bennett's Seedling.—You were good enough some four or five years ago to put into your paper a photograph of a Bennett's Seedling white weeping Rose tree in the garden here. It has grown considerably since then, and this year it is a perfect picture. It measures 60 feet in circumference and is 9 feet high. It was planted fifteen years ago, quite a small tree. I enclose a photograph of it.—J. B. WESTROFF, *Holyport, near Maidenhead, Berks.*

Diplacus glutinosus.—This is not a new plant by any means, but it is becoming somewhat rare in amateurs' greenhouses. As a free-flowering plant of easy culture, amateurs who possess houses only moderately heated would find it a grand one to include in their collections. The blossoms, which are rich orange in colour, and in form like those of the *Mimulus*, look very beautiful on nicely-grown plants. It requires no artificial heat in the summer-time, and is a fine subject for dwelling-room windows. Cuttings of young wood are easily propagated in a sandy compost.—B.

Rose Marquise de Sinety.—The flowers and buds of this variety which appeared on the cover of THE GARDEN for June 22 are extremely good representations of the Rose itself, and I feel quite sure that many readers will decide to grow some plants after seeing them and reading the reference on page 316 of the same issue. Similar colours are much needed in the Rose world, and, as far as I am concerned, I must plead to a great liking for them. "P." gives the variety a good character as a heavy or clayey soil plant, and I can recommend it as a good doer in a light rooting medium, which proves it to be a fine all-round Rose.—AVON.

Brown Calceolarias.—One does not see as many brown or bronze-coloured Calceolarias in flower gardens now as formerly, say, twenty years ago. The yellow variety, or, rather, varieties, are much in evidence, too much so, I think, in many instances. They are to be seen in nearly all the beds, in the vases, and even in the window-boxes in many gardens, the general effect not being very pleasing. There is nothing wrong with yellow Calceolarias when judiciously used, the bad effect being apparent when the plants are misused, as before stated—planted too lavishly and mixed with other colours indiscriminately. The brown-flowered variety gives "tone" to a flower-bed; the blossoms are richly coloured, and, to my mind, very charming. There is nothing glaring about them, and they harmonise so well with other colours. I confess I am fond of them, and may be considered prejudiced in their favour. I would like, however, to make an appeal for their extended culture. The time will soon come when cuttings must be put in.—G. G.

FORTHCOMING EVENTS.

THE ROCK AND WATER GARDEN.

LINARIA ANTICARIA.

A PRETTY little Toadflax which does not appear to be known to everyone is *Linaria anticaria*, whose hardness is not beyond doubt, but which usually sows itself so freely as to be practically as good as a perennial. It blooms the same season as sown if this is done in spring, but self-sown seedlings do not, of course, flower until the following year. Frequently the plants survive for several years, especially if on a piece of dry, well-drained soil, and a little attention in this respect will be well repaid by the longer life of the plants. *L. anticaria* is only a few inches high, and is of rather trailing habit. The leaves are narrow and rather glaucous in hue, and the pretty flowers are most variable in colour. Some are

P. farinosa is found cultivated in quantity in this country. Indeed, it will grow in most places if given moderate shade, moisture and a climate anything from that of the Alps to temperate. This quality needs emphasis, as some folk allege difficulty in growing it. The present writer can testify, out of a long experience, that in his level herbaceous border exposed to the sometimes pitiless Scotch climate *P. farinosa* not only forms large cushioned plants, which throw up their dainty blossoms, in spite of cold and rain, but seeds itself, which is indisputable evidence that the plant has found a home. The Bird's-eye Primrose has one little marked failing. Like other Primulas, only more so, it seems to forget that it must ever be of the earth earthy. It has a tendency to work itself out of the soil. This waywardness has to be corrected by replanting from time to time.

Some varieties of *P. farinosa* deserve to be mentioned. Perhaps the first place should be given to *Scotica*, a native of Sutherland and Caithness, where it grows in moist places. This

THE BEAUTIFUL AYRSHIRE ROSE BENNETT'S SEEDLING IN A READER'S GARDEN.

white, but there are shades of yellow, purple, lilac and buff, the greater number being decorated with a yellow lip and pretty reticulations of dark colouring. The whole appearance of this Toadflax is attractive, and it makes an excellent subject for a dry rockery or for a wall garden.

Dumfries.

S. ARNOTT.

THE BIRD'S-EYE PRIMROSE.

(*PRIMULA FARINOSA.*)

This beautiful little plant, with its small and graceful silvery leaves and dainty, delicately-tinted flowers, is sometimes called the Bird's-eye Primrose. The flowers, which appear in April or earlier, range in colour from lilac to purest white, and are borne in a many-flowered umbel on a slender spike, generally an inch or so long—longer, certainly, than the leaves from which it springs. It is as if one plant were saying to the careless passer-by, "You may fail to notice the modest grace of my leaves, but I have only to hold up to you my flower to gain the reward of beauty."

is an exquisite little Primula, with densely-powdered leaves and deep rich purple flowers with a yellow eye. Unfortunately, in my experience, *Scotica* always damps off after flowering. It may be that its heart is still "in the Hielans." However, as it seeds freely and the seeds germinate well, there is no difficulty in maintaining a stock. The Primulas *algida*, *Warei* and *magellanica* are only varieties of *farinosa*, and are hardly to be recommended, as *farinosa* will produce from seed plants and flowers equal in beauty to these so-called named varieties.

Longiflora is really an enlarged form of *farinosa*, but its leaves are not mealy and the flowers are much larger and of a deeper purple colour with a white eye. By far the most robust of this lot is *frondosa*, a plant resembling *farinosa* in most ways. What it has gained in strength it has lost in beauty. The flowers are of a light lilac colour. It comes from a far country—Thrace, but seems to have forgotten all about it, for it grows with us anywhere it is planted and grows vigorously. It is, however, very temperate; it does not like too much liquid.

Morelands, Duns.

JOHN MACWATT.

THE ROCK ROSES.

THE Cistuses, or Rock Roses, consist of numerous evergreen shrubs, the greater part natives of Southern Europe. This being a comparatively mild locality, favourable positions are necessary for their successful cultivation in this country. These, however, are not difficult to find in most gardens, even in the North, where the most likely situation will be at the foot of a sunny south or west wall. Their value for certain positions in the rock garden is well shown in the illustration of a magnificent plant of *Cistus salvifolius* in the rock garden at Wisley. A specimen dotted here and there of the dwarf-growing Rock Roses is useful

CISTUS SALVIFOLIUS GROWING AMONG ROCKS IN A SURREY GARDEN.

to relieve the flat appearance of low-growing alpine plants on a sunny rockery. Positions for a group or two can usually be found on the top of a rockery with perhaps a background of trees, where ordinary low-growing alpine plants would not be suitable. Dry, sunny banks or slopes form ideal spots to mass the Cistuses, for they thrive and flower better in poor soils which are well drained than when growing in rich loamy soil.

Seeds and cuttings provide ready means of increase. August or September is a good time to insert cuttings, which will root in a cold frame or in a propagating-frame with slight bottom-heat. Seeds are best sown in spring. As Rock Roses are somewhat difficult subjects to transplant, they should be grown in pots till large enough to plant in their permanent positions. The greatest profusion of blossoms is produced during June and early July. A selection of the most useful species should include *C. corbariensis*, a white-flowered hybrid, dense-growing, about two feet high; *C. cyrius*, large white flowers with dark red spots at the base of each petal, one of the best tall-growing kinds; *C. laurifolius*, the hardiest species, has white flowers and grows 4 feet to 6 feet high; *C. ladaniferus*, the Gum Cistus, the large white flowers blotched at the base, one of the most popular species, and *C. salvifolius*, so named in reference to the Sage-like leaves, flowers white with yellow centres.

THE ROSE GARDEN.

ROSE CLIMBING MRS. W. J. GRANT.

A FEW years ago I put in a plant of this Rose in a border near the back wall of a small greenhouse. The position was a hot one, especially for a Rose, and it did not suit the variety above named. The growth was very unsatisfactory, and few flowers opened. Then I lifted the Rose and planted it near a pillar in the open garden. No sooner had the plant recovered from its removal than it was unavoidably necessary to again shift it. This

Budding, like pruning, is dealt with every season, and may well seem a little tiring to old hands; but it is of such general interest to the beginner that a few words must be given annually for the better guidance of the fresh grower.

Although this subject was touched upon in an illustrated article in THE GARDEN for June 22, page 321, a few further practical hints may also be welcome. Under no circumstances should the operation be forced—I mean, we must not meet with any difficulty in raising the bark upon the stock, nor of taking the Rose bud from the shoot of growth and the removal of the small portion of wood covering the seat of the eye or bud. To accomplish this easily the sap upon both stocks and sticks of Rose buds must be active, and more depends upon this condition than any set dates. If it cannot be done easily, we must perform disturb and injure the bark, also the glutinous sap so necessary to a quick and sound union of Rose bud and stock.

Too many amateur budders do not sufficiently realise how necessary it is that the eye or seat of the Rose bud should be in a certain condition. If too old or too young it is waste of material and labour. A little observant thought will show when this seat is in the correct stage, as it will be plainly visible and in a condition to rest firmly down upon the exposed wood of the shoot it is to be attached to. I do not propose going deeply into the methods of budding. A few illustrations, or, better still, a practical demonstration, will make the whole matter much plainer than any written words could possibly do. Another fault lies in not tying tightly enough to ensure the seat resting firmly to the wood. Cutting into the stock too deeply when making either a longitudinal or transverse cut in the bark is a frequent mistake. Just penetrating the bark is ample; any deeper only injures, and is often the primary cause of failure.

Have everything ready to hand, and avoid any risk of the sap drying up, whether upon the bud or stock. If the buds do not come away freely, cut off the bottoms of the sticks afresh and plunge in water. Many buds are almost hopelessly dried up through the neglect to cut away green leaves directly, these absorbing all the sap in a wonderfully short time, and no after-moisture from water absorption can possibly be so good as the natural sap. If the bark of the stocks clings at all, let them be watered freely a week or so before budding. The sap artificially encouraged in the stock by this means is valuable. It is, in fact, quite natural through being supplied by root action, and is altogether different to moisture obtained by soaking a severed shoot.

Always endeavour to work the Rose bud as nearly upon the roots of dwarf stocks as you can, and similarly as close to the main stem as possible when operating upon the side shoulders of hedge Briars growing in standard form. This is of great importance in avoiding suckers, and we should aim for as little of the stock growth as possible. If dwarf stocks are properly prepared and planted, as advised in a note at the planting season, it is not difficult to work the Rose bud direct upon the base of the roots, and thus none but suckers, which are sometimes formed from the roots themselves, can be produced. The plants are, to all intents and purposes, upon their own roots, none but the Rose being able to develop, and we get the full benefit of more vigorous foster-roots.

As time goes on and the stocks naturally swell from growth, the ties will need overhauling and releasing against constriction. Any failures, too,

time it was transferred to a border on the north side of a 6-foot fence. Although some shade was thus afforded the plant, it got plenty of light, and the sun's rays had some effect on it over the top of the wooden fence. The plant began to improve very soon after it was planted in this north border, and has since borne some lovely blooms, exquisite in form and colour, and worthy of a stand in an exhibition, although no special attention has been given to it. Judging from my experience of this Rose, it seems to be a variety that does best in partial shade. The variety would do best, no doubt, on the north side of a span-roofed house when planted in glass structures, but I should like to have "P.'s" and other Rose experts' views. They would be interesting and useful to others besides myself. SHAMROCK.

WORK AMONG THE ROSES.

SINCE penning my last notes we have been favoured with several very welcome showers, and the influence these have upon insect-life has once more been demonstrated. Scarcely any insects approve of wet, and the rains have had a wonderful cleansing effect. This is only one more proof of the good syringing does, and should encourage a more general use of weak insecticides at all times.

Perhaps the most important work among Roses now is budding, which should soon be commenced.

can generally be seen in three to four weeks from budding, when it is often not too late to insert a second bud. But if we take due care as regards the condition of stocks and buds, also not to muddle the operation and bruise in any way, there will be very few failures. So far as material for tying in the bud is concerned, I have no choice between raffia, bast, or worsted. In the latter case more care against possible constriction is needed because of its more enduring character, while raffia will frequently work loose or decay about the proper time.

I want to call attention to a Rose that has been particularly good this season; that is, Sarah Bernhardt. As a dark and very sweet-scented maroon-shaded Rose it is excellent, of good shape, free-flowering, and a splendid pillar or wall Rose. We very much needed a good dark bloom in this connection, and I have no fault to find with Sarah Bernhardt. Some of my early flowers have been almost as dark as Prince Camille de Rohan, and very similar in size and form. A. P.

THE FLOWER GARDEN.

BIENNIALS AND PERENNIALS FROM SEEDS.

SEASONABLE REMINDERS.

SUCCESS in gardening operations, be they large or small, depends not a little upon doing a thing at the right moment. This is as true of seed-sowing as it is of planting or transplanting,

and by the observance of such things, in conjunction with obeying the minor details or daily routine that should come between, the best results are most likely to follow. By starting now, and by sowing seeds of, say, Antirrhinums, in the open ground, one may secure a sumptuous display of these flowers in June and July of next year that will not only be a joy to himself, but the wonder—probably the envy—of his neighbours. In doing such work as this in season the amateur is also doing it at practically no cost, since the Antirrhinum or Snapdragon is, when so treated, to all intents and purposes a hardy perennial, *i.e.*, one capable of taking care of itself in the open garden. In like manner Canterbury Bells, Sweet Williams, Cornflowers, Wallflowers, Foxgloves, Myosotis, Pansies, Violas and others may be treated, and with the best possible results, because of the sturdy examples which follow intelligent treatment. In this latter phrase is naturally included the sowing of the seeds, and there is no way to compare with that of

Sowing in Drills.—By arranging these 9 inches asunder, or more if space permits, room is afforded for weeding, for stirring the soil, for thinning the seedlings, and for any other work which may be necessary. This sowing in drills one might call the systemised plan, as opposed to the haphazard method of broadcasting, which, if not of a slovenly nature, is virtually impracticable, seeing that it excludes the cultivator from the land for the time being. The position of the seed-bed is of some importance, and while sheltered as much as may be,

should be also away from the area of large overhanging trees, which are capable of much injury to the seedlings. The greatest evil, however, is the tendency to draw the seedlings early into a weak and spindly growth, from which they are unable to recover. Hence select a position apart from trees, a border having a south-west aspect being very good.

Sowing in Frames.—Frame-sown seeds have an advantage over those sown in the open, in that the former may be kept secure from birds and animals generally, may be afforded shade should occasion require it, and likewise be given protection from heavy, pelting rains. A considerable drawback to the frame, however, is the arranging of the soil-bed at the same angle as the light, the result being that the seedlings at the lower end—the point where, naturally, most moisture collects—are usually saturated, while those at the upper end suffer from the opposite extreme of dryness. Hence a nearly or quite level surface should be arrived at.

Preparation of the Soil.—The soil of the seed-bed should be well prepared by digging, and particularly so by being finely pulverised. The upper portion may be sifted to rid it of stones and other rough material, while its enrichment will depend entirely upon local conditions. It is important, however, that the soil of the seed-bed be in good heart, since no good results can accrue from a soil of a poor or impoverished nature. The addition of very old manure might, therefore, be necessary

a twofold advantage, as a broad-bottomed drill permits of a wider distribution of the seeds, in conjunction with a firming and levelling of the trench, not possible by the first-named processes. A lath, too, of half an inch thickness, or rather more, pressed its full depth into the soil is quite sufficient for a large number of seeds, whether of the biennial or perennial classes. In such circumstances a little finely-sifted soil must needs be added for a covering. When all are sown and each line or drill is duly labelled, a nice watering should be given from a fine-rosed watering-can.

Subsequent Treatment and Generalities.—Hot weather immediately following the sowing of the seeds makes much watering necessary, and the twain do not favour a good growth. By covering the seed-bed with scrim, tiffany, or thin sacking, excess of watering is avoided during the early weeks, while birds and other tormentors of the seed-bed are kept at bay. Seeds of such as Pansy, Wallflower, Viola, Sweet William and others of known quick vegetation might be kept together at one end of the plot for convenience and special treatment, while those of large-leaved kinds, as Hollyhocks and Canterbury Bells, should be given greater room both in and between the rows. This is of the utmost importance if the plants are to be permitted a free and full development while young, and once above ground, during August and September, considerable progress is made. Gaillardias, Coreopsis, Heucheras, Antirrhinums and Columbines,

AN EFFECTIVE GROUP OF HEUCHERAS. SEEDS MAY BE SOWN NOW.

in certain instances. If slugs are known to infest the soil, give a dressing of one of the soil fumigants now in vogue, working it in freely to about six inches deep.

Depth to Sow the Seeds.—With a finely-prepared surface soil it will be easy to draw quite shallow drills for sowing the seeds. These may be formed by a V-pointed hoe and a line, by drawing a 2-inch-wide lath or stick close to the line, or by slightly pressing into the soil a 2-inch-wide lath usually kept for the purpose by gardeners. This last has

which, with many other perennials, would be destined to remain in the seed-bed all the winter, would be best as companions, while for Polyanthuses and all the Primula tribe a cool nook should be looked for apart. The lovely scarlet-flowered *Gilia coronopifolia*, a tender biennial, is a plant for frame or greenhouse treatment; Auriculas are a choice or even good border strain would be best sown in pans or boxes; hardy Cyclamen, Anemones of the *A. blanda* and *A. hortensis* groups, with *Chionodoxa* and other tuberous or bulbous rooted

plants, should be treated in a frame, hand-light, or in the open ground in a position not likely to be disturbed for some months.

The following are some of the many kinds which may be sown at the present time. The lists make no pretence at completeness, however. The majority are available in many colour shades: Perennials.—Gaillardias, Coreopsis grandiflora, Hencheras in variety, Anriculas, Antirrhinums, Anemones (many kinds), Campanula pyramidalis, C. p. alba, Campanulas (various), Carnations, Hollyhocks, Cyclamen (hardy), Polyanthuses, Primulas, Columbines, Chionodoxa, Alstroemerias and Delphiniums. Biennials, &c.—Violas and Pansies, Canterbury Bells, Sweet Williams, Foxgloves, Brompton and other Stocks, Wallflowers, Myosotis (Forget-me-not), Cornflowers, Gilia coronopifolia, Iceland Poppies, Dianthus Heddewigii, Dianthus

Happily, however, for our gardens, the herbaceous Peony suffers but rarely, or to any great extent, from the causes named, though the Tree Peony planted in exposed situations often does. In the present circumstances, therefore, I am persuaded that the great heat and drought of last year, aided not a little by the prolonged drought of April and May of the present year, are primarily—probably absolutely—responsible for the failures one has in mind.

The herbaceous Peony is possessed of a voracious, almost insatiable, appetite, and if this in some degree is not satisfied, the work of which the plant would otherwise be capable is not done, or, at least, only imperfectly. It is too seldom recognised perhaps that, given the best cultural treatment, the Peony is a plant of giant stature—4 feet or more in height, and flowers, both in size and numbers, in proportion

the present year would have been unknown. Such failures, however, are among the teachings of the years, and as the seasons vary, so must our treatment of the plants we grow vary if all their good attributes are to be brought to light. Obvious object-lessons by the way are never lost to the observant gardener, who in his own way commits them to the brain, or to his diary, in order that he may cull therefrom as occasion demands; and the amateur, if he would succeed, must do likewise. An essential in the case, however, is an increase of knowledge concerning the plants. "He that questioneth much shall learn much" is a well-known axiom; and seeing that the Editor of THE GARDEN welcomes enquiries relating to all topics in gardening, there is no reason why every reader should not be well posted up. Culturally, at the moment there is nothing calculated to do the Peony so much good as copious waterings, varied with occasional doses of liquid manure, and there need be no half-heartedness in their application. Such waterings will strengthen and develop leaf and stem growth to an appreciable extent, and these in turn will give back to the presently forming crown-buds the fullest meed of the elaborated sap so obtained.

Hampton Hill. E. H. JENKINS.

SEASONABLE NOTES ON CARNATIONS.

Insect Attacks.—During all the years that I have grown Carnations they have never been attacked to anything approaching the same degree by green fly as this season. The sparrows, happily, left the growths severely alone, and their condition was perfect until the green fly came, and it has since been a hard task to keep the enemy in subjection. Half-a-dozen prepared washes have been tried on different plants, and in no case has there been a failure where the accompanying instructions were rigidly followed; but, unfortunately, not one would prevent a recurrence of the trouble, therefore repeated dressings were imperative to satisfaction. The old-fashioned Quassia, soft soap and paraffin solution cannot be beaten; but when such excellent washes can be purchased at reasonable prices

from advertisers in THE GARDEN, it is folly to trouble to make one's own.

Layering.—The propagation of Carnations is almost exclusively done by layering the shoots during the present month, and readers are urged to put the task in hand and carry it to completion as soon as possible. One would not suggest that it must be finished in July, but the desirability of it cannot be questioned. A plant that has had time to build up a splendid rooting system will undoubtedly stand through the winter better than one that is imperfectly rooted, irrespective of whether the winter is to be spent indoors in small pots or in the beds and borders of the open garden. The earlier the layers can be prepared and pegged down, the better will the opportunity for excellent rooting be; hence the advice to do the work quickly. No phase of propagation is really more simple than layering, but the fact that excellent judgment and considerable skill are needed cannot be disputed for one moment. If the incision that forms the

chinensis, and Intermediate Stock (sow preferably in pots or pans).

PÆONIES.

If one might judge by the evidences of the failure of these plants to flower—blindness so-called—that have come to hand during recent weeks, there would appear to have been something akin to an epidemic prevailing among the Pæonies in many quarters. One correspondent, in sending a large handful of buds, says "there are hundreds like them," hence the display must of necessity have been reduced to a minimum. Now, in a general way Pæony buds are only affected by severe frosts in spring, and should these occur during the nascent period—the moment when the petals are virtually in course of formation—the result is likely to be most serious. Frosts at a later date, when the footstalks of the flower are extended and the buds are thrice as large, are less to be feared, and the worst that happens is a few damaged guard or outer petals.

Too often the plants seen in gardens are little more than one-half of this height, their thin stems and meagre growth demonstrating to the specialist that only a starvation diet has been within their reach. Years ago, when exhibiting the flowers of these plants, my specimen Pæony beds had their surfaces purposely arranged below ground-level, in order that watering to saturation point could be more easily and effectively done. The flowers I have seen this year of most double sorts—I make exception of the magnificent single Japanese grown by exhibitors—have been but little more than one-half their normal size, and the fact speaks for itself—the specialist succeeding by reason of his knowledge, by appreciation of the requirements of the subject, and by prompt application of the same. Doubtless, had the moisture-loving requirements of these plants been known and met in April and May last, when farmers and gardeners alike were suffering from an almost unprecedented spring drought, the many failures of

essential tongue is made too high up, callusing will not proceed at all satisfactorily; while if it is made too low down where the stem is more or less woody, the result will be a failure in a large proportion of, if not in all, instances. The tissues at the point of cutting should be sound and neither hard nor soft. The appliances requisite are easy of provision, since they consist of nothing beyond a knife, which must be as sharp as, or sharper than, a razor, and a supply of pins or pegs. Carnation-pins have been on the market for years (Sydenham offers one which is excellent), and the price is reasonable, or ordinary hairpins can be utilised with success; while if a supply of pegs made from the dried stems of the Bracken Fern are at command, nothing better could be desired. Given these things and a steady hand, success is bound to follow. Round each plant that is to be increased a mound of fresh soil ought to be built. A mixture of equal parts of fibrous loam and sweet, flaky leaf-mould, with a sufficient admixture of sand to keep it sweet and open, cannot be beaten for the purpose. It must be made moderately firm before starting, and then and afterwards should be maintained pleasantly moist. On varieties which make "grass" freely all weak shoots may be discarded, but in others that are not so prolific all must be retained, or there may be a shortage of stock. The stem is grasped firmly in the left hand and raised slightly. Then remove a few of the lowest leaves, and with the sharp knife make a cut from beneath running upwards through a joint for approximately 1 inch, and the necessary tongue with a clean wound will be formed. To insert this, the tip of the shoot is lifted at about right angles to its base to open the incision widely, and in that position it is secured, pegged down to the soil of the mound; covering with a little soil completes the operation. A light soil containing sand and sifted leaf-mould is preferred. It is the custom of some cultivators to put a small stone or a piece of stick in the incision to prevent closing, but when reasonable care is exercised in pegging down this is neither necessary nor desirable. The details in regard to every shoot are identical, and no one need fear that the result will be a failure if the simple instructions given are followed.

F. R.

THE TREE FLAX.

(LINUM ARBOREUM.)

This is a free-flowering dwarf shrub for a warm, sunny border and the rock garden. It requires a light, well-drained soil, for which reason, when preparing the ground previous to planting in some gardens, the plants are more likely to succeed if a quantity of old mortar rubble be worked in. In open and rather exposed positions the Tree Flax, being a little tender, is liable to damage in winter.

WISTARIA MULTIJUGA IN A BERKSHIRE GARDEN.

The plants in such positions may be afforded protection with a few Yew or Spruce branches during severe weather. Cuttings made of the young shoots during July and August root fairly easily in a slightly heated propagating-frame or gentle hot-bed. The flowering season is May and June. The flowers are yellow and produced in great profusion. Even on a poor stony soil it is quite a success. *Linum arboreum* a native of Crete, was introduced in 1788 and grows 9 inches to 1 foot in height.

TREES AND SHRUBS.

A BEAUTIFUL WISTARIA.

SEND you a photograph of the beautiful *Wistaria multijuga*, growing here in the garden of Captain F. G. Coleridge, who planted it about forty years ago at the base of a Spruce Fir, which it has taken sole possession of, there being only one branch of live wood left in the tree. Of *Wistarias* I think this to be the most beautiful. When once it starts to bloom, every small shoot produces from three to six racemes of delightful sweet-scented flowers, many of these racemes exceeding three feet in length, with as many as 160 individual flowers, and often more; the longest raceme I measured this year was 38½ inches. Where the plant can be grown in this way a most charming and effective display is produced. Last year, owing, no doubt, to the very hot season, a large number of seedpods were produced, some containing one seed and some two seeds, many of which ripened, and from which we have raised several plants. Although seed-pods are generally produced every year, it is very seldom that they ripen, as they are usually destroyed by early frost.

W. H. SCOTT.

Twyford, Berks.

BERBERIS CANDIDULA.

This dwarf-growing Barberry may occasionally be met with under the name of *B. wallichiana* var. *pallida*, though it is a rare plant and one which has only been grown during the last few years. It forms a low-growing shrub of dense habit, with stiff branches clothed with ovate evergreen leaves, the largest of which are rather less than an inch in length. Several are borne together from every bud, and at the base of each leaf cluster three strong spines are produced, each one being quite a third of an inch long. The leaves are dark green, glossy above and silvery beneath. The apex is terminated with a short spine. The yellow flowers are usually borne singly from the leaf-axils. They are large for Barberry flowers, and showy. It is a plant which might well be planted on a rock garden, or it is suitable for planting in a bed on the margin of a lawn where a shrub

9 inches to 1 foot high is required. It may be raised from seeds or from cuttings taken late in the summer. *B. candidula* is a native of Bhotan, but the same plant appears to have been received from China.

THE JAPANESE LILAC.

(*SYRINGA JAPONICA*.)

This is a very distinct and handsome shrub, native of Japan. The average height of a mature bush is from 7 feet to 10 feet, the spread of the bush being about the same as the height. The specimen shown on page 354 is twenty-five years old. The panicles, which average 8 inches to 9 inches in length, are so densely flowered as to appear almost like plumes. The colour is creamy white, fragrant, but not so pleasing as the common Lilac. The season of flowering is from mid-June onwards to mid-July, thus being a particularly valuable shrub, for by this date

stature and the stage of blossom development, but all alike are in perfect health, and full of promise of the hountiful seed crop that is so much desired not only by the proprietors of the business, but also by their most capable and experienced manager, Mr. Andrew Ireland.

To examine each plant in an area of ten acres is no light task, and I am not going to pretend that I did it, but I was forced by Mr. Cuthbertson, the principal of Messrs. Dobbie's, and Mr. Ireland to do my duty to a reasonable degree, so that it is safe to assert that I saw anything from five to eight acres in detail. I sought diligently for traces of "streak," because I felt that if it was in evidence where an acknowledged expert was in control, some of my readers would feel an element of satisfaction. I failed to find it, and Mr. Ireland was on the contemptuous side when I spoke of it. His idea appears to be that when plants are rationally grown, no "streak" or other trouble will arise,

LINUM ARBOREUM, A DWARF SHRUBBY PLANT FOR THE ROCK GARDEN OR SUNNY BORDER. (See page 355.)

a goodly proportion of the beautiful trees and shrubs of our gardens are past.

NURSERY NOTES.

SWEET PEAS AT MARK'S TEY.

THESE are many beautiful displays in the fields and gardens of all the counties of England at the present time, but after visiting Messrs. Dobbie and Co.'s seed farms at Mark's Tey and seeing the ten acres of Sweet Peas, almost all in full glory, it does not seem that there possibly could be any sight more delightful. Hundreds of thousands of magnificent plants are accommodated in thousands of yards of land, and among them may be seen those fast-setting seeds and others that have not yet reached their zenith of prolific flowering. There are plants from seeds sown out of doors in the autumn, others from seeds sown in cold frames at the same time, and still others from seeds sown in the spring, and they differ materially in

and I am firmly of the same opinion. The Sweet Peas at Mark's Tey are magnificently grown, but they are in no sense overfed, nor do they have anything beyond natural manures, and no trace of disease of any kind could be seen in the place.

Naturally enough, the principal part of the space is allocated to the choicest varieties grown expressly for the production of seed, but there are many rows devoted to novelties of the firm's own raising and not yet in commerce, as well as to introductions from other seed houses at home and abroad. The whole of these varied considerably in merit, and probably the majority of them will never be seen again; but the trueness of the British strains was far in advance of that of the imported seeds. Several of Mr. Cuthbertson's own crosses demonstrated the careful manner of working, since all the seedlings of the first generation were identical, and Mr. Ireland had sown the seeds in the precise order in which they formed in the pods.

The Editor says that I must cut my notes short, and editors are stricter martinetts than any soldier

who has yet been born. When the rule to cut down applies to other scribes I do not worry, but when I am forced to observe it myself I think it wrong, and in the present instance I am sure that all Sweet Pea readers of THE GARDEN will agree with me. I wanted to mention half-a-hundred meritorious varieties, but space forbids. The Marquis, true, is splendid, and Stirling Stent with a little more vigour would take some beating as a garden Sweet Pea. The two ladies—Mrs. Cuthbertson and Mrs. Andrew Ireland—are absolutely indispensable in the garden, precisely as they are in their respective homes. Sunproof, Crimson and Dobbie's Scarlet lend that richness which is so desirable, while Lavender George Herbert and Mauve Queen afford the opportunity for choosing the one that suits the purse the better. Brunette all will grow, because it is perfectly distinct, and none will fail to admire Duplex, Mrs. Hugh Dickson, Edrom Beauty, Lady Miller, Elfrida Pearson, Thomas Stevenson, Dobbie's Cream, John Ingman, Nora Unwin and Etta Dyke. I could easily mention others just as desirable in their way, but I must obey the order to stop. HORACE I WRIGHT.

THE FRUIT GARDEN.

WORK AMONG THE STRAWBERRIES.

AS soon as the plants have been cleared of their fruits, no time should be wasted in getting all the old, useless leaves, and runners if not required for stock, removed, so that the new growth and crowns for the production of a good crop of fruit next season may have ample time to develop. If the plants are in the least infested with red spider or mildew, give them a thorough dressing with Abol or some other safe insecticide, after which slightly loosen the surface between the rows and follow with a good mulching of thoroughly-decayed manure. This method I have now practised for many years, and am well satisfied with the results, especially where the soil is light and porous. Deep, rich soil of a somewhat heavy texture should be sparingly manured, otherwise the plants may grow too much foliage and prove less fruitful.

The Best Varieties.—Our first variety to ripen in the open this year was Royal Sovereign. We gathered our first dish about June 1 from young plants layered last July, and from two year old plants about nine days later. We have for many years depended almost entirely on this variety, both for pot culture and early supplies outside, and it is, I consider, for those purposes the very best to grow. Leader, with me, although a heavy cropper, does not do so well as several others, and the fruits are too soft and coarse on our light land. President and Sir Joseph Paxton succeed very well, and Laxton's Latest, Reward, Givon's Late Prolific and Waterloo serve us well late in most seasons.

Forced Plants.—Those who intend to plant out old plants that have been forced, with the hope of securing a good crop next year, should get them out without delay into good, deeply-cultivated land. Fully 2 feet apart between the rows must be allowed, and the soil about the roots should be made firm. If the land is already prepared, all that will now be necessary is to hoe and rake it over, stretch out the line, and plant firmly. The roots should be thoroughly moistened before turning them out of the pots.

H. MARKHAM.

Wrotham Park Gardens, Barnet.

GARDENING FOR BEGINNERS.

THE SUMMER PRUNING OF FRUIT TREES.

A GENERATION ago the summer pruning of hardy fruit trees was not carried out so extensively as it is at the present time. Winter pruning was then mainly depended upon, but cultivators now know the value of summer pruning.

It does not entirely obviate the necessity for winter pruning, but it lessens the work then and has other essential advantages. For instance, in our country we sometimes fail to get a very sunny summer; and the young wood does not mature. The timely removal of surplus growths admits light and air to the basal buds and leaves retained, and the fruit growing on the trees gets much benefit, too, the crop being heavier than when summer pruning is not done. A healthy fruit tree will make a great deal of young wood during the summer months. This is natural, and in due course the tree will become fairly fruitful, even if it does not receive any pruning at all; but the specimen would grow into a large one, and, besides being of bad shape, it would probably be quite inconvenient to have it in a small garden. In a restricted area few untrained, unpruned trees could be grown. The centre would be choked with useless wood, and the fruits matured would be on the outside branches only. In many of our old orchards such trees are to be seen in these days; but we wish to advance in the art of fruit culture, and in doing so summer pruning of the young wood is now carried out, with marked success.

By summer pruning we restrict the size of the tree and divert the nourishment of the specimen to the buds, main leaves and fruit. Judiciously done, this pruning not only prevents any waste of the strength of the tree, but helps to prepare it to produce and mature a good crop of fruit the following year.

1.—YOUNG FRUIT-BEARING SHOOTS THAT SHOULD BE PRUNED NOW.

The Illustrations Explained.—The principle of summer pruning is the same whether applied to young extended branches or to those growing on old spurs. I will refer to the former first. A shows a young branch with side shoots. During the

latter part of July and the early days of August the side shoots (B B B) must be cut back as denoted by the cross lines on each one. Three or four main leaves and buds must be left on the basal portion of the branch. In a very short time strong trees will produce lateral shoots, as shown by the dotted lines, C C C. When these small laterals are about one inch long they must be pinched out, as shown at D D D. The basal buds, denoted by E, will not burst into growth, but they will become very plump, and this is just what the cultivator wants. Probably a few sublaterals will grow again at D D D; if so, they must be pinched out when large enough to handle. In winter the shortened shoot is pruned to the basal buds on it. The leading branch (F) must not be shortened.

The second illustration shows how to deal with the young shoots growing on an old spur. A, spur and thick branch; B B, two strong young shoots, which must be cut back at the dark cross lines; C, a weaker shoot, which should be cut back almost to the spur itself to prevent overcrowding. Now, any buds left on the short stump of this shoot will grow again at once, and they must be pinched out; their growing does not matter, as the buds on the old spur, denoted by the arrows D D, will swell up well and produce flowers and fruits next year. Beginners should attend to the summer pruning of their fruit trees, particularly Apples and Pears, without much delay. By carrying out this work thoughtfully a good deal of hard pruning in the winter may be saved, with advantage to the trees. By the removal of surplus growths now, light and air will be admitted into the trees, with beneficent results. The winter pruning of the other shoots must be done in the usual way; then the old spurs will become very fruitful.

G. G.

2.—THE SUMMER PRUNING OF YOUNG SHOOTS GROWING ON AN OLD SPUR.

GARDENING OF THE WEEK.

FOR SOUTHERN GARDENS.

The Flower Garden.

Border Chrysanthemums.—Keep the soil well aerated between the plants and well water them at the roots. During showery weather give a dusting of soot to the foliage and the surface soil, and a little artificial fertiliser hoed into the surface will prove helpful. Staking and tying must be proceeded with, and if the points of the growths become infested with aphid, either dust the affected parts with Tobacco powder or syringe with an insecticide. A damping of the foliage on warm, dry evenings will greatly assist growth.

Anchusas.—The varieties of this hardy herbaceous plant have been creating a brilliant display. It is one of the finest plants for the herbaceous borders and seems to stand drought, a most important point, especially in gardens where the soil is light and porous. Young plants that were raised from cuttings and are well established may be planted out, and will make fine plants for flowering next season.

The Kitchen Garden.

Spring Cabbage.—Between this date and the end of the month make a first sowing of good varieties for spring use. Select a border or piece of ground that has had no manure recently applied, and prepare a fine tilth. Sow the seed thinly and evenly broadcast and rake in. Stretch a net over the seed-bed, or probably birds will be a nuisance. If the prevailing weather is dry, water with a roset can in the evening.

Coleworts.—Make a sowing for late autumn and early winter supplies in the open ground as advised for the above, bearing in mind not to let it follow any of the Brassica family.

Carrots.—Keep the main crop of Carrots of the intermediate kinds intended for lifting for winter supplies well hoed. If the crop appears too thick, the young roots, if carefully pulled, will be useful for culinary purposes. During spells of drought, water should be liberally given if possible, and the crop mulched. Make another sowing of a quick-maturing variety for use later on.

Parsley.—Make a small sowing in the open ground in drills for providing plants for winter use.

Vegetable Marrows.—Keep the plants well supplied with water, and a good soaking at intervals with liquid manure-water to plants that are growing and fruiting freely will be of great advantage. The growths should be regulated and stopped, and the fruits as soon as large enough should be cut, as if the stalks are placed in shallow water they will keep young and fresh for a considerable length of time.

Plants Under Glass.

Malmaison Carnations.—The time has now arrived for propagating these old-time favourite flowers, which is carried out by layering. The best method is to devote a light or two of a cold frame, containing some fairly suitable soil of a sandy nature, for the purpose. Knock the old plants out of their pots, take out a little trench in which to lay the old balls of soil, and spread out the growths evenly for layering, when with a little careful manipulation the whole surface of the frame can be covered with growths. Use a sharp knife, and cut through a joint on the under side and towards the top of the growth. Just cover the growth where the incision is made with some of the fine soil and peg down. Keep close and shaded for a week or so, and damp over with the syringe; then gradually increase the amount of ventilation until the lights may be removed entirely.

Tuberous Begonias.—These are making a grand show in the houses just at present. Remove faded flowers to keep the plants neat in appearance, and support the flowers with neat sticks. See that the plants do not suffer for the want of water, and give them assistance once or twice a week with liquid manure-water.

Fruits Under Glass.

Peaches and Nectarines.—To retard their ripening, if it is convenient to do so, the trees may be shaded by whitewashing the glass or placing mats or other material over them during the daytime, though it can scarcely be expected that the flavour will be as good.

Strawberries.—When the newly-layered plants have rooted through to the sides of the pots, they should be severed from the parent plants and allowed to remain for a few days on the beds, when they can be removed to the nearest open site to where they will be potted. This should be carried out before the young plants become pot-bound. Use clean, well-drained 6-inch pots. Put a layer of rough turfy material over the crocks. Use a compost consisting mainly of fibrous loam, with the addition of one-third flaky leaf-mould or thereabouts, according to the nature of the loam, with a sprinkling of soot and wood-ashes and a liberal dash of silver or road sand. Make sure before potting that the ball of soil is well moistened through. Pot firmly, and leave quite an inch margin for watering. Give a good soaking in and stand on a firm bottom, as it is absolutely necessary to keep the plants free from worms.

The Hardy Fruit Garden.

Strawberries.—If it is intended to make new plantations—and it is advisable in gardens of fair dimensions to lay one down each year—a supply of plants should be layered into small pots as recommended for forcing, and, as soon as the ground is ready, the plants can be put out and will become well established before winter. It is a capital practice to plant out in threes triangularly, allowing plenty of space between the clumps and rows.

Summer Pruning.—If not done too early, it is an excellent plan to shorten back the current season's growth on wall fruits, such as Apples and Pears, to within five or six buds of the base, as not only does this make the trees more attractive, but does much to lessen aphid, renders the trees less susceptible to further attacks of blight, and exposes the fruits to the sun and air, as well as concentrating more energy into next year's fruit-buds. If done too early, however, it encourages lateral growth, which must, of course, have a weakening effect.

Watering.—Every available opportunity should be secured now to apply water and stimulants to swelling crops of fruit. Even where these are minus, the trees will greatly benefit, and should not be neglected. E. BECKETT, V.M.H.

Aldenham House Gardens, Elstree, Herts.

FOR NORTHERN GARDENS.

The Flower Garden.

Roses.—The season is now on, and much labour will be necessary in removing decaying flowers, which, if time permits, should be done systematically daily.

Delphiniums.—As the flowers give place to seed-vessels on the spikes, remove these at once, which will be a means to keep the foliage of the plants green and slightly for a long time; seeding, on the other hand, soon makes it rusty and an eyesore.

Pæonies.—As these go out of flower, very large plants, which are apt to throw few blooms, may be lifted, the roots soaked in water as a means of freeing them from soil, the plants thereafter divided and immediately replanted, and the stems and foliage supported on stakes. Apply water till the plants become established.

Carnations.—Proceed with layering shoots of border varieties, selecting the best for the purpose. It is quite a usual thing to find the workman, when fresh material is used for rooting into, place it not where the roots will be produced, but above the part into which the tongue of the layer is pegged. Some varieties are very apt to break away from the main stem when putting them down. This is easily prevented by twisting round the shoot to be layered, when, unless the operator is exceedingly clumsy, there will be none thus treated break off.

The Grass.—Now that the flower garden is again becoming bright with flowers, extra care should be taken that grass along the sides of walls, at the base of pedestals and beneath specimen shrubs is not allowed to stand untrimmed and longer than the grass on the lawns. Walk and border edgings are equally unsightly, and should never be allowed to grow much, but be clipped at short intervals.

The Shrubbery.

Prunings.—Common Laurels are usually very ragged and unkempt at this time of year, and if time permits or the weather is unsuitable for other operations, they may have the stronger shoots

cut back, leaving all the short ones, so that no appearance of their having been pruned may be evidenced. Nothing excels a knife for this purpose, though there are many ingenious instruments to be had by those who dislike an ordinary knife.

Weigelas.—Now that these have done flowering, the shoots may be shortened to allow the growths for next year to grow freely, and be well exposed so as to ripen thoroughly. The many beautiful species and varieties of Weigela seem to be hardly known, yet there is nearly every shade of colour from cream to darkest crimson with white, and with foliage variegated in white and yellow.

Clematises.—The late-flowering varieties will need constant attention to secure the fast-growing shoots and to keep them from getting irretrievably entangled. The pretty little *C. Flammula* is best trained so that its shoots droop, and these will merely need to be occasionally directed so that they do not grow into bunches.

The Hardy Fruit Garden.

Red Currants.—The shoots of these may be cut back previous to netting them.

Raspberries.—Any superfluous growths should be removed previous to putting on nets, and very strong shoots at the same time slung to the wires or other supports to keep them from sagging.

Apples.—Though as a crop Apples are light, there are always varieties which set more fruits than is good for the trees to mature. The thinning of such may now be proceeded with, leaving soft, early varieties, such as Early Julian, Lord Grosvenor and Codlins generally, till the fruits are large enough for culinary purposes, when thinning may be proceeded with by degrees.

Loganberries.—If trained on rough trellises, lay in as many shoots of the current year as will replace those in bearing. It is not always the most robust shoots of this fruit that give the largest crop, therefore extra strong ones may be cut out and those of medium strength only retained. If trained to stakes the shoots must be slung loosely to them in the meantime, and side growths from the fruiting canes shortened considerably.

The Vegetable Garden.

Cabbage.—This is the most suitable time for sowing for the early spring and main early summer crop. It is preferable to sow the seeds broadcast and thin rather than in drills. Those who are inexperienced should coat the seeds with dry whitening, which enables one to gauge exactly the closeness of the seeds.

Broccoli.—These and other winter crops of a like nature will be benefited by having some earth drawn to the plants on each side and, if the soil is at all hard, somewhat loosened on the surface. Cauliflowers may require water at the root and a surface-dressing of a stimulating manure, but not Broccoli nor Brussels Sprouts, at least in the meantime.

Spinach.—A larger sowing than usual may be sown now or shortly. If the seeds are sufficiently thin in the rows, the plants will stand a long time once the cooler nights begin in August. If sown after Potatoes, the surface of the soil will merely need to be well broken up with a fork and the seeds sown forthwith. Spinach does best in not too firm a soil.

The Plant-Houses.

Auriculas.—This is a suitable time to repot all kinds. Old plants should have the soil shaken from the roots, and these be dipped in an insecticide should the white root aphid be present. The decayed part of the rootstock removed and the plants repotted in pots of the same size. Young plants in small pots need only be shifted into others of a larger size.

Humeas.—All seedlings as soon as they are large enough to handle should be transferred from the seed receptacles to cutting-boxes or 6-inch pots. They need not be more than 1 inch apart. The young plants progress much better when transplanted as thus advised than if left in the seed-pots till they become larger.

Freesias.—The earliest batch may now or soon be potted. They succeed very well in 5-inch pots, twenty or so in each, and if too contracted for all the corns to be placed on a level, a portion may be placed slightly deeper. Stand the furnished pots in a cold frame, but allow them to be exposed to all kinds of weather in the meantime.

R. P. BROTHERSTON.

Tynningham, Prestonkirk, N.B.

NEW AND RARE PLANTS.

FIRST-CLASS CERTIFICATES.

Polypodium mandaianum.—In brief, this lovely and handsome Fern may be described as a glorified *P. aureum*, having fronds 4 feet to 6 feet in length, proportionately broad, and of a deep glaucous green, whose gracefully-arching, deeply-laciniated pinnæ are almost suggestive of a plumose character. This magnificent novelty was in splendid form at the recent International Exhibition, when, as now, it was exhibited by Mr. W. A. Manda, South Orange, New York, U.S.A. It is a noble Fern and a great acquisition.

Lilium warleyense.—A gloriously beautiful and new Lily, with rich scarlet-coloured flowers, from China. These are in great numbers on the plant, and if quite representative of the new-comer, every hardy plant gardener will require it. The leaves are narrow, linear and long, not unlike those of *L. myriophyllum*, the drooping petioles suggesting those of *L. suchuenense*. A remarkable plant of great merit. From Miss Willmott, Warley Place, Essex.

Lastrea patens Mayii.—A hybrid raised between *L. patens* and *L. lepida*, having the pale green-coloured fronds of the first. The fronds are grooved, much dissected, and of considerable length, making up a highly ornamental plant. From Messrs. H. B. May and Sons, Edmonton.

Miltonia hycana Le Conquerant.—Pale rose sepals and petals, and an almost white lip with a crimson patch in the centre. Shown by M. Jules Hye de Crom.

Cattleya Artemis.—This is a fine hybrid derived from the intercrossing of *C. Iris* and *C. gaskelliana*. The sepals and petals are a light mauve, which are slightly reflexed, but the open and broad lip is a purplish magenta, with a large band of yellow in the throat. Exhibited by Lieutenant-Colonel Sir G. Holford.

Cattleya dupreana Schröder's variety.—A superb *Cattleya* having well-formed flowers, the sepals and petals being a pleasing shade of rose, while the gorgeous lip is purplish crimson. From Baron Bruno Schröder, Egham.

AWARDS OF MERIT.

Carnation Jean Douglas.—A superb scarlet of dazzling colour, whose shapely and large petals will doubtless render it a splendid exhibition variety. The flowers are supported on stout, erect stems.

Carnation John Ridd.—Yellow-ground fancy, suffused and marked with rosy red. It is regarded as one of the best fancy sorts in existence. Both came from Mr. James Douglas, Great Bookham, Surrey.

Clematis Lady Betty Balfour.—A very showy variety, whose flowers are of purplish hue. From Messrs. George Jackman and Sons, Woking.

Astilbe Avalanche.—The fine pyramids of blossom are nearly pure white; under stress of forcing they would doubtless be quite so. Shown by M. G. van Waveren, Holland.

Nephrolepis exaltata Rochfordii.—An exceptionally dwarf variety of this variable species, with plumose fronds of an almost moss-like density. In plumose varieties it would appear to represent about the last word. Exhibited by Messrs. T. Rochford and Sons, Limited, Broxbourne, Herts.

Begonia Mrs. Robert Morton.—A splendid variety of the tuberous-rooted section, of a rich,

clear golden yellow colour. The flowers are of great size and perfect form.

Begonia Florence Nightingale.—Another superb novelty, with flowers of the purest white. Both were exhibited by Messrs. Blackmore and Langdon, Bath.

Rose Ethel.—A rambler or climbing variety, with a great wealth of single, clear pink-coloured flowers. From Mr. Charles Turner, Royal Nurseries, Slough.

Rose Mrs. Charles S. Hunting.—A Hybrid Tea variety, in which pink and cream colour are in delightful harmony. Exhibited by Messrs. Hugh Dickson, Limited, Royal Nurseries, Belfast.

Brasso-Cattleya Marion.—The parentage of this pretty Orchid is unknown, but the flowers are of good shape. The colour is a light heliotrope, the lip being slightly fringed and deep mauve, with a darker streak down the centre. Shown by Messrs. J. Veitch and Sons, Limited, Chelsea.

Cattleya thurgoodiana Apollo.—Sepals and petals magenta, and a rich purplish crimson lip, which has a blotch of yellow on either side similar to the well-known *Cattleya gigas*. From Messrs. Stuart Low and Co., Enfield.

Lælio-Cattleya rubens The Kaiser.—A pleasing form of this popular hybrid, being richer in colour than the type. Exhibited by E. H. Davidson, Esq., Twyford.

Odontoglossum percultum King George V.—The flowers are large, and have a whitish ground blotched and marked with bluish purple. From F. M. Ogilvie, Esq., The Shrubbery, Oxford.

The foregoing were shown before the Royal Horticultural Society at the Holland Park Show.

ANSWERS
TO CORRESPONDENTS.

RULES FOR CORRESPONDENTS.

QUESTIONS AND ANSWERS.—The Editor intends to make THE GARDEN helpful to all readers who desire assistance, no matter what the branch of gardening may be, and with that object will make a special feature of the "Answers to Correspondents" columns. All communications should be clearly and concisely written on one side of the paper only, and addressed to the EDITOR OF THE GARDEN, 20, Tavistock Street, Covent Garden, London, W.C. The name and address of the sender are required in addition to any designation he may desire to be used in the paper. When more than one query is sent, each should be on a separate piece of paper. Plants for naming should be clearly numbered and securely packed in damp grass or moss, not cotton-wool, and flowering shoots, where possible, should be sent. It is useless to send small scraps that are not characteristic of the plant. Letters on business should be sent to the PUBLISHER.

FLOWER GARDEN.

WOUNDED POPPIES (H. M.).—An insect, apparently a minute two-winged fly, has laid her eggs in the stem of the Poppy. You will find the larvæ which have hatched from them in the wounded parts. The life-history of this insect is unknown, and it does not appear to be common. Probably the enclosure of any specially-desired buds with muslin would save them. The attacked buds should be burned.

VIOLETS WITH HIDDEN FLOWERS (C. T.).—The ordinary flowers of the Sweet Violet very rarely produce seed. The seed is produced in small flowers, like those you send, and known as cleistogamous flowers, from the fact that they never open. They are somewhat dependent upon the conditions around the plant for their formation, and possibly, if the Violet were transplanted to other quarters, it would produce flowers, though it may possibly be that the plant in question has lost the faculty of ordinary flower production altogether. The cleistogamous flowers are borne after the ordinary ones are all done.

INJURY TO PHLOXES (H. A.).—The Phloxes are badly attacked by the stem eelworm. The rolling of the leaves and the malformation of the stem have been brought about by these pests, and they are likely, unfortunately, to be carried on to other years. The tissues are filled with eggs,

and so all diseased parts should be removed as soon as possible and burned, not consigned to the rubbish-heap. Propagation should only be done from healthy plants; and as the pest exists in the soil and gains entrance into the plants from the soil, the latter should have a dressing of sulphate of potash at the rate of at least 1 lb. to each 20 square yards, and double that quantity may be used.

THE GREENHOUSE.

PITCHER PLANTS (Ladona).—Whether you take the plants out altogether from their Teak baskets will depend upon the condition the roots are in. If they are in good condition it would perhaps be as well to remove as much of the old soil as possible without unduly disturbing the roots, and replace it by some fresh compost made up of fibrous peat, sphagnum moss, silver sand and nodules of charcoal. Whether the plants need re-basking can only be known by personal inspection, but if in your opinion this had better be done, the same compost as above recommended will be suitable. If you have a propagating-case in the stove with bottom-heat, the tops of the plants that are cut off may be put in as cuttings.

GLOXINIAS (X. Y.).—There were a few thrips on the leaves sent, but the major portion of the injury seemed to be caused by that destructive little mite usually referred to as the *Begonia mite*, from its having been first noticed on these plants. Its ravages, however, are greatly on the increase, for we have had numerous examples of injury done by it on different plants during the present season. Probably the hot, dry summer of last year had something to do with this, for heat and drought are very favourable to the increase of this pest. From its exceedingly minute character, this mite often does a deal of damage before its presence is suspected. Vaporising with the XL All Vaporiser at intervals of a few days, or dipping the plants in some nicotine solution, will effect a cure; but in your case the mischief is already done. While too dry an atmosphere is injurious to Gloxinias, we do not recommend daily syringing, though in very dry weather it is beneficial. Rather than too much syringing it is better to maintain a certain amount of humidity by damping the stages on which the plants are stood.

FRUIT GARDEN.

RASPBERRIES ON ARCHES (J. B.).—On rich, deep soil some of the strong-growing varieties of Raspberries, such as *Superlative* and *Norwich Wonder*, will give a cane-growth of from 6 feet to 7 feet in a season; but grown on ordinary garden land they cannot be depended on to grow high enough to cover arches, like the *Loganberry* vine. Why not arches of Blackberries? These make a cane-growth of from 10 feet to 15 feet in ordinary seasons on good land. They seldom fail to give a good crop of useful, indeed, delicious fruit when quite ripe every autumn. The Parsley-leaved variety is the best.

SUMMER PRUNING FRUIT TREES (J. I. O.).—This consists in pinching all the shoots the tree makes (excepting the main leading shoots) at the fifth leaf (understand, every shoot, including all side shoots). From the shoots so stopped other young shoots will issue in due course. All these must also be pinched back, at the third leaf this time, and every subsequent growth these shoots may make in the course of the season must be pinched back at the third shoot in the same way; some of the shoots will probably have to be stopped three times. See "Gardening for Beginners" in this issue.

MISCELLANEOUS.

AUSTRALIAN PEPPER (T. B. F.).—We have not been able to find out what is meant by Australian pepper. The native Pepper Plant of Australia is *Piper Novæ Hollandiæ*, but whether Australian pepper is the product of that plant we are not able to say, neither do we know whether one pepper would be any more effective than another for the purpose for which you require it. It is probable that Cayenne pepper sprinkled about would drive the dogs away. By calling at your nearest drug store you could probably find out whether Australian pepper is still in commerce, or the chemist in charge might be able to recommend something suitable for the purpose. In the meantime a little wholesome correction to the dogs might have the desired effect.

NAMES OF PLANTS.—*Solent.*—Poison Ivy (*Rhus Toxicodendron*). It is a dangerous plant to grow, for if handled by some people it causes a form of blood-poisoning. —*Lieutenant-Colonel Prestbury.*—*Genista tinctoria.*—*Lewis.*—*Sedum Sieboldii.* The blue-flowered plant is a form of *Campanula gargarica.*—*A. S.-1.* *Lilium giganteum*—you are to be congratulated upon flowering this beautiful Lily; 2, *Eucomis punctata*, a South African liliaceous plant.—*C. E.-1.* *Geranium pratense*; 2, *Veronica longifolia alba*; 3, *Thalictrum glaucum*; 4, *Centranthus ruber (Red Valerian)*; 5, *Nepeta Mussinii*; 6, *Anaphalis Margaritacea.*—*Payd.*—1, *Taxus baccata pendula*; 2, *Helichrysum (Gnaphalium) lanatum*; 3, too small to name; 4, a *Labiata*, not sufficient material to name; 5, *Veronica meisa*; 6, *Epilobium nummularifolium.*—*W. C. S.*—*Malmesion Carnation Princess of Wales.*—*S. C. R.*—*Nepeta Mussinii.*—*Orchid.*—1, *Orchis maculata*; 2, *Thalictrum aquilegifolium*; 3, *Glyceria aquatica variegata*—it grows about three feet or more.—*M. G.*—*Coleuses*: 1, *Edith Sentence*; 2, *Diana*; 3, *Fantasy*; 4, *Gem*; the *Fuchsia* is *Gertrude Pearson*, and the Fern *Nephrolepis exaltata.*—*Lewis.*—*Viscountess Folkestone.*—*Many Years' Reader.*—1, *Mrs. E. Mawley*; 2, *Warrior* or *General Schablinski.*—*John Hopper.*—*Jules Margottin.*—*An Amateur.*—We believe the *Rose* to be the variety *Mme. Audot*, one of the very old tribe of *Rosa alba*.

SOCIETIES.

ROYAL HORTICULTURAL SOCIETY'S SUMMER SHOW.

(Continued from last week.)

SWEET PEAS.

Messrs. Carter and Co., Raynes Park, erected a beautiful triumphal arch of Sweet Peas, and, with a raised platform as a base, this subject was seen to advantage. The quality of the flowers was very good indeed, and the grouping was exceedingly pretty. Among some of the better things were Masterpiece, Mrs. Routzahn, Mrs. C. W. Breadmore, Queen of Norway, Marie Corelli, Elsie Herbert, T. Stevenson, Prince George, Mrs. Cuthbertson, May Campbell and Elfrida Pearson. This was a fine effort.

A splendid table group of Sweet Peas was shown by Mr. W. E. Alsen, Denmead, Hauts. Good colour and capital quality were conspicuous, although the bunches might with advantage have been more lightly arranged. Mrs. H. Sykes, Melba, Stirling Stent, Mrs. H. Dickson, Evelyn Hemus, A. A. Fabus and Winsome were the better sorts.

A dainty lot of Sweet Peas was staged by Messrs. H. Cannell and Sons, Swanley. This group included most of the newer and better varieties, and the flowers were attractively set up.

Messrs. Sutton and Sons, Reading, made a very wonderful exhibit of Sweet Peas, representing about one hundred and twenty bunches, set up in most attractive fashion. About seventy-two feet frontage was occupied by this very handsome exhibit, and all that was worth growing in Sweet Peas was seen here. A background of velvet, with arches

Mary (blue), Breadmore's Frilled Cream (cream), Audrey Crier and Elsie Herbert, all in excellent form and condition.

A number of vases of the better Sweet Peas were set up in the group of hardy flowers arranged by Messrs. Kelway, Langport. The flowers were large and well grown, and the varieties up-to-date. Miriam Beaver was very fine.

A particularly charming group of Sweet Peas came from Messrs. E. W. King and Co., Coggeshall, Essex. The blossoms were most attractively displayed, and the flowers were fresh, clean and highly coloured. Anglian Lavender, Elsie Herbert, Mrs. W. King, Gladys Burt, Nubian, Anglian Pink, Nettie Jenkins, Constance Oliver and Anglian Fairy were beautifully shown.

A pretty collection of Sweet Peas was staged by Messrs. S. Bide and Sons, Farham, Surrey. Baskets, artistic vases and a variety of receptacles were utilised to display these dainty flowers to advantage. Bertha Massey, Queen of Norway, Florence Nightingale, Edna Harland and R. F. Felton were among the good things in this group.

A small group of Sweet Peas was shown by Mr. W. J. Godfrey, Exmouth. The flowers were fresh and clean, and up-to-date varieties were shown. May Campbell, Mrs. Townsend, Masterpiece, Elfrida Pearson and Juliet were the better varieties.

A very large collection of high-quality flowers was shown by Sir Randolph L. Baker, Bart, M.P., Ranston, Blandford. Remarkably fine were the blooms, and they were shown in wonderful variety. They might very easily have been more effectively set up; there was too much blank space at the back of the group. Mrs. Cuthbertson, Eric Harvey, Dorothy, Princess Victoria, Doris Usher, Audrey Crier, Lavender George Herbert, T. Stevenson and Mrs. W. J.

Enchantress, White Perfection, Scarlet Glow (grand colour), Mrs. T. W. Lawson, Enchantress, Beacon, Governor Roosevelt, Mrs. W. C. Ward, Melody, Cardinal and a very promising fancy shown under the name of Seedling No. 1. Messrs. Stuart Low and Co., Enfield, set up a fine exhibit of Carnations in the manner peculiar to this firm. With appropriate foliage the effect was good. Of the Malmaisons, Old Blush, Irene, Lady Mary Hope, Lady Coventry, Calypso, Sault, Princess of Wales and Martin R. Smith were first-rate. There were some fine vases of the Perpetual-flowering Baroness de Brien (a beautiful blush pink sort).

Messrs. W. Wells and Co., Limited, Merstham, Surrey, showed Carnations in their group of miscellaneous plants. White House, Lady Algy, Dorothy Gordon, R. F. Felton and Scarlet Glow were seen in good form.

Mr. J. D. Webster, Chichester, had a small group of Carnations in pleasing variety. Lady Wolverton was noteworthy.

A pretty group, arranged on the ground, was set up by Messrs. John Peed and Son, West Norwood, S.E. The arrangement might have been vastly improved, but the flowers were fresh, clean and of good quality.

Carnations were nicely shown by Mr. H. Lakeman, Thornton Heath, Surrey. Miss Willmott, Thomas & Becket, Lieutenant Shackleton, Lady Hermione, Amy Robsart, Leslie and several well-known Perpetual-flowering kinds were in evidence.

A splendid bank of Malmaison Carnations was put up by Mr. W. M. Gott, Trenythron, Par Station, Cornwall. They were a fine lot, and included, among others, Princess of Wales, Madge Hodgson, Mrs. Trelawney, The Queen and Monk.

Carnations were also set up in another comprehensive group by Messrs. R. H. Bath, Limited, Wisbech. They were all border sorts, and were a beautiful series. Nene Beauty, Safrano, Unique, Gondolier and others were noteworthy. There were also a good number of Perpetual-flowering sorts.

Mr. Charles Blik, Hayes, Kent, had a pretty exhibit of very fine Carnations. They were set up with "grass" as an embellishment, and looked very prettily. Pater, Cyclops, San Remo, R. Morton, The Nizam, Salome, May Day and King George were all very fine.

A splendid table group of Carnations was set up by Mr. H. Burnett, Guernsey, representing Malmaison and Perpetual-flowering varieties. R. F. Felton, Mikado, Mrs. H. Burnett, Mrs. Tatton, Enchantress, Mandarin, Mrs. W. B. Clode, Duchess of Devonshire and Marmion were well shown.

Mr. C. Engelmann, Safron Walden, Essex, also staged Carnations splendidly in a table group. Handsome blooms in vases and stands in variety were shown in beautiful condition, and this grower well maintained his reputation. Elektra, May Day, Rex, Carola, Lady Northcliffe, White Star and Sunstar were all good.

A very fine exhibit of Carnations was shown by Mr. James Douglas, Edenside, Great Bookham, Surrey. The varieties shown were the hardy border kinds, and they were distinctly good. Mrs. Fenton, Greyhound, Mandalay, Miss Willmott, John Ridd, Mrs. R. Gordon, Lord Nelson, Mrs. Henwood and Mrs. Elliot Douglas were a few of the more lovely things sent by this well-known raiser and grower.

STOVE AND GREENHOUSE PLANTS.

From Mr. W. J. Godfrey, Exmouth, came a capital collection of well-grown show and fancy Pelargoniums, set up in attractive fashion. Lady Doreen Long, Bicton, Mrs. A. Wootten, Bystock H. S. Davy and King George V. were noteworthy. Sweet-scented Pelargoniums were also represented in a small group from the same firm.

British Ferns were represented in considerable variety by Messrs. H. B. May and Sons, Edmonton. These beautiful native Ferns were shown in the pink of condition, and could not have failed to please visitors. Of the better things, *Polystichum aculeatum gracillimum* Druryi (a lovely plant), *P. angulare divisilobum* capitatum, *Athyrium Filix-femina gemmatum* and *Scopolopodium vulgare crispum Robinsonii* were specially good sorts.

Ferns and Cacti made an interesting exhibit as shown by Mr. H. N. Ellison, 5 and 7, Bull Street, West Bromwich. This was a very representative group, and many species were in evidence. The plants were of much interest to the public.

Ivy-leaved Pelargonium Queen Mary was shown in a table group by Mr. H. Hensley, Crawley, Sussex. The plants were freely-flowered, and were also in good health.

A pretty group of *Araucaria exaltata gracilis* was set up by Messrs. Carter, Raynes Park, S.W. The plants were well grown, being feathered with foliage down to the rim of the pots.

Gloxinias and Streptocarpus were well shown by Messrs. John Peed and Sons, West Norwood, S.E. These plants had fallen with the staging in the early morning, and had come through the ordeal very well.

Cut Zonal Pelargoniums were exhibited by Mr. Vincent Slade, Taunton, Somerset. Large and handsome bunches of popular sorts were shown.

A group of miscellaneous flowering plants was staged by Messrs. J. Veitch and Sons, Limited, Chelsea, and although the plants had suffered by the fall of the staging in the morning, they looked very well. Malmaison Carnations, Begonia Lucerne, Achimene Rose Queen, Cannas, Streptocarpus, Calceolaria Burbiidgei and Solanum Wendlandii were a few of the better things in this exhibit.

Hardy Ferns were well shown by Mr. Amos Perry, Enfield. The plants were pleasingly disposed among boulders of rocks and were made to appear quite natural in their surroundings. Many fine specimens were in evidence, including *Polystichum angulare* Gow's Hybrid.

A GROUP OF ROSES SHOWN BY MESSRS. PAUL AND SON, CHESHUNT, HERTS, AT THE HOLLAND PARK SHOW.

of Smilax and Asparagus and columns of Sweet Pea blossoms, made a really grand effect. An immense array of vases, filled with high-quality flowers, made one of the best efforts of this great firm. The best kinds were Southcote Blue, Doris Usher, Helen Grosvenor, Mrs. A. Ireland, Sutton's Queen, Sutton's Mauve on Cream, Brilliant Scarlet, Sutton's Scarlet Crimson and Sutton's Rose Pink.

Quality and effect were represented in the marvellous display of high-class Sweet Peas by Messrs. Dobbie and Co., Edinburgh. This firm has achieved such distinction in the development of the Sweet Pea that we naturally look to them to do something more meritorious than other growers, and in this exhibit we were more than pleased. Pyramids, vases, &c., represented these flowers superbly, and each vase contained blooms of the very best. Special mention must be made of Mrs. Cuthbertson (clear rose pink standard, white wing flushed pale rose). Four or five blooms could be seen on each stem. Dobbie's Scarlet (scarlet, toned cerise), Brunette (rich, deep mahogany self), Lavender George Herbert (Dobbie's stock—plenty of fours, blush lavender) and Decorator (old rose and terracotta) were among many others that were superb.

Mr. J. D. Webster, Chichester, had a capital lot of Sweet Peas in charming variety. Juliet, Senator, Selected White Spencer, Mrs. C. W. Breadmore, Thomas Stevenson, Elsie Herbert, Helen Grosvenor, Masterpiece, Prince Olaf, Mrs. Heslington and Mrs. Charles Foster were a few of the better kinds in this good collection.

Mr. Charles W. Breadmore, Winchester, staged a magnificent group of Sweet Peas, exhibiting about one hundred and forty vases, including all the newest and best varieties in commerce. The flowers were set up most attractively, were well coloured and of good quality. Varieties deserving special mention were Aggie Elder (rosy cerise), Princess

Unwin were a few of the better things in this truly grand lot of flowers.

Mr. James Box, Lindfield, Sussex, had a grand mass of Sweet Peas, exhibiting the better and well-known sorts. We think this exhibit would have looked better had it been less crowded. Mrs. Gibbs Box, Money-maker, Arthur Unwin, Barbara, Countess Spencer, Audrey Crier and James Box were worthy of mention.

A large and comprehensive collection of Sweet Peas was shown by Messrs. John K. King and Sons, Coggeshall, Essex. All the good things were to be seen here, but the general effect was not so good as it might have been, owing to the crowded state of the vases. America Spencer, Doris Burt, Rainbow Spencer, Marie Corelli, Mrs. A. Ireland, Thomas Stevenson, Melba and Prince Edward of Wales were very charming.

A useful collection of Sweet Peas was put up by Mr. Marshall Y. Green, Eynsford, Kent. Novelty and well-known sorts of sterling merit were to be seen in excellent form and condition, high quality characterising all the flowers. Mrs. C. W. Breadmore, Orion, Edna Unwin, Barbara, Nellie Maslin and Marchioness of Tweeddale were exceptionally good.

Mr. Robert Sydenham, West Birmingham, put up an exhibit of an interesting character, staging handsome bunches of the more popular varieties. Lihan, Mrs. T. W. Warren, Orion, Maud Holmes, Lady Evelyn Eyre and Elsie Herbert were all good and well grown.

CARNATIONS.

A wonderfully fresh and bright exhibit of Carnations was staged by Mr. G. Lange, Hampton. Stately vases were artistically arranged with very clean and beautiful blossoms. The more noteworthy sorts were Rose Pink

EDITORIAL NOTICES.

Every department of horticulture is represented in **THE GARDEN**, and the Editor invites readers to send in questions relating to matters upon which they wish expert advice.

The Editor welcomes photographs, articles and notes, but he will not be responsible for their safe return. All reasonable care, however, will be taken, and where stamps are enclosed, he will endeavour to return non-accepted contributions.

As regards photographs, if payment be desired, the Editor asks that the price required for reproduction be plainly stated. It must be distinctly understood that only the actual photographer or owner of the copyright will be treated with.

The Editor will not be responsible for the return of artistic or literary contributions which he may not be able to use, and the receipt of a proof must not be taken as evidence that an article is accepted. Publication in **THE GARDEN** will alone be recognised as acceptance.

Offices: 20, Tavistock Street, Covent Garden, W.C.

NOTES OF THE WEEK.

Sweet Peas in Dumfriesshire.—Among the considerable number of places in Dumfriesshire where Sweet Peas are cultivated in the most successful way is Castlemilk, Lockerbie, the garden of Sir R. W. Buchanan-Jardine, Bart., where his gardener, Mr. John Jeffrey, grows them well. Many of the stems this year have been 22 inches long with flowers in proportion. Senator Spencer, Clara Curtis, May Campbell, Mrs. C. W. Breadmore and many others have been exceptionally fine. Deep and thorough cultivation is practised at Castlemilk, and the reward is seen in the shape of magnificent flowers.

Roses and Sweet Peas at Purley.—One of the best local shows it has been our privilege to see was held by the Purley Rose and Horticultural Society on Saturday last in the grounds of Upper Woodcote, the residence of the president, Mr. William Webb. The Roses, notwithstanding the early season, were exceptionally good, and competition was very keen indeed. Sweet Peas, too, were also good, though in a few instances the effect of the hot weather was too apparent. Seeing that Purley boasts a road nearly a mile in length, bordered on each side with rambler and dwarf Roses, it is not surprising that these flowers are popular in the locality. Bordering another road near by is a beautiful herbaceous border, a feature that might well be adopted in many so-called garden suburbs.

Mulberry with Two Kinds of Flowers.—At a recent meeting of the scientific committee of the Royal Horticultural Society, Mr. Luxmoore of Eton wrote regarding a Mulberry in his garden which showed a tendency towards dioecism. The staminate flowers were all upon one part of the tree, with but few pistillate ones among them. The pistillate flowers were mostly upon the other branches, and the separation of the two forms of flower was almost complete upon the different parts of the tree. Mr. Wilks said that a tree in his garden always produced the two forms on separate branches, and the leaf colouring was quite distinct, and had been so for many years. Mr. Hales said the same was true of two trees in the Chelsea Physic Garden, and was constant. It would be of interest to see the behaviour of plants raised from cuttings from the distinct parts of the trees.

Flowers at the General Post Office.—It will be of interest to a great many of the general public to learn that among the employés at the General Post Office there are many enthusiastic amateur gardeners, and that at least two distinct horticultural societies exist there. One is the St. Martin's Horticultural Society, and the other the Central Telegraph Operators' Society. Both held their summer shows last week at the General Post Office, and it was interesting to see the perfection

to which flowers, fruits and vegetables had been brought by the men and women who deal with our telegrams and letters. Sweet Peas, Violas and Roses were perhaps the strongest features, though fruit was exceptionally good in the Telegraph Operators' show. At the St. Martin's Society's show we were particularly pleased with a basket of flowers shown by a lady member. This was composed of crimson Roses, blue Hydrangeas and Ferns, and was almost equal to anything of its kind we have ever seen at the "National" shows in London.

The Wild Thyme as a Rockwork Plant.—Although the varieties of our common wild Thyme (Thymus Serpyllum) cannot be assigned a place among the choicest of subjects for the rockwork, yet some of the forms are very beautiful when grown in this way. The rich-coloured kinds, such as coccineus and splendens, are the more striking, but the white variety albus possesses a quiet beauty of its own, and affords a direct contrast to those of richer hues. To the beginner in rockwork planting, especially such as aim at effect rather than the rarity of the specimens, these Thymes can be recommended, as, under anything like favourable conditions, they are, given a sunny spot, sure to do well. Few plants will stand drought better. Again, for the taste which now prevails of forming paved walks and planting subjects of humble stature between the interstices of the stones, few plants are more fitted than Thymus Serpyllum and its varieties, as they will put up with a reasonable amount of treading on, and, when slightly crushed, their pleasing perfume is most pronounced.

Good Examples of Summer Bedding.—The gardens at Hampton Court have long been celebrated for the excellence of their summer bedding, as well as for the pleasing and unorthodox combinations, that are always to be found there. With so many striking examples to select from, and the fact that very few persons see eye to eye in such matters, it is difficult to select the very best, but the following appealed strongly to us, both from the point of beauty and novelty: (1) A groundwork of the white-striped *Holcus mollis* variegata and dwarf *Nigella*, over this good-flowered examples of *Verbena* Miss Willmott, while standing above all the rest were the feathery plumes of the lilac pink coloured *Astilbe* Venus, the whole being edged with *Echeveria secunda* glauca. (2) A carpet of the dazzling white *Calocephalus* (Leucophyta) *Brownii*, dotted over with tall plants of the same, and of the white variegated *Phlox* Comtesse de Jarnac, the entire bed being sprinkled over with the pretty double pink *Begonia* Major Hope. (3) A close groundwork of the white *Koeniga maritima*, over this *Begonia* Major Hope, with a few erect 2-foot plants of *Calocephalus* *Brownii*.

CORRESPONDENCE.

(The Editor is not responsible for the opinions expressed by correspondents.)

Rose Pink Roamer.—We hear very little of the single wichuraiana Rose Pink Roamer nowadays, though it is more worth growing than some of the Roses of climbing habit which are being showered upon us. It has been in cultivation for a considerable number of years, and has proved a very satisfactory one for growing on pillars or walls, or up among the branches of trees. On a tall tree stump here it is very good this season, even finer than last year, and giving a great number of its deep pink, lighter-centred single flowers. Although single, these last considerably longer than might be expected, especially in a cool season. It is remarkably free in its growth, and soon makes long, pliant branches which lend themselves to any system of training required.—S. A. DUMFRIES.

The Day Lily.—This good, well-known plant, *Hemerocallis fulva*, is as yet unsurpassed in its own way, though we have had quite a number of newer *Hemerocallis* introduced since its time. Its tawny-coloured flowers look very handsome and showy, though not brilliant, when on a plant three feet or so across, and the constant succession of flowers makes it a most valuable border plant, though the individual blooms are somewhat short-lived, like those of the other species of *Hemerocallis*. In moderate soil it will attain a height of about four feet, and is then a striking ornament of the garden in late June or July. Some prefer the double flowers of the variety called *Kwanso*, and others, again, the form *variegata*, with variegated leaves; but I must confess to a distinct preference for *H. fulva* itself. It is sometimes called *H. disticha*, and appears to be a native of both Europe and Temperate Asia.—S. ARNOTT.

Lord Bacon and Gardens.—At the recent unveiling of the statue to this great philosopher, allusion was made to Gray's Inn Gardens, in which Bacon took much interest. The account-books of the Inn give items of expenditure and money laid out in 1598 for their arrangement. The gardens and walks remain about the same to-day, and Charles Lamb spoke of them as the "best gardens of any of the Inns of Court." Gardening art was beginning to assert itself, and geometrical designs were coming into fashion in the gardens at Nonsuch, Theobald's and Hampton Court. Bacon seemed to condemn this conventional arrangement and the making of "figures with divers coloured earths." Nonsuch was specially famed for its gardens and lawns. Broad terraced walks, long, varied banks and alleys of trellis-work diversified the prospect, and it is said Lord Bacon had this picture in view when he wrote his "Essays of Building and of Gardens." Little indeed remains of Nonsuch, once the fairy-like structure of Tudor days, wherein architectural art was employed in such a skilful manner that the palace became a byword for quaint and original beauty. Antiquarian interest has been lately revived in the excavations of the ground, which will possibly identify the site of some of the inner courts or the banquet-house. Wimbledon House (the home of the Cecils) was also famed for its gardens, and Henrietta Maria, Queen of Charles I., took great interest in the gardens. Trees from France were transported thither, and in later times John Evelyn, so great an authority on horticulture, was consulted as to the arrangement of the Wimbledon gardens. We still have evidence of the story of gardening from past days,

when the market-gardens of Bermondsey, Battersea and Fulham, places once associated with fruit and vegetable culture, were much used and frequented. It was a common thing in the early years of the nineteenth century for the gentry to drive out to Battersea Fields, where Melons, Mushrooms and Radishes could be bought, products for which the light soil and marshy land were favourable.—S. W. K.

The "Breaking" of English Iris.—I have for some years past been carefully growing on a very pretty mauve English Iris (*I. Xiphium*), which was an entire self without any suspicion of a splash of any darker shade. It appeared as a chance seedling, and I thought I had got hold of a prize. To my intense disgust, three out of my little stock of fifty have this year come "broken," as we say in Tulip lingo; that is to say, each of them is very much marked with pale rosy purple splashes, and the ground colour of the whole is of a decidedly darker shade. I have been in correspondence about it with my old friend, M. van Tubergen of Haarlem, and he tells me that "they all do it." This is news to me. I thought the peculiarity of breaking was confined to the Tulip. I have looked up *I. Xiphium* in Mr. W. R. Dykes' excellent little book on Irises in Present-Day Gardening, but he does not mention it. The dark garden forms which I happen to have do not seem to do it, nor yet the white *Mont Blanc*. Can anyone throw light upon this peculiarity?—J. J.

Showing Daffodils.—A word, please, Mr. Editor. I think your correspondents are a bit muddling things up. The late Lord Chamberlain once got up in the Commons and said, "I am not an agricultural labourer." I believe it tickled the House immensely. Now that is what a lot of show flowers say, and what a lot of garden flowers say. There are, of course, many mixomycetic ones (good hard word that, eh!) which are neither fish, flesh, fowl nor good red herring. They are lucky dogs, right either way. But a show flower is a show flower, and its first purpose in life is to be sent to shows; so with a garden flower, its prime object is to make an effect in the garden. They are two distinct things, and must be treated differently and thought of differently. This must happen directly a plant comes into the select circle of "florist flowers." It cannot be helped, although I know it is distressing to our-like-them-as-they-grow-naturally friends. All I am prepared to say now is that I do not think anything should be added to or attached to a flower when it is exposed on a show-board. The *débutante* does not go to Court with her curling-pins in her hair. When the National Daffodil Society comes into being, these things will be all straightened out, but not till then. At present Daffodilism is a community with no organisation and no leader.—J. JACOB.

— I should like to correct what is evidently a slip of the pen or a printer's error in "J. E. D.'s" letter on page 350. He says I admitted that I was "almost converted" to the little discs; I have done nothing of the sort. In the case I referred to on page 315 the disc was so cleverly placed that I was "almost deceived"; but converted, no, certainly not. "J. E. D." sounds the right note when he says that if we allow faking we encourage the wrong sort of flower and knowingly mislead (I would say "deceive") the public; and "A Gardener," I think, hits the right nail on the head when he suggests the reason for so few writing against faking is because there are too many exhibitors who have fallen to the temptation of just pressing out an *Engleheartii* cup that was not

quite flat enough, or coaxing a refractory petal into temporary flatness with a paper disc; and because I have few supporters among the exhibitors is the strongest of reasons why someone should voice the opinion of those who are not exhibitors. The public, once bit, will certainly be twice shy, and I trust that by thoroughly ventilating the subject in good time we may be able to prevail upon the various Daffodil societies to do all they can to encourage the honest flowers.—W. A. WATTS.

— Both Mr. Watts, page 338, and "J. E. D.," page 350, have assumed that my remarks had reference to "bad" and "feeble" flowers, though I never used those terms. I had in my mind what are normally good show varieties only. I used the term "artistic" faking with intention, for I do not consider it is "artistic" to leave a paper collar or support on the bloom once it is set up on the show-bench. It is not that it is "dishonest" (in spite of Mr. Watts), but merely inartistic; and, as far as my experience goes, the practice is safe to be penalised by the judges when used in competitive exhibiting. I cannot help thinking it is regrettable that Mr. Watts should use the term "dishonest" so freely in commenting on the practice of those who do not happen to agree with his own particular methods!—A SMALL EXHIBITOR.

The Double Standard in the Sweet Pea.—It would be interesting to learn from what point of view the National Sweet Pea Society regards the presence of the twin or duplicated upper petal to which the phrase "double standard" has been given. Judged by the numerous, almost sensational, disqualifications at the recent show from this cause alone, it would appear that it were regarded as a defect, something to be discouraged, were it not for the fact that in at least three classes such flowers were admissible—were, indeed, asked for by the society. Hence the point of view is not a little obscure. If, as some appear to imagine, this duplication of petals is wholly the outcome of excessive feeding, a stepping-stone to grossness and the spoliation—partial or otherwise—of a graceful and beautiful flower, then I think the majority of Sweet Pea lovers would back the society up in a rigid adherence to a condition—however sweeping and drastic that condition might be—in any endeavour to stem the tide of any such catastrophe. But the fact that this same duplication of upper petals is more or less prevalent in flowers grown in the poorest of soils, and is seen in sprays with not more than two flowers thereon, would appear to suggest that it is but a stage, a phase, in the evolution of a flower which has hitherto displayed a tendency to variability in its floral parts. Already the waved flower has become quite a craze, and has done not a little probably to create that greater popularity which the flower now enjoys. The coming of the duplicated standard may be but a move to more complete doubling of all the parts of the flower, and, if so, who can gauge the end? What saddened one most of all at the recent show was to see the finely-grown, well-displayed groups disqualified one by one, though it was some satisfaction at least to know that big men and little men—top-sawyers and pitmen—all suffered alike.—E. H. JENKINS. [We think the position of the National Sweet Pea Society over this matter is perfectly clear. The committee recognised that the double standard had come to stay, and provided three classes for it, but rigidly, and we think rightly, excluded it from the other classes. Whatever the merits or otherwise of the double standard may be, the judges were bound, on the terms of the schedule, to disqualify the exhibits they did —E.N.]

Rose Lady Gay for Towns.—I enclose herewith a photograph of the climbing Rose Lady Gay. It is grown on a wire arch, which it completely covers. I estimate that at the time of writing it is bearing about five hundred trusses of bloom, the rich cherry pink of which is relieved by the beautiful glossy foliage. The successful growth so near London should encourage the suburban amateur who desires such a form of garden decoration. — F. W. MILTON. [Unfortunately, the photograph was not suitable for reproduction.—Ed.]

An Interesting Shrub (*Philesia buxifolia*).—This exquisite little shrub is frequently the despair of would-be cultivators without a cool house in which to grow it; but there are some who can, and do, succeed with it under other conditions. It is a success with some growers in the warmer parts of England and Ireland; but there are some who are equally successful with it in several parts of Scotland, always, however, with some precautions against severe weather. The writer knows of several Scottish gardens in which it is well grown with the protection of a hand-light, the top of the latter being taken off during most of the summer, but replaced for winter, with a little tilting in mild times. The best plant I have seen is in the garden of Mr. James Davidson, Summerville, Dumfries, where it fills the whole of a hand-light of medium size—about two feet square. It has been in the same place for several years and flowers with great freedom, giving an abundance of charming red *Lapageria*-like flowers, which look so well among the deep green leaves. At Summerville it is cultivated in a shady position, and in peat, loam and sand.—S. ARNOTT.

Echium Wildpretii.—I am sending a photograph of this handsome and striking-looking plant. It is a biennial and, like several other species of the same genus, a native of the Canary Islands, being originally raised from seed sent by Mr. Wildpret, Curator of the Botanic Gardens, Orotava, Teneriffe. Owing to the difficulty sometimes experienced in its cultivation, the following cultural notes may be of value: The seed is best sown during the months of July or August; it soon germinates. When large enough, the young seedlings should be pricked singly into 2½-inch pots. When the roots show through the compost they should be repotted into 3-inch or 4½-inch pots, according to the size of the plants, and they should pass the winter in pots of this size. At this stage they give little trouble if placed in a position well up to the glass, in a light pit, or on a greenhouse shelf. During winter they should be kept fairly dry at the root. On the turn of the year, if well rooted, they should be repotted into 6-inch or 7-inch pots, using a compost of good medium loam, with the addition of some leaf-soil, and plenty of coarse sand or old mortar rubble to keep the whole open. At this stage trouble generally starts, for, unless great care is exercised, each successive potting results in the loss of a few plants. They may be flowered in 6-inch pots; but if large specimens are required, they must be potted on into 8-inch pots. This should be done in time to get them well established before winter, as that is the most critical stage in their cultivation. At this stage they are striking objects, the plant consisting of a huge rosette of beautiful silvery grey leaves. During the second winter they require great attention to manage them successfully. As before, they should have a light, dry position, and no more water applied at the roots than is necessary to keep them from shrivelling. Early in the New

Year the stems begin to elongate, until, if everything has gone all right, they may attain a height of 2½ feet to 4 feet, nearly half the length being composed of the flower-spike. When in flower, which is usually about the beginning of May, they are very handsome with their great spires of beautiful rosy red flowers. In spite of its beauty it is not likely to become a popular garden plant, except by the few who love to cultivate choice and difficult subjects.—J. C.

FORTHCOMING EVENTS.

July 23.—National Carnation and Picotee Show at Vincent Square. Brighton and Sussex Horticultural Show (two days).

A STATELY BUGLOSS (*ECHIAM WILDPRETHI*).

July 24.—Leamington Flower Show (two days) Normanby Flower Show (two days). Bishop's Waltham Flower Show. Royal Botanic Society's Meeting. Hayward's Heath Flower Show. Lyndhurst Flower Show. Feltham Flower Show.

July 25.—St. Ives (Hunts) Flower Show. Ramsgate Flower Show. Killarney Sweet Pea Show.

July 26.—Huddersfield Horticultural Show (two days). Cheadle Flower Show (two days).

July 27.—Fife and Kiross Flower Show.

THE GREENHOUSE.

EAST LOTHIAN STOCKS.

HOW TO GROW PLANTS IN POTS.

THESE are few plants that are quickly raised from seeds more satisfactory in every way than East Lothian Stocks grown in pots for the embellishment of the conservatory in springtime.

Owners of comparatively cool conservatories or greenhouses cannot do better than raise a few seedlings for the purpose named. Four fine distinct colours may be obtained, and plants in 7-inch pots measuring nearly eighteen inches in diameter can be grown without difficulty. The fragrance is delightful, and the flowers last for a considerable time in a fresh condition. A fair percentage of double flowers may be had, but the single blossoms are equally fragrant and attractive. For grouping with other kinds of plants the singles are the most effective. They are generally the strongest plants, in the seedling stage especially, the doubles being dwarfer and of a more compact habit, and do not look as robust.

Sowing the Seeds.—Some cultivators sow the seeds in large pots, and do not transplant the resultant seedlings at all. This method I do not favour. I prefer to sow the seeds in a deep pan filled with nice loamy soil late in June or during July. The latter date is best for the South and the former date for the Northern Counties. The seedlings must be grown under quite cool conditions. Transplant them singly in 3-inch pots when they possess three or four rough leaves; use the soil in a medium state of moisture, and press it down a little with the fingers. Add a small quantity of old mortar rubble to the compost. The early transplanting will induce the formation of many fibrous roots, which is a great advantage. Do not allow the plants to become pot-bound, but re-pot them the moment a fair number of roots can be seen around the outside part of the ball of soil. At each repotting use the compost in a rougher state, and also make it firmer. Some plants will branch out naturally; others will require the main stem stopped. Keep the plants in a cool, airy frame until January, then transfer them to the greenhouse, and here again admit air to them freely on fine days. Feed the plants with plenty of diluted liquid manure directly the flower-spikes show.

AVON.

CALCEOLARIA BUTTERCUP.

THIS is a charming and graceful subject for the conservatory and cool greenhouse, attaining a height of 1½ feet to 2 feet. It is derived from the intercrossing of *C. Clibranii* and *C. Golden Glory*, and was raised by Messrs. Veitch of Chelsea at their Langley nursery. As would be expected from such parents, the flowers are yellow, and from a batch of seedlings a variety of shades are obtained, some are beautifully spotted, especially on the under sides. It quickly attains flowering size, lasts in bloom for a long period, and makes a splendid decorative plant. Seeds should be now sown in well-drained pans, and placed where the sun cannot reach them, when germination will soon begin. As the seedlings become large enough to handle, each may be given a separate receptacle, and should be potted on as required till they reach the flowering size, viz., pots 7 inches in diameter. A suitable rooting medium consists of fibrous loam three parts, and well-decayed leaf-mould one part. Grow on in cold frames, keep a sharp look-out for green fly,

POTENTILLA ALBA, A FREE-FLOWERING PLANT FOR THE ROCK GARDEN.

and never allow them to suffer from drought, when a healthy batch of plants rather out of the common run will be the result. S.

THE ROCK AND WATER GARDEN.

POTENTILLA ALBA.

IN the large Cinquefoil family there are many beautiful plants suitable either for the herbaceous border, like *P. argrophylla* and its numerous forms, or for the rock garden. For the latter purpose there are several choice dwarf-growing species that are very useful and ornamental. Among the latter may be included *P. alba*, which is here illustrated growing on a ledge and flowering freely during the month of April. Its home is in the Alps and Pyrenees, and it is a very attractive plant, with silvery leaves having a silky down on the lower sides. Very dwarf and not too rampant, the white, Strawberry-like flowers each about an inch in diameter, with a dark orange ring at the base of the petals, are freely produced. Somewhat resembling the above is the Pyrenean *P. alchemilloides*, with narrower leaflets, also covered with silky hairs on the under side of the leaf. It grows slightly taller and has rather smaller flowers, but produced in greater profusion. Among the yellow-flowered kinds, one of the freest is *P. nevadensis*, which barely reaches a height of 2 inches or 3 inches. It is a very compact-growing plant, with small, hairy leaves if planted in poor, sandy soil; but if put in richer ground it readily responds, and the flowering branches elongate to a greater extent. As a plant for growing in pans it is very useful for the alpine-house, producing plenty of flowers over a long period. Another pretty little plant is the European *P. aurea*; but the Himalayan form, *P. aurea* variety *ambigua*, has much larger, clear

yellow flowers on a dense carpet of foliage. All the foregoing are among the easiest of plants to grow, succeeding well in any sunny, well-drained position or on a rocky ledge. They all produce seed, by means of which they can be increased, as well as by division. Besides the plants mentioned there are numerous others, like *P. nitida*, which come into flower rather later.

LITHOSPERMUM PROSTRATUM CÆRULEUM.

ONE of the most popular inhabitants of the rock garden, *L. prostratum*, is a general favourite with all. Forming a spreading carpet of intermingled twiggy branches, clothed with evergreen foliage, it is a valuable plant for either the border or the rock garden. Planted on a rocky ledge, the shoots may be allowed to fall down the sunny face of the rock, thus forming a curtain of dark green, studded in spring with beautiful rich gentian blue flowers. For wall gardening it is an ideal plant, soon forming large hanging tufts of great beauty. As a pot plant it is charming, doing well in pans, and helps

to furnish the alpine-house, making quite an attractive feature. It is not particular as to soil, although it enjoys a good depth of light, rich loamy soil with plenty of humus in it. Although it is said not to like lime in any form, I have seen a large plant quite happy for many years in a bank mainly composed of limestone and mortar rubbish. *L. prostratum*, however, dislikes transplanting when of any size, and takes a long time to recover, so that it is always best to start with young plants and await their development. The plant illustrated, *L. prostratum cæruleum*, has flowers of a lovely pale blue colour, and is also well known under the name of Heavenly Blue. It is a charming companion for the type where both can be grown; but in some gardens the dark blue succeeds best where the light one fails, while in other gardens, again, the reverse is the case. Both may be propagated by means of cuttings in summer, selecting the short young growths with a heel and putting them in sandy loam in a close frame. W. I.

TREES AND SHRUBS.

THREE BEAUTIFUL SHRUBS.

A Useful Mock Orange.—In early summer we are accustomed to seeing many of the Mock Oranges in flower, lading our shrubberies with their wealth of flower and perfume. *Philadelphus grandiflorus floribundus* is a variety which for freedom of flowering and size of flower would be difficult to excel. It forms a symmetrical bush, throwing up straight, strong growths, from which next year's flowers will be issued, and perhaps their vigour will be more clearly understood when I state that many of the leaves, which are cordate in shape, are over seven inches long by 5 inches in width, necessitating the shortening back of the more vigorous ones to expose more clearly the sprays of blossom so freely produced. These measure from 8 inches to 12 inches long, and average as many blossoms, produced in pairs, each flower being opposite the other. The blossoms are pure white, slightly cup-shaped, single in form, with a bunch of golden anthers in the centre, and measure over two inches in diameter. The flowers are slightly scented, quite sufficiently so to make them agreeable.

A BLUE-FLOWERED ROCK PLANT, LITHOSPERMUM PROSTRATUM CÆRULEUM.

Escallonia langleyensis.—What a delightful shrub this is at the present season, whether seen as a bush specimen in the shrubberies or loosely trained to a wall or balustrade, where the countless flowers are portrayed to the fullest and best advantage. Though not large, the individual blooms are, nevertheless, remarkably showy, being of a rich shade of red, which contrasts with the shining foliage. Apart from its special characteristic, it makes one of our handsomest evergreens at other seasons of the year, and is quite hardy. It deserves planting freely. It is the result of a cross between *Escallonia macrantha*, a species with evergreen foliage and crimson-coloured flowers, and *E. philippiana*, a deciduous species with white flowers, and also wonderfully free and showy, though the flowers are not nearly so large as those of the hybrid.

Helianthemum formosum.—The mere mention of the name *Helianthemum* or their ally *Cistus* is sufficient proof of the beauty of the plant, and a collection of these forms one of the most interesting features in the hardy flower garden. That some are none too hardy I am well aware; still, they are readily increased by cuttings, and a few may always be held in reserve. The one above is now making a brilliant display and is flowering profusely, both planted among the stones beside the garden path, and in the fore part of the shrubberies, the numerous yellow flowers with the dark, almost pure black, blotch at the base of each petal rendering it most attractive. When planting any of the numerous varieties, a sunny, open site should always be chosen, which, with an open, porous soil, will suit their requirements to a nicety. E. BECKETT.

ROSE GARDEN.

NEW ROSES AT THE "NATIONAL" SHOW.

As usual, great interest was centred in the tent set apart for new seedling Roses at the National Show held last week, and it must be admitted that some very beautiful novelties were staged. Messrs. Cocker and Sons of Aberdeen unanimously obtained a gold medal for

Mrs. Andrew Carnegie, a most superb bloom, which some of the judges felt deserved a special award, apart from the blue ribbon of the Rose world. It is a seedling from Frau Karl Druschki, crossed with the old Rose *Niphotos*, and never at its best have I seen *Niphotos* with larger petals. The colour is the palest lemon white imaginable and the formation of the greatest beauty, with a fine globular centre and huge outer petals. Another gold medal was awarded to

Old Gold, a wonderfully coloured flower of the form of Mrs. Alfred Tate, but with the intense colouring of the *Eschscholtzia*, with more scarlet orange even than that. This lovely Rose was raised

by Messrs. S. McGredy and Son, Newtownards. When this variety and *Mme. E. Herriot* are on the market, our gardens will receive two lovely gems from a colour point of view.

No fewer than nine silver-gilt medals were awarded, one each to the following varieties:

Mrs. C. Reed, shown by Messrs. Lowe and Shawyer. It is a flower of the style of *Clara Watson*, but evidently of stouter build, and with a lemon-like shading.

Queen Mary is a really lovely and quite unique colour. If one can recall the old *Rose Luciole* it may best describe it to say it has many of the charms of that variety, but the buttercup yellow shading gives it a most wonderful hue, and I should not be surprised to find it in the front rank of decorative Roses. This fine variety was from Messrs. A. Dickson and Sons, Newtownards.

Mrs. C. D. Hunting, from Messrs. Hugh Dickson, Belfast, is a fine Rose. Perhaps to say it comes between *Arthur R. Goodwin* and *Mme. Ravary* would well describe it. Its petals are very firm, and it promises to be a good bloom to stand wet.

William Cooper, also from Messrs. Hugh Dickson, is a fine flower, but rather lacking in colour. Perhaps it is nearest to *Marquise Litta*, but with an orange hue.

Mrs. R. D. McClure, also from Messrs. Hugh Dickson, is a very pleasing shade of pink, like a salmon *Lady Ashtown*, and it looks as though it would hold up its head better.

Lady Mary Ward, from Messrs. McGredy and Son, is a real gem, of the type of *Duchess of Wellington*, but with a deeper orange tint.

Mrs. Fred Vanderbilt, also from the same raisers, is another fine bit of colour, reminding one of *Sunrise*, but in form more like *Countess of Gosford*.

A silver medal was awarded to **Moonlight**, one of the perpetual-flowering *moschata* Roses, which its raiser, the Rev. J. Pemberton, is giving us. They will be very beautiful garden varieties. It is like a pale *Trier*. Another one from the same raiser, named *Dinah*, is a pretty pink variety, and this gained a card of commendation. A similar award was given to *Coronation*, a very fine Hybrid Perpetual Rose, of superb form, and of a soft satin pink shade—this was from Messrs. Hugh Dickson; also to *Mrs. E. Alford*, which some thought deserved a higher honour. It is a fine big flower, in the way of *Mme. Abel Chatenay*, but larger. This was shown by Messrs. Lowe and Shawyer.

ROSE MRS. ANDREW CARNEGIE, AWARDED A GOLD MEDAL AT THE NATIONAL ROSE SOCIETY'S SHOW.

ROSES AS FREE BUSHES.

THE average reader of THE GARDEN cannot be aware that many of our best Roses may be grown as big bushes, or we should more frequently find them in gardens. Take, for instance, *Hugh Dickson*. How often do we find this grand Rose growing in a bed with such as *Caroline Testout* and *Mrs. John Laing*, totally usurping all the space by its long, straggling branches: but given a small bed to itself and its growths left long at pruning-time, we should have an abundance of its glorious crimson blooms to adorn our gardens. The same may be said of *Gustave Regis*. During a recent visit to Downside, Leatherhead, I saw a fine bed of this good Rose growing as big bushes nearly four feet high, and each bush a mass of bloom. *W. A. Richardson* is another Rose that may be so grown; and, indeed, many of the climbing *Teas* and *Noisettes* are a great success cultivated as free bushes. I have *Bouquet d'Or*, *Reine Marie Henriette*, *Zepherin Drouhin*, *Avoca*, *Sarah Bernhardt* and others growing as bushes some three feet to five feet high, and bushy as well, and they are a great success. *Lina Schmidt-Michel* is a beauty for this purpose; its huge semi-double flowers of *Mme. Abel Chatenay* colouring

Sunburst was not shown as large as it will come outdoors. The writer has had it of large size and superb form upon outdoor plants, and if it could have been put up in that form it would have gained a gold medal. It is a Rose that everyone must possess, and is one of the most lasting flowers I know of. I am certain it will prove to be one of *M. Pernet-Ducher's* best, and that is saying a good deal.

Mrs. Edith Part, from Messrs. McGredy and Son, is another remarkable colour, something of the tint of a highly-coloured *Beauté Inconstante* blended with *Lady Pirrie*. The colourings of the new Roses are so marvellous that it is only by comparing them in this way that one can describe them. The bloom is a nice solid flower, quite waxy in appearance.

are a joy to behold. I like to see some of these free-growing Roses in the centre of beds of bushes of the same colour, and I think it will soon be the recognised thing to plant the climbing sports of various Roses among the bush plants of the same variety; for instance, Climbing Lady Ashtown among bushes of the same, and also Climbing Liberty and Climbing Richmond. As a support three stout canes in the form of a tripod would be suitable, and one could plant three plants to each tripod. This arrangement would be a change from the use of standards as dot plants among bushes.

SPORTS OF ROSE KILLARNEY.

THIS good old Rose is behaving in a remarkable manner, for it is throwing off quite a number of

enlighten us as to its parentage, this might help us to solve the mystery. Anyway, the two recent sports should be obtained as soon as possible, because I should say they are going to be very useful. P.

ROSES AT KEW.

A FEW weeks ago we published an illustrated article on the Rose Dell at Kew, calling attention to the Ayrshire, multiflora and other Roses, many of which are now passing over. In this beautiful dell Roses are allowed to ramble almost at will over rustic logs and poles, and, needless to add, they flower in wild profusion. Helene, Tausendschön and Jersey Beauty have been wonderfully free-flowering this year. While the beauty of the Rose Dell has more or less departed for this season,

producing a quantity of exquisite flowers, while Lady Ashtown, Joseph Lowe and Mildred Grant are worthy of special mention as bedding varieties. A large bed of Clio is now a perfect mass of bluish pink flowers. With this variety, as with Frau Karl Druschki, which is also very fine, the long branches have been pegged down, and the side shoots from these maintain a quantity of bloom over a long period.

The pergola at Kew, of which we give an illustration, is aglow with colour, as it has been for some weeks past. Hiawatha and Lady Gay are remarkably good, and the trusses of bloom now hang down from the iron chains of the pergola in great profusion. Near to the Iris garden may be seen arches of Dorothy Perkins and its white variety, the two together making a most charming picture.

American Pillar and Dorothy Perkins are now at their best over the archways leading from the pergola to the herbaceous garden.

It would not be fitting to bring these notes to a conclusion without reference to the very effective display that has been created by planting rambling Roses near the water-side in the front of the Palm House. The varieties Dorothy Perkins and Lady Gay, now smothered with bloom, are drooping over the masonry, and the glory of the flowers is reflected in the placid water beneath.

A BED OF ROSE LA TOSCA AT KEW.

sports. Last year our American friends obtained a more double form, which they called the Double Pink Killarney. Now, the latest are a dark pink Killarney and a double white Killarney. Both of these are finding much favour on the other side of the Atlantic, one grower alone planting out under glass no fewer than 10,000 of each. The double white Killarney will, I think, interest us more over here, for it will be invaluable in a show-box with its exquisite form to add to its beauty.

It seems to one beyond question that the growing of Roses in huge quantities under artificial conditions tends to the sportiveness of a Rose. A case in point was the old variety Catherine Mernet, which has given The Bride, Bridesmaid and Muriel Grahame.

Would the propagating from cuttings have anything to do with creating these sports, or is it the artificial heat? Or is it explainable on Mendelian lines? In any case, it seems strange that several sports should follow in quick succession from Killarney, for the original variety has been in commerce now some fourteen years, and yet it is only lately it has taken to this sportiveness. If Messrs. A. Dickson and Sons would

there are numerous beds of standard and bush Roses, notably in the formal beds surrounding the Palm House, now to be seen in the height of perfection. That grand Rose Caroline Testout, which still retains its proud position as the best Rose for a town garden, is perhaps the best of all Roses at Kew at the present time. Grown in large beds, both as bush and standard, it is now rendering a really good account of its flowering propensities. La Tosca, a charming variety, is flowering in great profusion, as may be seen from the illustration on this page, and in a bed immediately opposite, the Lyon Rose is bearing a profusion of blooms; these, however, are a shade disappointing in tone of colour. There is also a good bed of the Lyon Rose in standard form, and another of Florence Pemberton, each with a carpet of Mignonette, which unquestionably enhances the beauty of the standard Roses. Grace Darling is not quite up to its usual good form, and La France, for some unknown reason, has apparently fallen into obscurity. Mme. Ravary, although not so prolific as some, is, nevertheless, very attractive on account of the beauty of its individual blooms. A bed of shapely bushes of Duchess of Wellington is now

if one like the bloom I have been obtained occasionally. It is semi-climbing in growth, which, perhaps, is another bad feature; but if planted out and the growths left long when pruning, it affords a glorious bit of colour, far surpassing Roses of the Maharajah type, and as a standard it is superb. I had not observed its fragrance before, but it is not unlike that of ripe Raspberries. P.

THE FRUIT GARDEN.

SOME GOOD STRAWBERRIES.

THE coloured cover of this issue represents some comparatively new and good varieties of Strawberries, and as the time for planting is now at hand, we commend these to the notice of our readers. The one at the top of the cover is Laxton's Cropper, a variety that was introduced by the firm whose name it bears in 1907. It is a midseason variety, the fruits being large and of excellent quality. They are also firm, and consequently travel well. On the left-hand side we have another fine Strawberry, named The Bedford. This, too, is a midseason variety, and was raised by crossing Dr.

Hogg and Sir Charles Napier, both good Strawberries. The Bedford possesses the fine flavour of Dr. Hogg and the good colour of Sir Charles Napier. It is a very robust-growing sort and a heavy cropper, and, as will be seen by the illustration, produces large and handsome fruits. The variety on the right is Laxton's Epicure, one of the best flavoured Strawberries ever raised. This is not to be wondered at when we know that British Queen and Fillbasket were its parents. Indeed, in flavour it is almost identical with British Queen, and its habit and cropping qualities similar to those of Fillbasket. Strawberries planted between now and the end of August will give good crops of fruit next year, provided the soil is well dug and manured, but the earlier they are got in the better.

THE FLOWER GARDEN.

THE SCOTCH ROCKET.

(HESPERIS MATRONALIS FLORE PLENO.)

THIS, one of our very choicest hardy plants, is in danger of dying out, as so few growers seem to know anything regarding its wants. To entirely lose this fine plant would be a calamity indeed, and every effort should be made

to increase the stock all over the country. I have known and cultivated these Rockets for many years, and find very little difficulty in keeping up a good stock. At the same time, disaster may overtake anyone if they neglect the plants for even one season. I have experimented for years with this plant, and while several plans are fairly satisfactory, I have proved over and over again that propagation by cuttings is by far the best method of raising a healthy stock.

How to Proceed.—As soon as the flowers fade, or earlier if they are wanted for room decoration, cut down the stalks to 3 inches or 4 inches from the ground. Loosen the soil all round the plants with a Dutch hoe, and if the weather is dry give an occasional soaking of water. Encourage fresh, sturdy growths by these and other means that may occur to the cultivator, for it is important to secure growths of fair size by the beginning of September. Of course, after one has obtained a fair stock, the best method for securing cuttings is to plant out a few of the strongest young plants in the reserve garden in spring, and as soon as the flower-stems rise cut them close back, and thus ensure plenty of early cuttings. As soon as the growths are large enough to make into cuttings, take them off with a knife, securing, if possible, a heel to each. Trim slightly in the usual way, and then insert in pots or boxes of light, sandy soil, taking care to keep the centres of the cuttings free of soil. Even the best of cuttings are usually rather short, so a good deal of care is necessary to secure them properly in the soil. I have heard of enthusiasts who tied each cutting to a small stake before inserting, as by this means the cuttings were kept steady until roots were formed. Personally, I have never tried this, but with very short cuttings I can appreciate the advantage of the method.

Treatment of Planted Cuttings.—Having inserted all the available cuttings, give a gentle watering and set in a cold frame. Keep close and shaded for ten days or so, and then gradually admit a little air, as the Rocket detests being coddled, and the leaves will most likely damp off if kept unduly close. The giving of abundance of air on every suitable occasion during late autumn, winter and spring, and a frequent removal of all dead foliage, are all that is necessary during that time. The removal of the dead leaves requires considerable care, as these do not readily leave the little plants, and if roughly handled the cuttings will be loosened, or even the tender roots destroyed at a later period. By the beginning of March the plants should be ready to be hardened off, and should then be planted out in fairly rich and well-tilled soil in a sunny situation. Soil of medium to heavy texture best suits this plant. I should perhaps have said that while boxes are suitable for the cuttings, I have always had the greatest success by using pots. A really good, strong cutting may be given a 3-inch pot, and smaller ones may be inserted round the edges of 4-inch or 5-inch pots, three to five in each. In February pot off singly those raised in boxes into 3-inch pots or round the edges of larger ones.

Other Methods.—In late seasons, or in extra dry summers, the growths made are frequently

the plants in autumn or spring, planting directly where they are to bloom, but this is by no means a safe plan. If the first two methods I have explained are carried out each season, one may always rely on having abundance of this fine plant to bloom during May and June. The true Scotch Rocket grows from 18 inches to 24 inches high, and must not be confounded with the tall French variety, although this also is quite worthy of a place in a large herbaceous border. It is by no means so difficult to manage, and may be broken up and replanted like the majority of hardy plants. The Scotch Rockets are nearly pure white, and have beautiful Stock-like, fragrant spikes of flower. There is also a fine lilac pink sort, almost as desirable as the white. The latter is slightly taller, but blooms at the same time.

Preston House, Linlithgow.

SWEET PEA NOTES.

The Great Show.—Although these notes will not appear in THE GARDEN for several days after the National Society has held its great annual exhibition, I am forced to write them many days in advance of the date. During the past few weeks I have had the pleasure of seeing a few thousands of plants in different places, and I have no hesitation in concluding that the present show will be

THE ROSE PERGOLA AT KEW, LOOKING FROM THE SOUTH END.

much too short for cuttings, so the plants should be carefully dug up early in September and divided with a sharp knife. Each crown with a few roots attached will make a plant if placed in a 3-inch pot; but if two or three crowns can be retained on each piece and given a 4-inch or 5-inch pot, far finer plants will be secured for next season's blooming. After potting place in a cold frame, and keep close and shaded for a few days. Subsequent treatment is identical with that already advised for cuttings. Still another way is to lift and divide

as good as any of its predecessors, and better than some of them. The flowers are of excellent size, substance and colour, and, artistically staged, will create a magnificent display, or they will do so unless hideous boards are down the middle of each stage, as I am led to believe was decided at a recent committee meeting. Our show has been the most beautiful of all, but such an addition will, I fear, completely spoil it.

Double Standards.—There is one thing that worries me considerably in regard to the show, and

that is the remarkable number of flowers which are throwing double standards. In the schedule for this year there is a rule under which double standards will disqualify any exhibit other than in three classes which are specified. This will involve the judges in the task of closely examining every bloom throughout each stand. This is by no means a light task, and there are some judges who will positively refuse to do it. And small blame to them. Disqualification must be done at times, as all experienced adjudicators know, but it is not a pleasant thing, and to inscribe the dread word on an exhibitor's card because he has one flower out of 300, or even more, in a stand is too terrible to contemplate. Personally, I am opposed to double standards, but that does not alter the fact that several hundreds of people appreciate them; neither does it the second fact, that a few blooms with double standards in a bunch make it conspicuously handsome. The trouble lies in that the double standard may not show itself, even to the most critical eye, until the exhibit is staged and the hall is cleared for the judges. Must the exhibitor be penalised for an error which he could not possibly prevent? Were he to put half the stems up with double standard flowers, the case would be altered, but the odd one is a dangerous thing, and will almost assuredly appear. I can remember the day when every exhibitor was disqualified in one of the most important classes at the "National" because two or three fiery individuals yearned to slaughter me. One of the disappointed ones had one spike too many in about two hundred and fifty. Would anyone suggest that that solitary spike was added to improve the group? Not a bit of it; but the rule said twenty, and no earthly body could make that either nineteen or twenty-one. Let us hope that there will be no such catastrophe with double standards. If there is, the society will require a new secretary, for Mr. Curtis will certainly be assassinated. The temper of the exhibitors at the "National" shows is not as sweet as it was in my day!

Club Judges.— In the dog world and the poultry world the "club judge" is an institution of the utmost importance, and I am of opinion that it would be an excellent thing if we could import the idea into the Sweet Pea world. It is clear from the awards made at some local shows that the impressions of some judges as to what constitutes a good Sweet Pea are weird, to put it mildly. The National Sweet Pea Society has now upwards of one hundred societies in affiliation, and for the benefit of these the desirability of drawing up a list of official judges cannot be questioned. The awards would then be made on a recognised approved basis in all parts of the country. One obstacle is that floricultural societies are not overburdened with cash, and they cannot always afford

to pay a competent man a fair wage for a fair day's work; but this I do not regard as insurmountable. It is not usually the fee which causes trouble, but the expenses, which rise to a respectable sum when one has to travel a few hundred miles and spend at least one night in an hotel. There are, however, scores of capable men in the country who could be retained at a reasonable fee, and who would not have to travel far.

HORACE J. WRIGHT.

SWEET PEA LADY MILLER.

Among Sweet Peas of recent introduction, this variety must take a foremost place. It is exceed-

SWEET PEA LADY MILLER.

ingly vigorous, flowers freely, and the blossoms are beautifully waved. It belongs to the cream pink section, the two colours being very delicately blended. Although there are now several good varieties in this colour section, all are very beautiful, and we cannot well have too many of them. When cut and bunched Lady Miller is particularly charming, and it is also very beautiful in the garden. If a census of Sweet Peas for colour were taken, we think those of cream and pink hues would be well on top. It was raised by Messrs. Dobbie and Co., and has been shown by them in very good condition this year.

THE KITCHEN GARDEN.

FRENCH SUGAR PEAS.

It is often remarked that we want more variety in vegetables, and this can be met by growing kinds that seem but little known. For instance, the French Sugar Peas are excellent when cooked whole, providing the pods are young and well grown. Last summer, being hot and dry, was very trying to the ordinary Pea crop in light soils, whereas the Sugar Pea was excellent. Of course, I would only advise its culture in a private garden, and even then only where variety or change of vegetables is desired, as it cannot be classed as a profitable vegetable. Being so little known or grown, it is not looked upon with great favour, yet it is an excellent summer vegetable in season from July to September. In poor land no lack of good food should be allowed at the roots. The soil must be deeply trenched and the plants given sufficient space to grow freely. The variety Mangetout may be classed as a medium grower. Last summer it did not attain a height of 3 feet, though in a wet season I have had it nearly 4 feet. W.

NEW VARIETIES OF ASPARAGUS.

Though most vegetables during the past quarter of a century have made wonderful strides, Asparagus has been almost stationary, so far as the introduction of new varieties is concerned. On the other hand, there has been great progress in its cultivation, and this is now more easy and profitable than it was some years ago. It may be well, however, to draw attention to a few new varieties. Objection may be made to this, as some may think it is desirable to grow the older sorts as well as possible, and in a certain sense I agree. On the other hand, I certainly think by the introduction of new blood we may get good results in the way of size, yield and earliness.

At the Royal Horticultural Society's Gardens at Wisley during last year some most interesting trials of Asparagus took place. But as all growers of this vegetable know, one, or even two, seasons'

trials will not be sufficient to prove conclusively any sorts as new or distinct. Although I believe the new varieties referred to were only two years old, there was a marked difference in the yield and size of growth over older sorts grown under similar conditions, so that there is great promise that the newer forms will prove superior and be valuable additions to a vegetable which almost everyone likes, and which is none too plentiful. For instance, an earlier variety will prove of great value, as when Asparagus comes in there is a scarcity of good vegetables. Some of the varieties under the name of Early Giant were greatly superior to the older sorts. G. WYTHES.

GARDENING FOR BEGINNERS.

THE LAYERING OF BORDER CARNATIONS.

THE border Carnations—that is, those which flower in the open ground during the summer months, are propagated by means of layers, and this is the time of the year in which to carry out the work. A few appliances are needed in order that the layering may be properly done, namely, a sharp, small-bladed knife, some pegs to secure the layers in their place, a small hand-fork to loosen the soil around the plants previous to layering, and a pad of some kind on which to kneel, for it is very necessary to come in close contact with Mother Earth. Carnation-pegs are sold for the purpose, but any piece of bent wire may be made to answer, besides which pegs may be cut from the stalks of Bracken or an old Birch broom. Long hairpins may also be used. Some good sandy soil passed through a sieve with a quarter-inch mesh is also required. This must be worked around the layer when it is fixed in position, and thus forms the medium into which the first roots are pushed.

How to do the Work.—All being ready, the actual layering may now commence. In the first place, the soil around the plant should be lightly forked up to a depth of a couple of inches or thereabouts; then take the shoot which is to form the layer, and with a downward pull remove any leaves from the lower part of the stem, as is shown in the accompanying illustration of a layered and rooted shoot. If the leaves are too firmly fixed, a sharp pair of scissors may be used. Then take the shoot in the left hand so that the bottom portion is uppermost, and support the stem with the forefinger. This will prevent any danger of the shoot snapping off when the cut is being made, and also enable the operator to regulate the extent to which the knife penetrates. It must be inserted about halfway through the stem immediately below a joint, and carried upwards to the next joint. If this is properly done and the shoot pegged down correctly, the separated portion of the stem assumes the character of a tongue or heel, and it is from this part that the roots are produced, as shown in the illustration. It is most essential that the cut remains open, otherwise the wound will heal without rooting, or do so only in an imperfect manner. Much might be written on the subject without conveying as clear an idea as a glance at the illustration. It is very important that the layered shoots are not too young and succulent, otherwise they are liable to snap, and much the same may happen if they are allowed to get too old and woody. Care should be taken not to crowd too many layers around a single plant, as it must be remembered that they will make more growth before they are fit to be separated from the parent, and consequently they will become weakened by crowding. Varieties of loose growth may have more layers put down than those with sturdy, compact shoots. When layering is completed, the soil should have a good watering through a fine rose in order to settle everything in its place, and

it is very essential that after this the soil is never allowed to get dry. Apart from this, an occasional overlooking to see that the layers are not loosened in any way, and also to keep free from weeds, are all that is needed till they are sufficiently rooted to be separated from the parent plant.

Treatment of Rooted Layers.—By the end of September the plants should be rooted sufficiently for them to be cut off, and then either planted into their permanent quarters or put into 4-inch pots, as in some districts they are frequently wintered in a cold frame. In cutting off the layers from the parent plant, a certain amount of care is very necessary. A sharp knife is required, and the buried portion of the stem should be cut by a downward thrust, as, if an upward cut is made, the stem is liable to break. Then with a trowel carefully lift the rooted layer, and shorten back the old stem

the advantage of a good top-dressing if applied to a lawn at once. The new soil will fill up all hollows and closely surround the roots of the grasses, and the latter will soon take possession of the additional loam and become stronger and more likely to pass through a severe winter safely. If closely examined, it will be clearly seen how bare of soil lawn grasses are at the present time.

The new compost should be of a gritty nature, and made moderately rich by adding some well-rotted manure. Pass all the ingredients through a three-quarter-inch mesh sieve and spread the mixture on evenly. Brush it to and fro, so as to gently work down the particles of soil, and then roll the lawn. So treated, the compost will not show on the surface, while at the same time it will be doing a vast amount of good to the lawn.

A CARNATION SHOOT THAT HAS BEEN PROPERLY LAYERED AND MADE ROOTS.

if it is too long. Whether planted in the open ground or potted, the young plants should have their roots exposed to the air for as short a time as possible, for the delicate fibres are very quickly injured. It is very necessary that the planting be firmly carried out, and, should the young plants be lifted by frost, it is most essential that they are again pressed into position as soon as it can be safely done.

H. P.

LAWNS AND DRY WEATHER.

ALTHOUGH many lawns have suffered a great deal owing to absence of rain and the excessive heat, it will surprise many persons when they see the rapid recovery some lawns will make. In numerous instances I find old, coarse grasses killed and others lessened in vigour considerably. No time should be lost now in raking off browned moss and faded coarse grass, and after the rake has been used to good purpose, follow with a half-worn path broom and brush up as much more as possible. Some crumbled soil will also be collected, but it is a very easy matter to replace it with fresh loam. This brings me to the main point in this note, namely,

pots, and, finally, to the flowering ones, those 7 inches in diameter. The same kind of compost must be used throughout, but finer in condition at the first than the two final pottings, viz., fibrous loam, two parts; leaf-soil, one part; rotted manure, one part; with sufficient coarse sand to render it all porous. To one bushel of the above combined parts add a 7-inch potful of old mortar-rubble. When the young plants are 6 inches high, pinch off the tops and thus cause side shoots to grow. A few plants may be left at this, as they will flower early; but others should be pinched twice. Then they will be later in flowering and so form a succession.

If a frame is available, the plants should be grown in it up to the time the flower-buds show prominently. Directly the plants are well rooted in their flowering pots, commence to feed them judiciously; later, weak doses of manure-water and artificial manures may be given; but at first clear soot-water is the best, and if applied at every second watering, both the colour of the flowers and the foliage will be improved. Some of the double whites and pinks are most useful for cutting and placing in vases.

SHAMROCK.

GARDENING OF THE WEEK.

FOR SOUTHERN GARDENS.

The Flower Garden.

Border Carnations.—From the middle to the latter end of July is a very suitable time for layering the growths of these for providing next year's flowering plants and the plants to get thoroughly established. Before commencing to layer some fine soil should be got in readiness, and some pegs for holding the shoots firm. A compost of loam and leaf-mould, with a liberal addition of coarse sand, is preferable, though, failing that, old potting compost passed through a fine sieve will do.

Liliums.—Attend to the staking and tying of these as they extend, using neat stakes, nothing being better than Bamboos. The stronger-growing species will, of course, need stouter stakes in proportion. Where such as *L. auratum* and varieties are planted among Rhododendrons and the like, they will be greatly benefited by copious supplies of water and applications of liquid manure-water.

Montbretias.—The growths must be kept looped up or supported with twiggy branches, and where grown in lines the Dutch hoe should be worked frequently among them. On light soils a mulch will be of much value, but on heavier soil, and where the ground was well enriched and deeply worked, it is not so essential.

The Rock Garden.

The Dripping Weather we experienced during last month has caused a great many plants to make unusual growth, and many of the commoner subjects have exceeded their boundary. When overhauling for weeds and making tidy, any such subjects, if encroaching upon better plants, should be curtailed, and, if necessary, be taken up altogether.

Campanulas.—For flowering on the rock garden during July many of the dwarf Harebells are excellent and remarkably free, and are soon established where the soil is well drained. *C. pusilla* when massed together is a pleasing sight, as is also, at the time of writing, *C. G. F. Wilson*.

Helichrysum arenarium.—One of the most interesting plants now flowering, and remaining so for a considerable length of time, is this alpine Everlasting. It is of free growth in almost any position, but seems to delight in plenty of sun, when the stems holding the heads of yellow rustling flowers are more freely produced.

Plants Under Glass.

Mignonette.—With a little care and attention, more particularly to watering than anything else, it is quite easy to have pots of this fragrant flower in the winter months, and nothing is more delightful for the decoration of the greenhouse. Seed may be sown now, and another batch or two at intervals of a fortnight or a month. Sow a pinch of seed singly into small pots, and have the latter cleaned, drained, and filled with a nice sweet compost of loam, leaf-mould and coarse grit or sand. Stand in a frame and admit air freely, especially when the seed has germinated, and as soon as the seedlings are large enough, thin out to the best. The plants must be grown sturdily throughout, and potted as becomes necessary.

Solanum Wendlandii.—Among greenhouse climbers this is one of the showiest, especially when the young growths with their flowers are allowed to hang down. For this reason the tying in should not be too severe. Give copious supplies of water to the roots, and occasional waterings with liquid manure-water.

Cyclamen.—A frame with a north aspect will suit the plants admirably now for the time until they are housed. Give abundance of air, removing the lights whenever possible, and in warm localities the lights may be drawn off on mild nights. To encourage growth, syringing must be regularly practised and the growth kept free from thrip, and occasionally rearrange the plants, rake over the ashes and give a dusting of soot.

The Kitchen Garden.

Winter Greens.—Up till the end of the month the later plants of the various Kales, Savoys and Broccoli may be planted. Well water in, and if the weather is dry, water previous plantings.

Turnips.—Make good sowings of Turnips where vacant ground can be found for autumn and winter crops. Thin out earlier sowings at intervals.

Keep the hoe working among them, and dust with soot in the early morning when the weather is showery. For the present sowings select a somewhat shaded position.

Late Peas.—These will greatly benefit by dampings overhead on mild evenings and a mulch of manure or long litter applied to the surface of the soil. If the weather is dry, water copiously, as drought is conducive to attacks of mildew, which will play havoc with the crop. If the ground is hard, the surface should be lightly loosened on either side of the rows before watering.

Fruits Under Glass.

Melons.—The plants in heated frames that are swelling their fruits must not be allowed to suffer for the want of water, and, to encourage the fruits to swell freely, varying stimulants should be afforded. The fruits should be elevated from the soil so that they do not become disfigured by insect pests, and the foliage kept well syringed to keep it in a healthy and clean condition. The lights may be well elevated during the hottest parts of the day, closing in the afternoon, according to the weather. Remove lateral growth so that it does not become too congested, and have a slight circulation of heat in the water-pipes at night. For the latest crop in the house sow seed at once, if this has not already been attended to, and raise quickly in the usual manner.

Figs.—These make a quantity of growth at this season, and thinning is necessary, or overcrowding will result. Where the trees are cropping freely, and especially in restricted borders, watering and feeding must be done liberally and a heavy mulch afforded the borders. Thoroughly syringe the foliage to keep it in a healthy condition and free from spider. At this season of the year little fire-heat is wanted, and during hot days abundance of air may be afforded the trees. A little shading stippled on the glass will be beneficial.

E. BECKETT, V.M.H.

Aldenham House Gardens, Elstree, Herts.

FOR NORTHERN GARDENS.

The Flower Garden.

Watering.—A few days of heat at this period causes some plants to suffer for the want of water, *Astilbes Davidii* and *grandis*, *Rudbeckia speciosa*, *Lobelia cardinalis* and *Phloxes* being peculiarly susceptible to drought. One should not wait for the plants to show distress, but give liberal douchings before that. I always add manure to the water, which carries the plants longer than pure water, and it has the further advantage of adding lustre to the colour of the flowers. Hard water is not to be recommended.

Herbaceous Borders.—Shorten the stems of *Rudbeckia laciniata* varieties grouped without stakes. Flowered-out single-stemmed plants of *Aconitum Napellus* may be rooted out to give others more space. *Helianthus* growing too close should be thinned. Perennial Poppies, such as *Papaver rupifragum* and *pilosum* will need much attention, cutting out the old stems so as to encourage the new to fill up. *Anchusa italica* varieties need much the same treatment when they flower to the end of the season.

Gladiolus.—Short stakes should be placed to these before the spikes lengthen out. This enables them to maintain an upright position without having to use longer and ugly stakes later. They much appreciate manurial dressings and a fair supply of moisture in dry weather, but continued wet and cold are hurtful and lead to disease in the corms.

Shrubs.

Hedge-Trimming.—Where there is much of this work to overtake, a commencement may be made, choosing dull weather for the operation. A hedge should invariably be cut with a slight taper, which keeps it from sagging, and, if not overdone, cannot be noticed.

Box Edgings.—Those in old-fashioned flower gardens with gravel walks between the heds may also be cut at this time. The edgings are most in character when cut square-topped, with upright edges so as to appear like dwarf hedges. The very slightest inclination of the sides towards the upper edges should also be made in these.

Philadelphus.—The varieties derived from *P. microphyllus*, such as *Lemoinei erectus*, will now be out of flower, and need the old flowering shoots to be cut back somewhat to give space for the young ones. Pruning, moreover, stiffens the shoots, which in this and some other sections, e.g., the late-flowering *grandiflorus*, are apt to become very straggly if allowed to grow unchecked. The young growths strike root as freely as *Verbenas* when taken at this time of year and the cuttings dibbled in sand or Cocoonat fibre waste in a propagating-pit. *P. roseiflorus* and *P. purpureo-maculatus* are perhaps the two finest varieties.

Fruit-Houses.

Tomatoes.—These usually make more foliage than is of utility, and besides the side axillary growths, which must be rigidly suppressed, a portion of the leaves may also be removed with advantage and the others shortened. While in full growth the plants ask for abundance of water at the root with regular supplies of manure, but with a dry, airy atmosphere. In some structures it is essential to shade the plants on very hot days, else the foliage gets browned and curled up.

Cucumbers.—These can be kept in a healthy and free-bearing condition for a long time by means of judicious pinching, light cropping, removal of damaged foliage, and surface-dressings of rough turf and manure; but it is now worth while to sow seeds or strike cuttings in order to have a young stock to replace any that may give way next month when the nights get cold.

Grape Vines.—Lady Downe's will now be forward enough to be liable to scorching in tightly-glazed houses. Besides airing freely, late and early, a very slight shade over all the roof is advantageous. Muscats at this season are also liable to scorch, and the same means must be adopted. If the temperature should run too low at some hours, the pipes must be heated, but usually this is not essential provided time can be given for the fruit to ripen.

The Vegetable Garden.

Jerusalem Artichokes.—It does no harm to the crop to stop the stems, which saves them from being blown about by the gales which we experience sooner or later. A little soil thrown up the stems by means of a spade also helps to steady them.

Leeks.—These are now growing rapidly, and it will be necessary to determine whether the ridges may be levelled down or left for a few weeks longer. Those started in January will need fairly constant attention to tying up with thick brown paper, and watering with a weak solution of liquid manure poured through drain-tiles terminating near their roots.

Parsley.—Early-raised plants set out at wide intervals will now be well forward. There is a danger of coarsening the foliage if manure is applied; but should the plants show by the colour of the leafage that manure is needed, apply a slight dressing of soot, and hoe it into the surface of the ground. It is not too late to sow seeds for a spring crop, which sometimes comes in useful after a severe winter.

The Plant-Houses.

Roman Hyacinths.—As soon as the bulbs come to hand, put up some for early flowering. Six-inch pots are suitable, and the bulbs may be arranged so as to nearly touch each other. Those at 20s. per hundred are to be preferred to cheap ones, which produce only one spike and sometimes none, an average of four from first-quality bulbs being usual. Water and place in a frame, covering with some material that will keep moist.

Narcissi.—Home-grown bulbs lifted a few weeks ago may now be potted or boxed, the soil well moistened, and the whole stood in a sheltered and shady position. A very slight covering of cinder-ashes is sufficient for these. Good varieties are *Golden Spur*, *Victoria*, *Telamonius plenus* and *Glory of Leiden* for early flowering; and for later, *Emperor*, *Sir Watkin*, *Horsfieldii*, *Mme. Plomp*, *Sulphur Phoenix* and *ornatus*. Hyacinths and Tulips should be ordered without further delay. The earliest Hyacinths are *General Pelissier*, *Mme. van der Hoop* and *Charles Dickens*; and of Tulips, setting aside *van Thols* in variety, *Proserpine* (perhaps the best of all), *Thomas Moore* and *Crimson King*.

R. P. BROTHERSTON.

Tynninghame, Prestonkirk, N.B.

SOCIETIES.

NATIONAL SWEET PEA SOCIETY.

JULY 9 AND 10.

THE twelfth exhibition of this popular flower was held in the Royal Horticultural Hall, Westminster, on the above-named dates, and obviously was a signal success. This was so from every point of view, though more particularly, perhaps, from the spectacular standpoint, and because of the added beauty to such an exhibition during recent years of many entirely new or greatly-improved shades of colour. This greater diversity of colour is in reality a great gain not to exhibitions only, but to the garden and, in turn, to decoration. Hence the scene, the product of a solitary type of flower, was as remarkable as it was good. The interest taken in the exhibition and the flower may best be gauged from the fact that competitors to the number of 180 came from all parts of the British Isles. Particulars of the show are appended. The general arrangements were admirable.

SUTTON CUP CLASS.

In this class, for twenty-one bunches of Sweet Peas, distinct, to be selected from the varieties recommended by the floral committee in the Classification List, the first prize was won by A. W. Stirling, Esq., Holme Lea, Goring, Oxon, whose splendid lot contained Thomas Stevenson, Gladys Burt, J. Ingman, Nubian, Sunproof Crimson, Tennant Spencer, Evelyn Hemus, Mrs. Harcastle Sykes, Earl Spencer, Flora Norton Spencer, Florence Nightingale (fine lavender), Elsie Herbert, Paradise Ivory and America Spencer. Second, C. Hopton, Esq., The Cottage, Greenford, with a collection of much less fine flowers. Three of the finest collections in this class were disqualified owing to the presence of double standards, which were distinctly forbidden by the conditions. There were seven competitors, some groups being very fine.

For twenty-four bunches of Sweet Peas, distinct, the first prize went to Mrs. A. E. Kensington, Haversbrack, Uckfield, whose best vases were Mrs. W. J. Unwin, Scarlet Emperor, Clara Curtis, Mrs. Harcastle Sykes, Barbara, Nettie Jenkins, Red Chief, Helen Grosvenor, Elsie Herbert, Flora Norton Spencer and Senator. Second, A. W. Stirling, Esq., Holme Lea, Goring, Oxon. Some of the finer exhibits in this class also were disqualified because of the presence of double standards.

HENRY ECKFORD MEMORIAL CLASS.

In this class, for twelve bunches of Sweet Peas, distinct, named varieties in commerce, the first prize was won by E. G. Moccatta, Esq., Woburn Place, Addlestone (gardener, Mr. Thomas Stevenson), whose grand lot comprised Melba, Hercules, Edrom Beauty, Queen Mary, Thomas Stevenson, J. Ingman, Queen of Norway, Elfrida Pearson, Mrs. C. W. Breamore, R. F. Felton, Elsie Herbert and Marjorie Linzee. A magnificent lot of particularly bright flowers, that were, however, subsequently disqualified, owing to the presence of a double standard. The cup then went to Sir Randolph Baker, Bart., M.P., Ranston, Blandford (gardener, Mr. A. B. Usher). Barbara, Lavender George Herbert, Evelyn Hemus, King Manoel and Doris Usher were of exceptional merit in a group of much excellence.

Six bunches of new Sweet Peas, distinct, selected from varieties first put into commerce since the autumn of 1911. First, Mr. Edward Cowdy, Longhall, County Armagh. Dobbie's Cream, King Manoel, R. F. Felton and Mrs. Cuthbertson were the best.

Three bunches of pink or cream pink Sweet Peas, waved, distinct: The first prize was awarded to F. Chetwynd Stapleton, Esq., Englefield Lodge, Englefield Green, whose vases were of the varieties Mrs. R. Hallam, Miss Chetwynd Stapleton and Mary Langdown. Three charming varieties. Second, R. P. Brooks, Esq., Rosehill, Par Station, Cornwall. Mrs. Hugh Dickson and Hercules were the best. Third, Sir Randolph Baker, Bart. There were eleven competitors in this class also.

For three bunches of Sweet Peas, distinct, with double standards, Mrs. A. E. Kensington, Uckfield, was first with Audrey Crier, Scarlet Emperor and Orange Perfection; second, Sir Randolph Baker, Bart., who had Dobbie's Cream and Mrs. Breamore as his best; third, Dr. J. E. Phillips, Malpas. There were seven competitors in this class, the quality being very fine.

OPEN TO ALL—CLASSIFICATION CLASS.

Collection of twenty-four varieties of Sweet Peas (not more than one variety of any colour given in the Classification List may be shown): The first prize went to Mr. J. Stevenson, Poole Road, Wimborne, whose vases of Princess Victoria, Earl Spencer, Florence Nightingale and Thomas Stevenson were very fine; second, Mr. H. D. Tigwell, Harrow View, Greenford. There were four exhibitors, the class being a most effective one.

For twelve bunches of Sweet Peas, distinct, the first prize went to Mr. F. G. Bealing, Burgess Street Nurseries, Bassett; second, C. B. Gabriel, Esq., Horsell, Surrey; third, E. Otter, Esq., Stanhope Park, Greenford. In each instance the class cards bore this legend: "As all exhibits in this class contain double standards, the judges recommend" the prizes as above.

Three bunches of seedling Sweet Peas, distinct, to consist of varieties not yet in commerce (the exhibitor must be the raiser of the varieties, and each to be named): First, Mr. R. Bolton, Carnforth, who had Andrew Aitken (salmon), Agriola (blush lilac and mauve) and Birdbrook (maroon, waved fancy); second, A. W. Stirling, Esq., Holme Lea, Goring, Oxon, who had Cissie (mauve), Mrs.

A. W. Stirling (cerise) and Hotty (lilac blush); third, Mr. Robert Wright, Halsall Lane Nursery, Formby.

E. W. KING CHALLENGE CUP.

For twelve bunches of waved Sweet Peas, distinct, the first prize went to Alfred F. Blades, Esq., Rookfields, Reigate, with splendid vases of Melba, Hercules, Edrom Beauty, Othello Spencer and Flora Norton Spencer; second, R. P. Brooks, Esq., Rosehill, Par Station, Cornwall. This class was well contested.

Six bunches of Sweet Peas, distinct: First prize, R. P. Brooks, Esq., Par Station, Cornwall, whose best were Doris Burt (scarlet), Mrs. W. King (cerise), Isobel Malcolm (cream) and Dazzler; second, Sir Randolph Baker, Bart.; third, Mr. Thomas Jones, Ruabon.

Six bunches, distinct, double standards: First, Mr. F. G. Bealing, Bassett. Bertrand Deal, Duplex Spencer, Clara Curtis, Sunproof Crimson and Elfrida Pearson were included. Only one entry.

Three bunches of Sweet Peas, distinct, Helen Pierce type, waved or grandiflora varieties: First, Mr. H. H. Lees, Warlington, Havant; second, Messrs. Faulkner and Aitkins, Barrow Road Nurseries, Tarvin, near Chester; third, Mr. T. Cross, Bury St. Edmunds.

BURPEE CUP CLASS.

A display of waved Sweet Peas, to be arranged on a space 8 feet by 3 feet, and not to exceed 4 feet in height: First, Mr. A. E. Alsen, Denmead, Waterlooville, for an admirable lot; second, F. A. Wellesley, Esq., J.P. Woking; third, Mr. C. W. Breamore, Winchester. All the exhibits in this class were disqualified under the double-standard clause, the prizes being recommended as above. There were eight splendid tables arranged, the whole constituting a great attraction in the centre of the hall.

DISTRICT CLASSES.—LONDON COUNTY CLASSES.

Six bunches of Sweet Peas, distinct, at least two to consist of varieties first put into commerce during or since the autumn of 1911. The only exhibitor was disqualified for showing mixed bunches.

SCOTTISH CLASS.

Six bunches (conditions same as last): First, Mrs. Dunbar of Dunbar, Seapark, Forres, N.B. Only two exhibitors, one being disqualified for double standards.

IRISH CLASS.

Nine bunches of Sweet Peas, distinct (under similar conditions): First, Mr. Edward Cowdy, Longhall, County Armagh, who had excellent examples of White Queen, Mrs. R. Hallam and Tennant Spencer; second, Mrs. James Hall, County Tyrone.

WELSH CLASS.

Under similar conditions: First prize, Mr. J. E. Alan Gibbs, Dinas Powis, Glamorgan, Nancy Perkin and R. F. Felton being good; second, Mr. Thomas Jones, Bryn Penylan, Ruabon.

NORTHERN COUNTIES CLASS.

Under similar conditions: First, Dr. J. E. Phillips-Malpas, Cheshire, Clara Curtis, Flora Norton Spencer and Queen of Norway being good; second, Mr. J. F. Harrison, Ulverston.

WESTERN COUNTIES CLASS.

There was only one entry in this class, the first being given to R. P. Brooks, Esq., Rosehill, Par Station, Cornwall. The prize in this class was a "recommended" only, a double standard being found in the exhibit.

EASTERN COUNTIES CLASS.

First, F. E. Hall, Esq., Redbourn, Edna Unwin, Mrs. Hesington, Hercules, Dobbie's Cream and Flora Norton Spencer were all grand. Second, Sir M. Turner, Bedford, Romford. Thomas Stevenson, Elsie Herbert, Nubian, and Sunproof Crimson were excellent. There were twelve competitors.

MIDLAND COUNTIES CLASS.

First, Mr. Robert Hallam, Radcliffe-on-Trent, who had Clara Curtis, Nettie Jenkins and Hercules in splendid form. Only two entries.

SOUTHERN COUNTIES CLASS.

First, E. G. Moccatta, Esq., Woburn Place, Addlestone (gardener, Mr. Thomas Stevenson), who staged a grand lot of flowers. His best vases were Barbara, Mrs. Routzahn, Lady E. Eyre, Money-maker, Marjorie Linzee, and Mrs. C. W. Breamore, Scarlet Emperor being particularly fine. Second, Sir Randolph Baker, Bart., M.P., Blandford; third, A. L. F. Cook, Esq., Iver, Bucks.

BREAMORE CHALLENGE CLASS.

Twelve bunches, distinct, named varieties in commerce: First, Mr. Edward Cowdy, Greenhall, County Armagh, who had a really grand lot. Wenroe Castle (bronze and blue), Barbara, Mrs. R. Hallam, White Queen, Gladys Burt and Lavender Queen were all superb. There were only two exhibitors, the second prize going to Marshall Y. Green, Esq., Eynsford.

Six bunches, distinct: First, Mr. W. H. Smith, 12, George Street, Hailsham, Sussex. Sunproof Crimson, Masterpiece, Hercules, Freda, President and Aurora constituted this fine lot. Second, Mr. J. A. Newman, Elm Grove Road, Weybridge, who had a splendid set, Nettie Jenkins, Helen Lewis and Thomas Stevenson were all good. Third, H. St. J. Cavell, Esq., Cheam.

The Hawmark Challenge Cup class, for twelve bunches, was keenly contested, and was won by Mr. T. Jones, Ruabon, who had splendid quality bunches of Sunproof Crimson, Lavender George Herbert, Elsie Herbert, Hercules and Queen of Norway. The second-prize stand could not be found; while Mr. J. Hall, Moy, County Tyrone, was placed third.

For six bunches Mr. W. H. Smith, 12, George Street, Hailsham, won first prize with effective examples of White Queen, Hercules, Mrs. De-lington, Sunproof Crimson and Majestic. It was followed by Dr. G. S. Leggatt, Thompson Road, Harpenden, having Melba, Hercules, Sunproof Crimson and Countess Spencer as his best examples; while Mr. A. Everett, Fairview, Chappel, Essex, was third.

For three bunches there was a host of entries, Mr. W. H. Smith winning with A. Unwin, Queen Victoria Spencer and John Ingman; and Mr. M. P. Cressey, Oak Manor, Tonbridge, third.

There was a rare tussle for the Horace Wright Challenge Cup. This was, however, secured by Mr. W. H. Holloway, Percyville, Port Hill Gardens, Shrewsbury, who staged splendidly, some of his best being Thomas Stevenson, William Bolton, Mrs. C. W. Breamore, Mrs. Charles Foster, Elfrida Pearson, Queen of Norway and Barbara. The second prize fell to Mr. F. Green, The Beeches, Swaythling, Southampton, who had capital vases of Melba, Doris Usher, Lady Eyre and Hercules; while Mr. C. R. Jaggs, Hertford Heath, was a fine third.

The Walter Voss Challenge Cup, for six varieties, was won by Mr. E. J. Gee, Broadway, Chesham, with a good, level display. Mr. H. Hesford, Addlestone, followed; and Mr. G. Pain, 64, Linzee Road, Hornsey, brought up the rear.

For six vases of waved varieties Mr. E. D. Marshall, Early Rise Arms, Reading, was awarded first prize with fine specimens of Nubian, John Ingman, Maud Holmes, Constance Oliver and Tennant Spencer. Mr. C. R. Jaggs was second; and Mr. W. T. James, Kempton Hoo, Bedford, third.

For three bunches Mr. E. D. Marshall led off with Mrs. H. Sykes, Thomas Stevenson and Stark's Queen; followed by Mr. W. Mousley, Fairholme Road, Ashford; while Mr. G. H. Guy, Reigate, brought up the rear.

For two bunches of cream pink varieties Mr. W. Mousley won first with excellent examples of Constance Oliver and Doris Usher; while Messrs. E. N. Sears and F. Green secured the other prizes in the order named.

DECORATIONS.

Mrs. F. G. Bealing, Bassett, won first prize for an epergne, using a combination of blue and cream with suitable foliage; second, Mrs. A. Duff, High Street, Charnbrook; third, Miss J. G. Cuthbertson, Mark's Tey.

The first prize for a vase went to Mrs. W. Maslin, Orchard Hill Cottage, Addlestone, for a tasteful arrangement. Mrs. A. R. Bide, Farnham, was second, and Mrs. F. G. Bealing third.

There were fourteen entries for a dinner-table decoration. Mrs. W. Puleher, jun., 21, Moulsham Street, Chelmsford, won first prize; second, Mrs. A. Duff, High Street, Charnbrook; third, Mrs. A. Everett, Chappel, Essex.

There were twelve entries for two button-holes and one spray, the first prize going to Miss J. G. Cuthbertson; second, Miss Kitty Ackers, Huntley Manor, Gloucester; third, Miss B. E. Armstrong, Fish Pond Road, Hitchin.

AWARDS.

Awards of Merit.—To R. F. Felton, a very fine lavender waved variety, the flowers nicely placed on the stems, from Mr. R. Bolton; to Aricole, a pale lavender edged with a deeper shade of the same colour, very fine flowers, from Mr. R. Bolton; to Decorator, a rich rosy cerise, flowers large, with fine waved petals, from Messrs. G. Stark and Son; to Bertrand Deal, a fine rosy lilac form with well-placed flowers, from Mr. Bertrand Deal; and to Lady Miller, a cream variety suffused rosy pink of a pleasing shade, from Mr. I. Malcolm.

NON-COMPETITIVE EXHIBITS.

The trade groups were arranged right round the wall of the hall, each exhibitor having the same space. Many of them made the most of it by ascending 10 feet or more high. Messrs. J. King and Sons, Coggeshall and Reading, presented a tasteful exhibit, having a large arch in front covered with fine varieties. Some of the best sorts were Gladys Burt, Hercules, Evelyn Hemus and Edward Prince of Wales.

Messrs. Dobbie and Co., Edinburgh and Mark's Tey, had some splendid Sweet Peas arranged beautifully between trails of Smilax and Asparagus. The most prominent varieties were Melba, Decorator, Inspector, Lady Miller, Thomas Stevenson (very fine), Lavender George Herbert and Mrs. H. Dickson.

Messrs. S. Bide and Son, Limited, Farnham, presented a telling exhibit, which included Waved Prince Olaf, R. F. Felton, Jeannie Gordon Spencer, Barbara, St. George and Florence Nightingale.

Mr. W. O. Cantley, Bury St. Edmunds, had a pleasing exhibit, consisting of three tall columns with vases displayed round them. Melba, Prince George, Hercules and Charles Foster were good here.

From Messrs. Aldersey and Marsden Jones came an effective stand, though it could not be said that the blue drapery improved it. Their chief varieties were Romani Ranni, Tortoiseshell, Moonstone, Sycera Lee and Beryl.

Messrs. Barr and Sons, Covent Garden, had a fine exhibit in which were noted such varieties as Barbara, R. F. Felton, Nubian, Scarlet Monarch, Thomas Stevenson and Mrs. J. C. House.

Messrs. W. Voss and Co., Millwall, also had a fine decorative exhibit, with Edith Taylor, Barbara, Rosabelle and Mrs. W. J. Unwin as some of the best features.

Messrs. G. Stark and Son, Great Ryburgh, had a good display of fine-quality Peas, especially the varieties The Lady, Decorator, Maggie Stark, Helen Williams and Primrose Beauty.

The exhibit of Robert Sydenham, Limited, Birmingham, was nicely displayed in rustic arrangements. Their

EDITORIAL NOTICES.

Every department of horticulture is represented in **THE GARDEN**, and the Editor invites readers to send in questions relating to matters upon which they wish expert advice.

The Editor welcomes photographs, articles and notes, but he will not be responsible for their safe return. All reasonable care, however, will be taken, and where stamps are enclosed, he will endeavour to return non-accepted contributions.

As regards photographs, if payment be desired, the Editor asks that the price required for reproduction be plainly stated. It must be distinctly understood that only the actual photographer or owner of the copyright will be treated with.

*The Editor will not be responsible for the return of artistic or literary contributions which he may not be able to use, and the receipt of a proof must not be taken as evidence that an article is accepted. Publication in **THE GARDEN** will alone be recognised as acceptance.*

Offices: 20, Tavistock Street, Covent Garden, W.C.

NOTES OF THE WEEK.

Roses in Saughton Park, Edinburgh.—The Saughton Hall Park, Edinburgh, continues to develop in value and in beauty under the management of Mr. M'Hattie, the Edinburgh City gardener, and among the interesting and beautiful features are the old gardens of the Saughton Hall Mansion included in the park. The Rose garden is now very fine, and a number of members of the Town Council and other friends visited the park on the invitation of Councillor Inches, convener of the Parks Committee, on July 12. They were very much pleased with what they saw, and the Rose garden in particular was greatly appreciated. Various improvements tending to the comfort of the public are in contemplation.

Show of Forced Spring Bulbs.—A special exhibition of forced spring bulbs will be held on Tuesday and Wednesday, March 4 and 5, 1913, by the Royal Horticultural Society, the object being to demonstrate the varieties best suited to gentle forcing. Exhibits of small and large collections are invited from amateurs and the trade. Royal Horticultural Society medals will be awarded according to merit. The Council also offer (subject to the general rules of the society) a number of prizes presented to them by the General Bulb Growers' Society of Haarlem for various exhibits of Hyacinths, Tulips and Daffodils. Full particulars of these can be obtained from the secretary of the Royal Horticultural Society, Vincent Square, Westminster.

Silver Trophy for Amateurs' Rock Gardens.—On Wednesday, May 14, 1913, the Council of the Royal Horticultural Society will offer a silver trophy, presented to them by Mr. Clarence Elliott of Stevenage, for an exhibit of alpine and other plants suitable for a rock garden. These are to be arranged with rockwork as a rock garden in a space 6 feet by 3 feet. There must not be less than eighteen or more than twenty-four species or varieties. The first prize will be the Clarence Elliott Trophy. The Council will award a suitable medal according to merit, at their discretion, to the exhibitor adjudged second, and possibly also to the third. It is pleasing to note that at last the Council have realised the folly of holding a show the day after a Bank Holiday, and are holding the show referred to above on the Wednesday instead of the Tuesday following Whit-Monday.

Rose Lady Godiva as a Weeping Standard.—Surely this is the loveliest of all Roses grown in this form. What a cool, refreshing colour it is, one of the daintiest of blush pinks; and having this variety we want neither Christian Curle nor Dorothy Dennison. Weeping Roses are bound to be largely planted. There is nothing so beautiful as a well-developed weeping standard of the

wichuraiana Roses, and there is now variety enough for the most exacting. Up to the present Shower of Gold has been very disappointing in this form. The buds seem to live, but fail to unite to the Briar. There is still room for a really good yellow that keeps its colour well when fully out. Gardenia is fine, and probably Klondyke will be good. Aviateur Blériot is a glorious orange colour in the bud, but pales on opening. One of the best of the orange section is Desiré Bergera, a real gem, and one deserving of very extensive planting. It is a deeper-coloured form of Leontine Gervaise, one of our most fragrant ramblers as well as one of the loveliest colours.

Kent Commercial Fruit Show.—The second Kent Commercial Fruit Show will be held at the Corn Exchange, Maidstone, on October 29 and 30. The number of classes has been increased and several important alterations made. All the classes for six boxes of a variety have been opened to Great Britain and Ireland; by this it is hoped that numerous exhibits will be sent from the other fruit-growing districts, and that their methods of packing and grading will be represented. Other new features include classes for Apples Worcester Pearmain and Lord Derby, and also one for Pears, Messrs. Coupe and Sons, Covent Garden, London, have very kindly presented a challenge cup, value 20 guineas, for the best exhibit of six boxes in classes for Bramley's Seedling, Newton Wonder, Lane's Prince Albert, Blenheim Orange and Worcester Pearmain coming from Kent, Surrey or Sussex. The hon. secretary is Mr. R. Wellington, The College, Wye, Kent, from whom full particulars can be obtained.

The Spanish Broom.—A great deal is to be said in favour of the extended cultivation of Spartium junceum, the yellow-flowered Spanish Broom, for it continues in bloom for a considerable period from the beginning of July, and never fails to bloom profusely. As a rule, it is met with from 5 feet to 8 feet in height, but its height and habit depend almost entirely upon the will of the cultivator. Some people prefer to see freely-grown plants, and such may be obtained with a diameter of 5 feet or 6 feet. Others prefer to see their plants more compact in habit, hence the practice of cutting them severely back to near the base of the previous year's growth each spring, which encourages a rather stiff, globular habit, the plants at flowering-time being perfect globes of gold. In whichever way the plant is to be grown eventually, it is necessary to be rather severe with the pruning-knife in the early stages, otherwise the plants become very leggy. For the wild garden or for planting on dry, sandy banks, the Spanish Broom is excellent, for it does not require anything in the way of rich soil or elaborate cultivation. Seeds may be sown in pots, and the young plants must be kept in pots until planted in permanent places.

CORRESPONDENCE.

(The Editor is not responsible for the opinions expressed by correspondents.)

The "Breaking" of English Iris.—In my note on this subject which appeared on page 362 of last week's issue, the Iris under question was referred to as *I. Niphium*. This should have been *I. xiphioides*.—J. JACOB.

Curious Laburnums.—There is an interesting half-column of reading under the above title in the issue for June 22 of THE GARDEN. As the Editor mentions there are some examples of *L. Adamii* at Syon House, may I also record having seen this plant at two other places? One was at Fonthill House Gardens, Tisbury, Wilts; the other in a small garden at Fortis Green, East Finchley, N. Both were well-grown trees of the usual Laburnum size.

Rose Marquise de Sinety.—Like "Avon," I, too, would add a word in praise of this lovely Rose, most particularly because of its unique colour. True, it has not yet proved very free in flowering with us, but this may be remedied with age. Its growth is reasonably strong, with glossy bronze green foliage, while the flower passes, as it opens, from yellow to a bronzy shade, as "Avon" has it, "a much-needed colour in the Rose world."—C. T., *Highgate*.

Dwarf Double Crimson Sweet William.—Two years ago I found a large plant of this in an old garden, and from the cuttings taken from it I have now a most effective border to two long Rose-beds. This Sweet William is quite dwarf; the foliage makes a cushion of green, and the rich double crimson flowers only grow 5 inches or 6 inches high. It lasts a long time in flower, and should make a most useful plant for the rockery or for edging beds or borders. I would be glad to know if it is uncommon?—(Mrs.) F. E. LLOYD, *Croghan House, County Roscommon*.

Roses Excelsa and Crimson Rambler.—As these two Roses flower almost at the same time, one is tempted to refrain from adding the first-named, as, of course, Crimson Rambler is established in nearly every garden. But while I wish to be fair to our old friend, I must say there is no comparison as to its usefulness. While we have perhaps a little more brilliant colouring in Crimson Rambler, it is minus the elegant growth and beautiful foliage of Excelsa. It is one of the best of our crimson weepers—certainly a great rival to Hiawatha and Delight; and while I think even Excelsa may be eclipsed by Mr. Turner's Coronation, I have yet to prove it outdoors. I have Excelsa, which has made quite a small arbour in two years. It is a very rapid grower, and pays well for being spread out as much as possible.—P.

Exhibiting Daffodils.—Mr. Jacob certainly has put in another "word"; he owns it is a hard word, and I had to refer to the dictionary to find a meaning. "Mix" is clear enough, but "mycetic." Well, all I can find is "mycetes," which means "a genus of American monkeys, commonly called 'the howlers' from the loud sounds of their voices." so I take it to mean a sort of mixture of howling monkeys. Oh! Mr. Jacob, how can you use such expressions when talking about our lovely Daffodils! Really, I am quite shocked. But seriously, to try to follow Mr. Jacob's meaning: he says that the show flower and the garden flower are two distinct things, to be treated differently and to be thought of differently; that we are muddling things up, that there are flowers which are right either way,

the lucky dogs (monkeys, surely), these "mixomyctic" flowers, which he says are neither fish, flesh, fowl nor good red herring. Really, my poor brain begins to whirl. But to return to the point. What we want, as Mr. Jacob says, is a National Daffodil Society, but it must be "National" in the true sense of the word and exist to encourage the sort of flower that is wanted by the public, and not be a kind of mutual admiration society of so-called true florists. I myself sincerely hope the Daffodil will never enter the select circle of the "florists' flowers." I am delighted to hear that experience has taught "A Small Exhibitor" that faking is safe to be penalised in competitive classes. I take off my hat to those judges.—W. A. WATTS. [Myxomyctes is a genus of slime fungi that were at one time classed as animals, but are now regarded as plants. The slime fungus that causes finger-and-toe disease of cabbages belongs to the family.—ED.]

Privet Flowering Freely.—I have never seen Privet so well flowered as it is this year. The variety *angustifolium* has very large heads of blossom where the plants have been allowed to grow uncut for several years past. Of course, the wood was exceptionally well ripened last year, which accounts for the exceptional freedom of flowering this year. On some of the railway banks near Bournemouth, the Privet bushes—many of them large ones—are white with blossom. In other parts of this neighbourhood the *Enonymus* is also flowering well.—G. G.

Sweet Cherries.—These are fine, large, and of good flavour this year. When well protected by fine-meshed netting they can be kept for a long time, and if the sun is extra powerful, a thin shading of canvas or tiffany should also be used in order to prolong the season. I have kept them for the Scottish season in this manner. Among some of the best are Bigarreau de Schrecken, Bigarreau Napoleon, Early Rivers, Frogmore Early Bigarreau, Governor Wood, Geant de Hedelfinger and Black Eagle. For kitchen use May Duke and Morello are two of the best.—W. A. COOK, *Leonardslee Gardens*.

Erigeron Asa Gray.—Under this name there is being cultivated a very distinct *Erigeron*, about whose origin one would like to know more, as it seems, for the present, to be wrapped in obscurity. If one dared venture upon a conjecture, it is that it may be a hybrid of *Erigeron aurantiacus*. It is not to be confounded with the plant sold as *E. salsuginosus* of Asa Gray, which is quite a different thing. The one under notice grows almost a foot high in ordinary soils, and has flowers hardly the size of those of *E. glaucus*, but of a real biscuit colour and with an orange centre. The description of the colour may not appear attractive, but the plant is quite a pleasing one, especially when it has attained some size.—S. ARNOTT.

Rustic Trellises as Wind-breaks.—Very recently a gentleman pointed out to me some Peas growing at the edge of a cliff 100 feet high. The only protection the Peas and other crops received was afforded by a rustic trellis about five feet high. At times the gales were very strong, but the Peas and other crops were quite undamaged and looked very well indeed. Not far away, however, a wall was built as a protection for garden crops against the strong winds from the sea, but the crops were badly damaged through the wind sweeping over the top of the wall in a cold current. The rough trellis in the first-named garden broke the force

of the wind, and there was no concentrated current blowing directly on the plants. I remember, some years ago, a hedge of *Laurustinus* forming the boundary fence above a low stone wall of a garden near the sea. There the gales were exceptionally strong at times, and the plants suffered considerably. A gentleman recommended the owner to fix wire-netting of half-inch mesh about two feet away from the bushes or hedge. This was done, and in about two years' time the *Laurustinus* had regained their normal good health, were growing freely and producing plentifully nice, young shoots. Unless one sees the good results, one can scarcely believe that such protection will be as beneficial as it is.—B.

The Double Standard in the Sweet Pea.—In view of the editorial remarks appended to my note on page 362 of last week's issue, I would like to add another word. Our esteemed Editor remarks that the National Sweet Pea Committee "recognised that the double standard had come to stay, and provided three classes for it, but rigidly, and we think rightly, excluded it from the other classes." If, however, the society recognised that the "double standard had come to stay," its present action is a little strange, since what it excludes to-day it must perforce, in such circumstances, admit to-morrow. Curiously, too—and very curiously—in those classes where, according to schedule, the double standard was admissible, no adequate response was made; in one class, if my memory serves me aright, none at all; hence it would appear that the double standard was not so plentiful as it appeared from the disqualifications. One finds no fault with the National Sweet Pea Society for formulating a rule or specific condition and adhering to it. In view, however, of all the circumstances at the recent show, one might reasonably ask, Why did not the society adhere to its emphatically laid down rule as to the double standard to the bitter end? But it did not do so. For example, in the Sutton Cup Class the defaulters were all promptly disqualified, the result being that some comparatively inferior exhibits, but which conformed to the schedule, obtained prizes. That is quite a usual method of procedure where disqualification has taken place. Now, in Class 8, one of the classification set, and in the Burpee Cup Class, the whole host of competitors were disqualified owing to the presence of double standards, yet the judges immediately appended a card to the class card of the finer exhibits recommending these the prizes—in short, advising the committee to abrogate the rule applying to the double standard. Was it too much to expect that the committee should have sternly refused to follow such advice in the face of conditions so emphatically and prominently set forth, and to have said "No; we will award no prizes at all in these classes"? I suppose so, judging from the fact that the prizes were awarded on merit, and that, after all, the rule counted for naught. The above are good examples of "Guilty, with a strong recommendation to mercy"; but there was no mercy vouchsafed to the solitary exhibitor in the London County Class, who was disqualified outright, yet he had as much right to consideration as the rest, for his was no greater sin. To the minor lights in the Sweet Pea exhibition world it must be a little consoling to know that more than one of the National Sweet Pea Society's committee came to grief over the double standard clause, and of such one might of a surety say, "They have digged a pit, and have fallen into the midst of it themselves."—E. H. JENKINS.

Clematis montana.—The huge and beautiful specimen of the above plant shown in the photograph finds its home at The Gables, View Road, Highgate, N. As may be judged from the picture, it was a magnificent sight. It is the finest show the plant has ever made. Probably the thorough ripening of the wood by last year's brilliant sunshine may account for such a wealth of blossom. It is about thirty feet to thirty-five feet in height.—C. T.

Rose Conrad F. Meyer.—On page 338, issue July 6, "An Essex Reader" has a good word for this Rose. Your correspondent does not over-estimate the good qualities of the variety in question, as it is undoubtedly a very fine one. In a garden in a town on the South Coast I recently saw a very fine specimen trained to the trunk of a large Fir tree. The plant was flowering profusely the last week in June, and gave promise of doing so for many days more. The partial shade cast by the large tree seemed to suit the Rose very well, the flowers being very rich in colour.—AVON.

The Jungle Fungus.—A gentleman recently pointed out to a number of gardeners a border in his garden where he had failed to grow several Chestnut trees. Eventually he had the soil removed to a considerable depth and some distance around, and this revealed a lot of fungus, of which a culture was obtained, and it proved to be the jungle fungus (*Rosenaria necatrix*). The position was at the edge of a wood, and the fungus was traced for a considerable distance. After removing all that could be found, the soil was limed, a hole was again made, left open to the sun for three days, then coated with lime, and a plant put in. So far the specimen is doing well. This case, however, proves that there is a real danger from fungus where choice trees are grown, and that, before they are planted, it is advisable on the part of the cultivator to make sure that the soil is quite free from it.

Wistarias.—The fine illustration of the splendid *Wistaria* which appeared on page 355, issue July 13, reminds me of a collection of these plants at Clandon Park, Guildford, the country seat of the Earl of Onslow. In the centre of a sunk garden on the lawn some very tall, strong posts had been fixed to form an octagon, I believe, with a still taller central post. Chains connected all these posts, and some of the best varieties of *Wistarias* had been planted near each one when I saw these gardens a few years ago. When the whole of the structure is covered with branches and the flowers are fully developed, the effect will be most beautiful, though somewhat formal. The informal growth of the specimen shown in THE GARDEN adds very considerably to its beautiful appearance. It reminds me of a *Honeysuckle*

which I saw in a wood near the New Forest some time ago. The plant almost covered every branch of an Oak tree and depended gracefully from them, and, being well flowered, looked charming. Both Oak and *Honeysuckle* were in good condition. Near by another *Honeysuckle* had covered the trunk of a Pine tree to a height of about sixty feet.—G. G.

FORTHCOMING EVENTS.

July 30.—Royal Horticultural Society's Exhibition at Vincent Square. Lecture at 3 p.m. by Mr. Hooper on "The Pollination of Fruit Blossoms."

THE GREENHOUSE.

MIGNONETTE IN POTS.

HOW TO GROW PLANTS THROUGH THE WINTER.

THIS fragrant flower is greatly appreciated at all times when grown in the open borders, but it is especially liked when grown in flower-pots in the greenhouse or conservatory. Pot plants are usually had in flower during the spring months when blossoms are scarce. To obtain very strong plants, seeds must be sown

in July, and the resultant young plants grown on very steadily during the autumn and winter months. As wireworms are great enemies of *Mignonette*, the cultivator must be sure that the soil is quite free from them. Old fibrous loam is the best; use two parts of such, one part of leaf-soil, and one part of sand, rotted manure and old mortar rubble.

It is very important that the compost be sweet, and on this account I do not believe in sowing the seeds in their flowering pots, because the soil in bulk has to remain in the pots so long, and it often turns sour. Sow the seeds in pots $3\frac{1}{2}$ inches in diameter, dropping four or five seeds half an inch apart on the surface of the soil in each pot. The same kind of compost must be used both at the time of sowing the seeds and at the repotting later on, only when the latter work is done the compost should be in a rougher condition. Cover the seeds with fine soil, and place the pots in a cold frame with the lights well tilted above them. It is better to do this than to allow the plants to get saturated with rain-water occasionally. Gradually thin out the young plants to one in each pot. I have duly noted the condition of plants as grown in pots under similar treatment. Three, two and one *Mignonette* plant were, respectively, grown in pots, and all were very fine indeed, but the single plant made the best "pot." It was a superb specimen, branching out freely, and bearing long and well-formed spikes of blossoms. The point of the plant must be pinched out either when the specimen is quite young, so that the new side shoots may get strong before the dull days of winter come, or the plant must not be pinched before the first week in January. Late autumn stopping results in the growth of weakly side shoots. Place the plants in $6\frac{1}{2}$ -inch pots in September, and remove them to a shelf in a greenhouse or conservatory in October or, at the latest, early in November. When there are plenty of roots in the large pots and the longer days come, feed the plants judiciously. They require plenty of light and air in fine weather. *Machet*, *Victoria*, *Spiral*, *Perfection*, *Bismarck* and *Golden Queen* are all beautiful varieties to grow. B.

THE KITCHEN GARDEN.

SEASONABLE NOTES ON VEGETABLES.

OUTDOOR TOMATOES.—Half a century ago Tomatoes were scarcely known in our gardens, while now it is the exception rather than the rule to find a place in which they are not represented either indoors or outdoors, and commonly they are in both. The cottager and the amateur regard them as necessaries in the same way as they do Potatoes and Cabbages, though they cannot, of course, and would not if they could, allocate as much space to them. At the present time they are in excellent condition, and are making constant demands upon the time and attention of the grower. Water is required in abundance, and it is almost invariably wise to supplement it with weak liquid manure. The particular kind that is used is not of material importance, provided that a change of diet is arranged and it is never overdone. It is of paramount importance that all shoots springing in the axils of the leaves shall be rubbed out, and that no defoliation shall be done beyond what is absolutely necessary to admit light to the fruit.

Winter Greens.—The planting of Brussels Sprouts, Broccoli, Savoys and Kales must be continued as land falls vacant. With the single exception of Broccoli the plants demand a deep, thoroughly-cultivated soil that is in excellent heart, and no efforts must be spared to meet these requirements. Broccoli, however, that has to stand the winter is preferably planted on a firm base, and the soil should be made solid about the roots to encourage a sturdy, hardy growth. In rich, open ground the plants grow too rapidly, and become so soft that they succumb to the variable weather. A grubbed Strawberry-bed or a site that has carried a crop of autumn Onions is suitable, all weeds being removed, and planting done with a bar. The roots of occasional plants ought to be closely examined in case of an attack of gall weevil; if the knobs are seen, pinch or cut them off and draw the roots through a thick puddle of soot, lime and soil.

Sowing Lettuces.—It is the admirable rule in most gardens to sow Lettuces at frequent intervals, the quantities usually being rather small in preference to sowing big batches at protracted intervals, because splendid quality is thus practically assured. Now we shall soon have to be thinking about autumn and winter produce, and the site selected ought to be prepared ready for sowing immediately the most favourable time comes. A variety of the Hicks' Hardy White type should be chosen in the Cos section, and of the Stanstead Park group in the Cabbage section, as these stand splendidly and the quality from well-grown plants is first class.

Early Potatoes.—These were good and early this season, and most of them are now out of the ground. It is wise to remember that they do not store well; that is to say, they soon lose quality when they are lifted. The rule, then, should be to dig in small quantities for immediate use, as one thus secures the finest flavour. If tubers for seed next season are to be saved at home, only the best must be chosen for the purpose. This does not mean large ones; on the contrary, sets weighing about three ounces are the most serviceable, but they must be perfect in shape, according to the variety, and there must not, of course, be the slightest sign of disease. Varieties

CARPENTERIA CALIFORNICA, A SHRUB FOR A WARM POSITION.

which follow the earliest must be dug in succession, as they will still add considerably to their bulk if the weather is favourable and disease does not appear. Watch closely for it, and apply Bordeaux mixture the instant the first trace is discovered.

Peas and Beans.—To keep the Peas and Beans going now will demand incessant attention, especially on light soils. Watering at the roots and the application of liquid manure now and again are excellent, but the soil for a foot from the plants at least on each side of the rows must be kept open by frequent stirring or hoeing, or, what is better, have a thick mulching of manure. An evening hosing now and again will still prove decidedly beneficial.

H. J.

TREES AND SHRUBS.

A BEAUTIFUL FLOWERING SHRUB.

(CARPENTERIA CALIFORNICA.)

A NATIVE of the Sierra Nevada, California, this evergreen shrub, though hardy in most parts of the country, will be found to thrive and flower more satisfactorily when planted against a sunny south or west wall or some other similar position. The flowers are produced, three or four together, in clusters at the ends of the shoots; they are white and fragrant, about two inches or rather more across, with an attractive cluster of yellow stamens in the centre. The leaves are 3 inches to 4 inches long, broadly lanceolate, glossy green above, much lighter beneath. *Carpenteria californica* belongs to the Natural Order Saxifragaceæ, is figured in the *Botanical Magazine*, t. 6911, and has been in cultivation in this country rather more than thirty years. Fairly free in growth in light, sandy loam, with, for preference, a little peat and leaf-mould added, the subject of this note forms a pleasing evergreen bush of good size.

A. O.

THE INDIAN HORSE CHESTNUT.

(ÆSCULUS INDICA.)

THOUGH first introduced into this country from Northern India more than sixty years ago, *Æsculus indica* has found little favour with planters. This is, presumably, because the tree is not quite so hardy as the majority of the Chestnut family. The behaviour of the tree, however, where it has been planted leads one to the conclusion that there is every hope of success, except in cold and bleak positions. The largest specimens are in Suffolk, two trees at Barton in that county being between sixty feet and seventy feet in height. There are several vigorous young trees at Kew, the tallest, which flowers annually and ripens seeds, being about twenty feet in height. In Northern India *Æsculus indica* is found growing at an elevation of 8,000 feet to 10,000 feet. Perhaps its greatest claim to recognition is the fact that it flowers towards the end of June in a normal season, when the majority of the Horse Chestnuts have finished flowering.

There is a richness about the appearance of the Indian Horse Chestnut—the luxuriant, shining green foliage and the dainty colouring of the flowers—which readily distinguishes it from the other species. The leaflets are five to seven on a leaf, occasionally nine, the largest, generally the middle one, being sometimes a foot in length. The flowers are white, borne in a fairly closely arranged raceme; the two small upper petals are heavily blotched with yellow when opening, changing with age to orange red; the lower petals are tinged with pink.

THE FLOWER GARDEN.

FOXGLOVES FOR WOODLAND AND PLEASURE GROUNDS.

THE Foxglove (*Digitalis purpurea*) is such an easy plant to grow, and a fairly frequent inhabitant of our hedgerows and woods, that too often very little attention is given to it in gardens. By years of careful selection we now possess a strain of Foxgloves in every way—colour, size of flower and height—vastly superior to the wild plant. The white flowers, often prettily spotted, form a pleasing contrast to the varying shades of pink, rose and rosy red. A pleasing advance of recent years is the yellow Foxglove, obtained by crossing *Digitalis purpurea alba* with presumably *D. ambigua*. The flowers may be described as buff or rich cream. One of the best strains of the yellow Foxglove is that catalogued by Messrs. Sutton as Giant Primrose. The careful selection and harvesting of seeds is so thoroughly done by seedsmen that even seeds of Foxgloves are offered in separate colours, a very large percentage of which come true.

The would-be grower can, if he wishes, purchase, instead of a packet of mixed seeds, white, rose or spotted varieties separately. A curious break or freak is that variously known as *monstrosa* or *gloxinaeflora*. In this plant, instead of the spike of flowers all being semi-pendent, the top or terminal one is upright in shape, like an inverted bell, and several times larger than the usual Foxglove flowers.

While there are very few places in a garden where the Foxglove will not grow in shade or sun, there are certain places in the pleasure grounds and woodland for which it is admirably adapted. The naturalising of Foxgloves in moist, open breaks in the woodland, made by cutting down trees or clearing away shrubs, is now undertaken in many places. A few plants thrusting up their heads in the shrubby borders, where space permits, between the shrubs, or a large group in the pleasure grounds, as is well shown in the illustration, deserves consideration. And what of the Foxglove for the small garden! It is one of the best plants for the shady north border, where so few plants are satisfactory, and it is often seen to advantage in odd corners, where the seeds may fall and come up with no attention among hardy Ferns.

There is very little more to be said about the cultivation of the Foxglove. To flower the following season the seeds should be sown from March to May; but when allowed to fall and come up unaided, the seeds are not ripe until July or August. Falling at this time the plants are not large enough to flower the following year; self-sown seeds thus are generally approaching two years old before flowering. Though spoken of as a biennial, the flowering Foxgloves often develop another growth from the base, which blossoms the succeeding year. As will be seen from the accompanying illustration, it is a free-flowering plant when properly treated.

A. O.

SWEET PEA TRIALS AT SUTTON GREEN.

FAVOURED with perfect weather, the National Sweet Pea Society held its outing to the Sutton Green (Guildford) trials on Thursday, July 11. The party was a representative one, and included two growers from California, who, conscious of their own failure with the Sweet Pea seed crop this year, viewed the very promising rows of Sweet Peas at Guildford with a certain amount of envy. It was generally agreed that the Sweet Peas had never before looked so well at Sutton Green, and Mr. Harry Foster, the trial superintendent, is to be complimented upon the success of this year's trials.

The all-pervading Sweet Pea disease, however, has made its presence felt, and this was particularly noticeable among the cream-coloured varieties.

New Varieties.—There is no new variety of outstanding merit, and no first-class certificates

in fours, sent by Mr. R. Bolton; and Bertram Deal, deep lavender, with a strong inclination to throw double standards, sent by Mr. William Deal. With such a multiplicity of varieties as seen at the trials, it is difficult to keep pace with them, and while there were many good novelties at Sutton Green, the following were, in our opinion, remarkably good: Constance Hinton, the largest white, but just spoilt by a pink tint in some flowers; Corene, a true variety of salmon shade; Stirling Stent, a fine salmon variety which improves with age, the flowers being remarkably fine, even without shading; Thomas Stevenson, a first-rate orange scarlet variety, good from all sources from which it was sent for trial; Red Star, a grand scarlet; Royal Scarlet, also good, but not quite fixed; Scarlet Emperor, which in our opinion is the best of all the scarlets; Edith Taylor, salmon rose, one of the best of Mr. Holmes' raising; and Spencer Blue, synonymous with Southcote

FOXGLOVES CLUSTERED IN A WOODLAND GLADE.

have been awarded this year. Nevertheless, there are a few novelties worthy of special mention, and these, no doubt, will become favourites when better known. Honours had been awarded to new varieties a day or so previous to the outing, and no fault was found with the awards made. Two varieties given awards of merit are held in reserve for the silver medal. They are R. F. Felton, a lovely mauve, and Lady Miller, a beautiful salmon, with a faint tint of bronze in the standard. It is a variety of great promise for table decoration, and will also be telling in the hands of the exhibitor. Both of the varieties are apparently true, and both are sent by that successful raiser, Mr. A. Malcolm. Other varieties to obtain awards of merit are King White, a very handsome white variety, from Messrs. A. Dickson and Sons; Decorator, a very fine variety sent from three different growers, one of whom describes it as rose pink, another as crushed strawberry, while the cautious third has not ventured upon a description at all; Agricola, soft lavender with a faint flush of pink, and producing its flowers

Blue, quite true and of lovely colour. The outing to the society's northern trials at the Burbage Experimental Station, near Hinckley, took place on the day following. A duplication of the Sutton Green trials is held at Burbage, where Major C. C. Hurst, F.L.S., is the trial superintendent. The awards to new varieties are based upon the results of both trials.

SWEET PEA JOTTINGS.

Growing Under Glass.—One of the minor things that struck me at the International Show was the marked difference between the same variety when grown under glass and when out in the open. There were a couple of sorts for comparison on Messrs. E. W. King and Co.'s stand. I do not think I ever quite realised as I did then what a contrast there is between the results of the two, and how a covering of glass somehow puts a touch of beauty and refinement in the colouring that is wanting without it. It is to the Sweet Pea as the

glove is to the lady's hand. [Query—Ed.] Since I came home it so happens I have seen the same thing in my own garden. My pot plants are much later than usual this year, as I did not sow until the very end of February, and some of them have hung on flowering until I had the same varieties out of doors. It was miserable, damp weather all the ten days when they were first opening, and they had the greenish edge and pinched look about the standards, so that the comparison was still more in favour of those under the glass roof. My practical suggestion is that it is well worth while anyone who has the necessary head-room of 7 feet or 8 feet in a cool, and afterwards, when May comes in, in a cold, greenhouse having a dozen pots of Sweet Peas to just forestall the open-air ones. There is a minimum of trouble while growing, and the lengthening of the season and the exquisite delicacy of the blooms well repay what little there is.

Scent.—I shake my head sadly over some of the defects of the much-vaunted monstrosities that nowadays do duty for flowers. I remember when I was in Mogador, many years ago, my Jewish interpreter telling me that his young fellow country-men when they were choosing a girl for a wife always liked "plenty of her," and that a slim, refined-looking one had nothing like such a good chance. Such was their taste. Is it not the same with Sweet Pea lovers in the present year of King George V.? They like "plenty of her" in the flower they affect, and that is all. Such a thing as scent is hardly taken any notice of in the awards of to-day. What have our noses done to merit such treatment? They never have all the opportunities of enjoyment that their friends "the eyes" have. Is it not a bit hard to take some of that little away? I pleased my old nose hugely this year. It has since told me it was the greatest Sweet Pea treat it had had for ages, and it has put it down as one of its yearly requirements. This is the "memo.": Buy a packet or two of Mother-o'-Pearl—*extra* sweet-scented, an old-fashioned silvery grey flower; the sweetest Sweet Pea.

The Doctor's Sweet Peas.—I saw Dr. Phillips' Sweet Peas about a fortnight ago. They all looked the picture of robust health, and I felt sure he would have a good season. Since then I see they have done well at Hanley and in London. But what I really wanted to say was that I was especially charmed with Queen of Norway, Rose Diamond and Doris Usher. They are three lovely shades for house decoration. A word, too, for our well-tried friend Clara Curtis. As grown at Malpas it was grand. It is very beautiful in vases with some nice, fresh green foliage of its own. I say to myself, Suppose that it was the buttercup yellow

we are expecting, would it be as pleasing? Would it be as uncommon? We have so many strong yellow flowers and comparatively few pale primrose. But, then, everyone of us is a fearful novelty-hunter at heart.

JOSEPH JACOB.

[We fully endorse Mr. Jacob's remarks about the desirability of retaining the fragrance and refinement of Sweet Peas. A Sweet Pea without fragrance is not worthy of the name, and we hope the National Sweet Pea Society will not encourage such flowers.—Ed.]

SEASONABLE NOTES ON AURICULAS.

Alpine Varieties.—Several weeks ago I ventured to give the names of a few alpine Auriculas which

Teviotdale, Ullswater and Mildred Jay are all excellent. Admiration is very pretty, if good, but the centre is sometimes weak, and I do not like it so well as I did in former years. Dazzle is wonderfully bright in colour, but has a nasty trick of burning in the body colour just outside the centre. There are more yellow-centred sorts than white and cream, but the prettiest, to my mind, are Claude Halers, Duke of York, Dean Hole (small, but very bright), Ettrick, Firefly, Flora McIvor, Marie Corelli (late in flowering, handsome), Mrs. Markham, Perfection, Rosy Morn, The Bride and Uranie." I am delighted to commend this excellent selection, many of which I have, and can therefore personally commend. If other readers will favour with their pet selections, I shall be pleased to embody them in this column from time to time as opportunity permits; but my notes have to be written some time in advance of publication, so those sending must not be disappointed if they do not see their lists in the issue of THE GARDEN published the same week as they have posted their letter.

Sun and Shade.—Auriculas have a decided partiality for sun just as they have for shade. Their special preference is for sun in the morning and evening, and shade during the hottest part of the day. It is therefore necessary so to arrange the frame or the house devoted to them that these requirements are met, as it means so much to the maintained excellence of health and satisfactory progress. It is essential, too, that the atmosphere of the structure shall be kept sweet and cool by ample ventilation; stagnation will lead to trouble and worry with these plants quicker than almost anything else, as far as my experience teaches me. With a view to encouraging admirable growth, the soil must be moist; to make it sodden will lead to the rotting of many of the most valuable roots, while to allow it to become as dry as dust will mean that roots will shrivel up. The happy medium is the thing for which to strive.

Show Varieties in Borders.—Although the show Auriculas are equally as hardy as the alpine varieties, they are not usually grown in the open garden, because the exquisite colours are so extremely liable to be marred by the weather, much more so, in fact, than the alpine flowers. I should not grow the choicest varieties of either section out of doors all the year round, as many would almost certainly perish in the winter months. Those who have plants upon which they set real store, and which they are therefore anxious to keep for flowering next season, will be well advised to lift and pot them. The operation will not demand much trouble, and the time will wholly depend upon the number to be handled. Precisely as in ordinary

RODGERSIA PINNATA, A HANDSOME PLANT FOR ROCK GARDEN OR BORDER.

(See page 379.)

were favourites of mine and grew well with me, but the selection was not sufficiently modern to please one or two of my readers. Now, Mr. J. L. Gibson most kindly sends me an up-to-date list, and this I gladly give here, thanking him on my own behalf, as well as on that of the many readers of THE GARDEN, for the trouble and care that he has taken in the matter. Mr. Gibson says: "I am very pleased to send a list of alpine Auriculas as requested. The varieties are not selected because of their exhibition virtues, but for their beauty, size of pip and truss, and generally for the great pleasure they will give their cultivators. Among white and cream centred varieties, Bluebell, Argus, Janet, Miss Berkeley, Mrs. Douglas, Phyllis Douglas,

repotting, pots that are deep in proportion to their diameter ought to be given the preference, and the soil may advantageously be practically all sound fibrous loam. If the clumps are large, they must be divided according to judgment or necessity. When the work is finished, put them in the greenhouse or frame, and see that the utmost care is exercised in watering, especially during the first two or three weeks—until, in fact, they have become perfectly accustomed to the changed conditions. F. R.

THE ROCK AND WATER GARDEN.

A BOLD PLANT FOR THE ROCK GARDEN.

(RODGERSIA PINNATA.)

UNTIL within recent years *Rodgersia* was regarded as a monotypic genus, and, indeed, but one species, *R. podophylla*, was seen or known in cultivation. Now, however, thanks mainly, if not entirely, to the unceasing enterprise of Messrs. James Veitch and Sons, several new and important species and varieties have been added, each and all alike valuable to the garden, where, whether in flower or in the fulness of their leaf beauty, they are without a rival.

Regarded generally, the species are reputedly of a moisture-loving nature, though there are exceptions, and certainly the finest solitary example known to the writer was a specimen clump, about six feet across, in an open border in the sun-kissed garden of the late Rev. H. Ewbank at Ryde many years ago. Not only did the plant grow and thrive in ordinary loamy soil, but also put on late in the summer the fine rich leaf colouring that rendered a plant of such distinction a feature in the garden. At other times one or other of the more recently-introduced kinds are seen in grand condition in full sun where a never-failing water supply is within reach of the root-fibres. For preference, however, I should prefer a generous mixture of loam, peat and leaf-soil in about equal parts, with an addition of one-fifth well-decayed manure, plenty of root moisture and a sunny position, as well as one sheltered from north and east.

The plant in the body of the picture is the more recently-introduced *R. pinnata*, whose flowers are of salmony pink tone, and of which no description is required in the circumstances. There is also a pure white variety of this plant, which is highly desirable.

R. æsculifolia has large, erect panicles of pinky white, fragrant flowers, and handsome bronzy green leaves after the style of the Horse Chestnut; hence the specific name. Another remarkable species is *R. tabuliformis*; this is characterised by large peltate leaves and inflorescences of creamy white flowers. All are natives of Japan or Western China, and perfectly hardy in this country. E. H. JENKINS.

THE ROSE GARDEN.

ROSES WITH BAD HABITS.

PERHAPS it is natural for raisers when sending out a new Rose to extol all its good points and to be very blind to its faults. Shakespeare says if we all had our deserts, who would escape a whipping? and perhaps some fault could be found in every Rose grown. Now, I do not propose to make this a complete list, because I would invite the views to be given by some of the readers of THE GARDEN. Neither do I propose to specially condemn a Rose because it is scentless, although in the opinion of many, myself included, this is a very bad fault or defect which should make one hesitate before they plant it. I think I cannot do better than commence with a Rose that usually takes the highest position as a show bloom, and that is

Bessie Brown. I am constantly hearing complaints against this Rose, and it is generally that

Avoca, beautiful at times, but woefully thin, and it has also a tendency to turn blue. In like manner

His Majesty is very much over-praised. Now and then one obtains a fine flower, but in an amateur's garden it would be a very poor thing, and not a patch upon some of the good old Hybrid Perpetuals like *Comte de Rainbaud*.

Konigin Carola is perhaps one of the best of pink Roses, its blooms being of huge size and the petals very handsome, but the split centre of nearly every bloom spoils it very much indeed, so much so that one can rarely obtain a bloom for show.

J. B. Clark.—One great fault of this Rose is that it grows so strongly, and one is troubled to know what to do with it. The best method of culture is to treat it as a free bush; but how can the small amateur do this? I would suggest planting it against a fence or use it as a pillar Rose. Then

Killarney, what a beauty she is, but how sadly prone to mildew, so much so that the plants are

A BEAUTIFUL BED OF ROSE JOSEPH LOWE.

it fails to open well and its head hangs down as if the Rose were ashamed of its own loveliness. I know exhibitors do not object to this fault, because they maintain that it helps to keep the bloom clean; but give me a Rose that is held holdly upward, displaying its beauty to all who pass by.

Souvenir de Pierre Notting and **Mme. Constant Soupert** are two lovely gems; but who can recommend them to the novice, for scarcely a bloom is produced devoid of a blemish generally upon the outer petals? In my opinion it spoils the beauty of these two Roses so much that I cannot recommend them to anyone, except to those who exhibit.

Betty is, to me, exceedingly uninteresting apart from the bud, except perhaps in a very cool season or in autumn. Now, if this Rose had the power to hold its open blooms as do *G. Nabonnand* and *Peace*, it would be a fine thing. But the flowers are far too thin and fleeting for the amateur whose space is limited. Then there is

often a sheet of white. Of course, this can be checked by the use of *Cyllin Soft Soap*, if applied in good time; but one could wish it were mildew-proof like *A. R. Goodwin*. P.

(To be continued.)

ROSE JOSEPH LOWE.

THIS exquisite Rose combines in its bloom all the good points of *Mrs. W. J. Grant* as far as size and shapely petal are concerned, and also the lovely colouring of *Mme. Abel Chatenay*. It is, in fact, one of our best bedding pink Roses; its freedom of blooming, erect growth and the beautiful form of the flowers are perhaps unequalled by any other pink variety grown.

Being a sport of *Mrs. W. J. Grant*, we cannot look for great vigour, for we all know how the latter fails us at times; but given a good depth of soil and hard pruning, *Joseph Lowe* should be a success in most gardens. I would caution the grower to earth up the plants in

winter, for it is not one of our hardest kinds, although by taking this precaution one need not fear any ordinary winter. P.

LAYERING MOSS ROSES.

Moss ROSES are very charming in the garden; even isolated plants look well and prove attractive; but the best effect is produced when whole beds are devoted to these plants. The varieties may be mixed, but beds of distinct colours are the best. For every purpose Moss Roses are favourites, and few can excel them as button-hole flowers. The plants must be close pruned and well fed. As a general rule, they do not receive this treatment, very little pruning being done and but little manure given. When hard pruned some strong basal shoots grow, and these are good for layering; few real sucker shoots grow. Shoots layered now should be allowed to remain covered until next autumn twelve months, as it is rarely that the shoots root sufficiently to be removed the following winter. Some good loam, a small quantity of sweet leaf-soil, and plenty of coarse sand or road grit form a nice layering compost. More fibrous roots, however, will grow if some small pebbles are mixed with the compost at the rate of one peck to two bushels. The shoots must be held securely in position by strong wire pegs, and during the summer-time the compost must be kept in a consistent state of moisture. Amateurs who wish to form a collection of Moss Roses should plant the following six varieties first, namely, Baron de Wasenær (light crimson), Blanche Moreau (pure white), Old Pink (pale rose, full and well mossed), Celina (deep crimson), Zenobia (satin rose, full, well mossed) and Deuil de Paul Fontaine (crimson, well mossed, a very strong grower, looks well on a low trellis).

PAVED ROSE GARDEN AT ISLAND, STEEP, PETERSFIELD.

NEW AND RARE PLANTS.

FIRST-CLASS CERTIFICATES.

Nephrolepis exaltata muscosa.—An American sport from *N. e. superbissima*, whose chief characteristics are firmness, dwarfness and great density. The plant is dwarf and compact, the fronds being very thickly set. It is quite distinct even among the many that have preceded it. From Messrs. H. B. May and Sons, Edmonton.

Plagianthus Lyallii.—This white-flowered New Zealand shrub has been doing uncommonly well this year. It is a plant of great beauty when the drooping flowers on slender pedicels are seen in such abundance as presented. Exhibited by Messrs. Robert Veitch and Sons, Exeter.

Cattleya Warscewiczii alba Firmin Lambeau.—We had no opportunity of seeing this remarkable plant, which was early removed from the hall, but the fact that, in addition to a first-class certificate, the committee recommended that it be awarded a gold medal is the best proof of its unique character and excellence. It was exhibited by M. Lambeau, Brussels.

AWARDS OF MERIT.

Odontoglossum Epicaste (O. Clytie × O. crispum).—The flowers are of a blackish maroon, distinctly bordered with purplish mauve. It is very distinct.

Zygopetalum Brewii (Z. Perrenoudii × Z. rostratum).—Sepals and petals greenish, lip blotched reddish purple and broadly margined with white. These were exhibited by Messrs. Charlesworth and Co., Hayward's Heath.

Patrinia palmata.—Quite a remarkable and interesting novelty from Japan. The plant is about

profusely in a terminal head. It is a highly-attractive subject of distinctive colouring, and merits general cultivation. A splendid basket of plants a foot high was exhibited by Mr. Bain, gardener to Sir Trevor Lawrence, Bart., Dorking.

Astilbe Rhenania.—The flowers of this variety are of rosy pink colouring, with a strong suspicion of electric blue at the tips of the sepals. From Mr. Profittlich, Twickenham.

Nymphæa formosa.—A fine Marliac hybrid Water Lily, with handsome flowers coloured pale rose with deep yellow centres.

Nymphæa Attraction.—Another Marliac hybrid of handsome proportions. The flowers are coloured deep red, shading to rose towards the edges. This fine pair of Water Lilies came from Mr. J. Hudson, gardener to Mr. Leopold de Rothschild, Gunnersbury.

Gladiolus primulinus hybrids, to be known as the "Lang-Prim" hybrids, and which embrace shades of rose, salmon and yellow. Award of merit for the strain. From Messrs. J. Kelway and Son, Langport.

NEW FRUIT.

Peach Royal Charlotte.—An award of merit and cultural commendation were given this variety, of which the kernels were the only evidence remaining. From Sir Trevor Lawrence, Bart., Dorking (gardener, Mr. W. Bain).

All the foregoing were shown before the Royal Horticultural Society on the 16th inst., when the awards were made.

NOTES ON GARDEN DESIGN.

Not the least notable feature in the re-birth of interest in garden affairs during the last twenty years is the attention given to right design as well as to cultural success. The formal garden has come into its own again after long languishing in contempt. While the broad principles which govern its lay-out are generally accepted, extravagance has sometimes been shown in their application. It is therefore proposed to illustrate frequently in THE GARDEN such features as steps, paved parterres, pools, pergolas, &c., which are of unquestioned merit. The accompanying photograph shows the paved Rose garden at Island, Steep, Petersfield, designed by Messrs. Unsworth and Inigo Triggs. The latter is well known for his fine books on garden design, and we are entitled, therefore, to expect interesting work from him. The paved walks are so contrived that every Rose can be reached dry-shod without crossing grass. In the middle is a small, round pool, which serves to focus the design. The paving is laid "crazy fashion," and accords pleasantly with the dry-stone retaining walls which surround the sunk portion of the garden.

L. W.

GARDENING FOR BEGINNERS.

THE LAYERING AND PLANTING OF STRAWBERRIES.

THE cultivator of the Strawberry reaps a quick return for his labour. Few kinds of fruit entail less labour than does the Strawberry, but good work must be done at planting-time, and strong plants put in if the best crops of fruit are to be realised.

Layering.—Although a strong plant yields many runners suitable for layering, it is not advisable to layer more than one on each runner, and that should be the one nearest the parent plant, all others being discarded. From three to six plants may be raised from each parent plant. The necessary runners must be layered as early as possible, so that the young plants can be put out in their permanent quarters and get well established before the winter months come. Plants so treated will bear a good crop of fruit the following year, and much earlier than those planted late in the season. The runners may be layered in small pots or in squares of turves. Fig. 1 shows an old plant in a pot which has produced two runners, one of which is shown layered in a small pot. Old plants in beds produce layers in this way. The compost must be good. Fibrous loam, two parts; leaf-soil, one part; rotted manure, passed through a 1-inch-meshed sieve, one part; with a small quantity

1.—OLD PLANT IN POT WITH RUNNERS.

2.—LAYER ROOTED READY FOR PLANTING.

of sand added, will form a suitable compost. Peg down or place a stone on each runner in the pots. The runners on border plants must be layered in a similar way. Fig. 2 shows a strong-rooted layer ready for planting.

The Position for the New Bed.—This must be an open one for the main crop, away from tall trees or buildings. For very early cropping a few rows of plants may be put out on a sheltered border facing the south.

Preparing the Ground.—In every instance where young plants are to be put out it is essential that they be planted in deeply-dug ground. At this season the soil may be deeply trenched, and made moderately firm again by treading in the short space of two days, because the soil is not too moist. A naturally poor soil must be enriched by the addition of some well-rotted manure, and this should be supplemented by top-dressings of manure after the planting is done. Trench the soil two spits deep—twice the depth of the spade—and, in addition, fork up the subsoil, but leave it below. All fairly large lumps of soil must be broken up, and

for this purpose a garden fork will be found very useful. A rich soil need not be manured when dug; the top-dressings will be sufficient.

Planting.—Early planting is advisable, and so no time should be lost in getting the rooted layers put out in their fruiting quarters; but it is a good plan to first place the young plants in the pots on the north side of a wall or fence for three days when severed from the parent plants. If given such shelter and syringed twice daily they will receive no check to growth. A Strawberry plant is at its best the second year after planting. Renewal is generally advisable at the end of three years. In many cases valuable space is wasted owing to the young plants being put out too far apart. The strong-growing varieties should be planted 2 feet apart each way; the varieties with smaller leaves and a less robust habit will do well at a distance of 20 inches each way. One hour prior to planting thoroughly water the young plants in the pots. Fig. 3 shows on the left a plant with cramped roots. This is a bad way to plant. On the right a plant with the roots spread out is depicted, and the

arrow indicates the right depth to plant. This is the correct way. In planting, a hand-trowel should be used. The hole must be made large enough to contain the roots without cramping; the crown of the plant must be above the soil-level, and the soil should be firmly pressed round the roots with the hands. The greatest care should be taken to prevent soil getting into the hearts of the young plants; if it does, growth is severely checked and the plant may be killed outright. Give water and mulch the surface with very short, well-decayed manure, if obtainable.

G. G.

3.—ON THE LEFT, PLANT WITH CRAMPED ROOTS—BAD WAY TO PLANT. ON THE RIGHT, ROOTS SPREAD OUT. ARROW INDICATES DEPTH TO PLANT.

GARDENING OF THE WEEK.

FOR SOUTHERN GARDENS.

The Flower Garden.

The Summer Bedding.—The generally dull, damp weather we experienced greatly helped the various subjects after planting. At the time of writing we are having a spell of warm weather, and copious supplies of water overhead with a rosed can should be given the beds in the evening. Keep the various subjects tied up as growth is made, and the Dutch hoe going where space permits, as this is beneficial to growth, and also adds to the attractiveness. Faded flowers should also be removed weekly.

Violets.—These, too, have made good growth, and now should be frequently Dutch-hoed; also cut off any runners from the plants. A dusting of soot over the ground on showery mornings will prove helpful, as will some patent fertiliser. Damp the plants over well on warm evenings; this will help growth and also preserve it from attacks of red spider.

The Rose Garden.—Keep the plants in the beds as attractive as possible by removing the faded blooms, aerating the surface soil and keeping the ground free from weeds. Plenty of water at the roots in dry weather and syringings overhead will keep the foliage clean and do much to ward off attacks of mildew. Should the latter enemy prove troublesome, the foliage should either be syringed with a good specific or the foliage dusted with flowers of sulphur, using that known as black, as it is not nearly so conspicuous.

Climbing Roses.—The climbers, as they pass out of flower, may be given a thorough syringing with a good insecticide after having lessened some of the growths. There is nothing gained by allowing them to become crowded and tied in one on top of the other, so thin out liberally the oldest wood, leaving, of course, sufficient young wood to cover and thoroughly mature.

The Hardy Fruit Garden.

Raspberries.—After the fruits are cleared from the bushes, remove the nets and cut out from the base the old fruiting canes to admit light and air to the young growths. Keep the ground free from weeds around them, and loosen with the hoe.

Strawberries.—The beds when cleared of the fruits and no further runners are required should be overhauled, the runners cut off, and any damaged leaves and rubbish cleared away.

Peaches and Nectarines out of doors, in order to keep the foliage in a healthy condition, must be well syringed, and heavy waterings given at the roots. The foliage should be kept tied in as neatly and straightly as possible to the old wood. When the fruits have finished stoning, the crop, if too thick, must be thinned out to the requisite number and exposed to the light and air, and the use of insecticide washes abandoned, otherwise the fruits will become stained and unfit for dessert.

The Kitchen Garden.

Runner Beans.—Every encouragement should be afforded these to crop freely, and if the weather is dry, heavily water and see that the ground is protected with a heavy mulch. The growths may be regulated and weakly shoots thinned out if too thick, and the plants will enjoy a syringing after hot days. When picking, select those that are ready as near as possible. If required for exhibition, the clusters of young Beans should be judiciously thinned and marked accordingly.

Dwarf Beans.—Where one has the convenience of a cold frame or two, a sowing of the above made now will, with a little care and attention, provide a dish or two when the Runners and those out of doors are past. Draw wide drills about a yard apart and sow a double row thinly, as there is nothing gained by overcrowding, and the plants may be thinned again. Frames that have done for Potatoes will need but little extra attention, except the addition of a little Mushroom-bed manure. Keep well damped, admit abundance of air, and as soon as germinated keep a sharp look-out for slugs. Dust with soot occasionally.

Plants Under Glass.

Stocks.—One or two sowings made now will produce good flowering plants for the embellishment of the greenhouse next spring. The plants from the time they germinate must never be

coddled, but be grown on quite coolly to make sturdy plants. Sow the seed in a box or pan, or a pinch of seed can be sown in the centre of a 3-inch pot, and the seedlings thinned to the best plant. The young plants should be stood on a cool ash bottom and out of bright sunshine, and be carefully watered and kept syringed. The second sowing may be made towards the end of next month.

Mimosa pudica.—The Sensitive Plant is one of the most interesting plants for the greenhouse, easily raised from seed, and nice plants may be had in 5-inch pots. Until the plants get sufficiently large they may be accommodated in a cold frame. Water carefully until the roots are active, when waterings once a week or so with diluted liquid manure will greatly assist them.

Eucalyptus globulus.—This is a fine plant for room and decorative work generally. Plants the pots of which are full of root must be fed liberally. Clay's Fertilizer is an excellent manure for such subjects, applied alternately with liquid manure. Pot on the young plants that were raised this season as becomes necessary.

Cucumbers.—At this season these require constant attention to the regulating and thinning of the growth, otherwise it will soon get congested. Apply top-dressings to the bed frequently, and water copiously, using stimulants freely. The growths must be kept stopped at two joints beyond the fruits. Keep the foliage thoroughly well syringed, and if spider is in evidence, syringe late in the evening. Sow for another crop.

Tomatoes.—These are bearing profusely, and will need abundance of water and feeding. When the plants have reached their limit, stop the leading growth, and, if necessary, thin the foliage judiciously. Another sowing may now be made for supplies at a later date.

E. BECKETT, V.M.H.

Aldenham House Gardens, Elstree, Herts.

FOR NORTHERN GARDENS.

The Flower Garden.

Carnations.—By all means endeavour to finish layering within the current week.

Dahlias.—Slips from near the collar of the plants will strike root if placed where the cuttings are kept from flagging. Much attention will be needed to keep strong-growing plants securely tied, and to thin the growths so that they do not become overcrowded a few weeks later. By timely attention very much unnecessary labour afterwards is saved.

Starworts.—Any of the tall-growing midseason sorts that are growing too tall may be safely stopped. They will bloom slightly later, but the plants will give a denser mass of colour. It is, of course, essential to discriminate, those of the Nova-Engliæ section being best left to Nature, and Climax also, on account of its late flowering in the North.

Rose-beds.—The practice of planting an undergrowth among Roses sometimes leads to ridiculous results through the carpeting plants overtopping the Roses. This should not be, and, before it is evident, cutting back, thinning, or pinching should be pursued to preserve the Roses in the superior position. I have seen Lavender very effectively used; but the same colour may be had by using *Nepeta Mussinii*, and so with other flowers.

The Rock Garden.

Cyclamen.—The early-flowered species has now matured seeds, which may be sown at once in pots or boxes, to be placed in a cold frame. The seeds sometimes germinate freely round the mother plants, but better results are obtained if they are sown as above.

Double Sweet William.—The dwarf hybrid, presently a sheet of crimson, sometimes dies off quite unexpectedly. Where this occurs it is worth while to relieve portions of the clumps of their flowers, scattering among them some light compost, and watering it in if the weather continues dry. From these portions splendid self-rooted cuttings are to be had in September.

Orchis foliosa.—This has been very fine in a shaded moist corner, and, now that it is going off, the spikes should be removed lest seed should form and the plants be weakened for another year.

Arenaria balearica.—Nothing can be prettier than star-gemmed masses of this lowly alpine, but

it becomes a nuisance when it is permitted to overrun every bit of stone within its reach. This is a suitable time to reduce it to proper proportions now that it has done flowering, pieces being pulled away here and there, and not by any means trimmed. It is a most useful plant to cover otherwise impossible portions of walls.

The Vegetable Garden.

Onions.—Sow seed at once for plants to stand over the winter, either for transplanting or to draw young.

Scotch Kale.—Plant out immediately the young plants are large enough. To do them well, allow at least 2 feet each way. If set in fertile soil they are better if not manured, and, once started into growth, the ground, if loose, should be firmed by foot trampling. These means are effective in reducing losses during extreme frosts.

Herbs.—A sharp eye must be kept on any that are getting at the stage for gathering to dry. Thyme stands the winter all the better when the flowering stems are removed, and a new growth made and hardened before winter sets in. Late pickings of Sorrel may be had if the old leaves and stems are removed and the beds dressed with a compost rich in manure, such as that from Mushroom-beds.

The Fruit Garden.

Strawberries.—All but the latest will now be past, though in many gardens all kinds have been very scarce. Now the beds should be thoroughly cleaned, rooted runners required for planting being first lifted. The ground should be made firm after digging.

Worn-out Beds.—These should be destroyed at once. My plan is to cut over the plants by means of a sharp spade, with which the workman rapidly runs along the rows at the ground-level. The plants, after lying a few days to dry, are gathered into heaps and reduced there and then to ashes, and when time permits the ground is cultivated either by deep digging or trenching, the latter the preferable way.

Rooted Runners.—These usually are arranged close in rows to await ground becoming vacant and prepared for their reception. A thin coating of old Mushroom-bed manure is spread on the ground first of all, and is mixed with the soil in planting, which need not be more than 4 inches in depth. In the course of a few weeks each plant makes for itself a nice ball of fibrous roots.

Ripening Fruits.—The earliest fruits of Rivers' Prolific Plum usually ripen enough now to be used for cooking. This year Plums are so scarce that it may be wise to keep even these for preserving. Occasionally, too, fruits of Peach Early Beatrice ripen thus early on a south wall. It is therefore necessary to examine this and Hale's Early from time to time.

The Plant-Houses.

Primula obconica.—The latest batch of this useful plant should now be placed in 6-inch pots, using extra drainage and not potting over-firm. Return the plants to a cold frame and ventilate only in the daytime, damping the frames in the afternoon and shutting them up every night. They will under these conditions be nice flowering plants by October or November.

Coleus thyrsoides.—These, too, should get a final shift, and may be flowered in 5-inch to 8-inch pots. Keep them growing freely in a stove with light and ventilation, and pinch the tips of the shoots in order to make the plants bushy.

Hippeastrums.—Any plants that have stopped growing must be sparingly watered and given cooler quarters, so that they may go slowly to rest. Offsets growing in cutting-boxes will continue growing for some time yet, and must not be deprived of water at the root.

Cœlogyne cristata.—This useful Orchid is now growing rapidly, and if the plants have not been repotted recently, very diluted manure-water will be beneficial now that roots are being freely produced. A temperature of 60° to 65° suits them well, with free ventilation in fine weather.

Chrysanthemums.—A constant look-out must be kept for the first appearance of aphid, and the points of the shoots at once dusted with Tobacco powder. Tie the shoots well out so as to allow the air to pass freely among them, and as soon as the nights become cool watch for mildew, dusting the leaves with flowers of sulphur wherever it appears.

R. P. BROTHERSTON.

Tynningham, Prestonkirk, N.B.

**ANSWERS
TO CORRESPONDENTS.**

RULES FOR CORRESPONDENTS.

QUESTIONS AND ANSWERS.—The Editor intends to make THE GARDEN helpful to all readers who desire assistance, no matter what the branch of gardening may be, and with that object will make a special feature of the "Answers to Correspondents" columns. All communications should be clearly and concisely written on one side of the paper only, and addressed to the EDITOR of THE GARDEN, 20, Tavistock Street, Covent Garden, London, W.C. The name and address of the sender are required in addition to any designation he may desire to be used in the paper. When more than one query is sent, each should be on a separate piece of paper. Plants for naming should be clearly numbered and securely packed in damp grass or moss, not cotton-wool, and flowering shoots, where possible, should be sent. It is useless to send small scraps that are not characteristic of the plant. Letters on business should be sent to the PUBLISHER.

FLOWER GARDEN.

SWEET PEAS (No Name).—To secure the most bloom from your Sweet Peas, let them grow freely, water them according to necessity, feed them generously, and pick every flower-stem immediately, or just before, it reaches perfection. This will spell quantity, but one would not care to promise that the quality will be superlative.

VIOLA DISEASE (Reader).—The Viola foliage is attacked by the rust fungus (*Puccinia violae*). It is difficult to deal with, for it spreads very frequently from wild Violets to garden forms; but all attacked parts of plants are best destroyed. It is not, however, usually a very serious pest. Perhaps spraying with a rose red solution of potassium permanganate would do good. The leaf-curl of the Roses is the work of the Rose sawfly, which lays its eggs in the leaf, causing it to curl. Probably spraying it with lead arsenate (which is best purchased in the paste form) would be a means of destroying the larvæ if the spray were applied, say, at the end of May, before the leaves curled. The best means would be to remove the top 2 inches or 3 inches of soil from under the bushes some time during the winter, and either burn it or bury it deeply. The pupæ are present in this, and this would be a means of getting rid of them. The black spot on the Roses is due to the fungus *Actinonema roseæ*, and spraying with liver of sulphur, or with Bordeaux mixture, commencing immediately, is, next to hand picking, the best means of checking its spread.

THE GREENHOUSE.

CYCLAMEN (M. T. V.).—The leaves of Cyclamen have been very badly attacked by that insidious insect of microscopic proportions to which the name of Begonia mite is usually applied, from the fact that it was first noted on these plants. The greater part of the mischief is done while the leaves are in a young state, though the damage is more apparent afterwards. It can be destroyed by dipping in one of the several preparations of nicotine now to be obtained, following closely the instructions supplied with it, as these preparations vary in strength. Vaporising with XL All Vaporiser will also keep this mite in check. The ravages of this mite are greatly on the increase, and it now attacks a number of indoor plants, particularly if they are subject to a dry atmosphere.

TREES AND SHRUBS.

THE CRICKET-BAT WILLOW (C. H. F.).—The true cricket-bat Willow is an upright-growing form of *Salix alba cærulea*. Cuttings may be obtained from Mr. Shaw of Messrs. Shaw and Shrewsbury, cricket and general sports outfitters, Nottigham, or the Estate Agent, Estate Office, Copped Hall, near Epping, might be able and willing to give other addresses.

UNCOMMON WALL SHRUBS (David).—The following kinds of shrubby plants will be suitable for your walls. Some bear showy flowers in May, and others are remarkable for coloured fruit and foliage in autumn: *Ceanothus rigidus*, *C. veitchianus*, *Halesia corymbosa*, *Crataegus crenulata*, *Cotoneaster bullata*, *Clematis montana rubens*, *Vitis Henryi*, *Vitis Thunbergii*, *Escallonia exoniensis*, *E. langleyensis*, *Magnolia Watsonii*, *Sophora vicifolia*, *Abelia triflora*, *A. florihunda*, *Jasminum humile*, *Actinidia chinensis*, *Lonicera sempervirens*, *L. Henryi*, *Viburnum macrocephalum* and *V. utile*.

ORANGE TREES (M. P. H.).—From the appearance of the leaves of your Orange trees sent for examination, we have no hesitation in saying that root trouble is the source of the mischief. One or more of several things may have caused this. Defective drainage, improper soil, or over-watering would all be conducive to such a condition. We suggest that the plants be turned out of their pots and the roots examined. If the drainage is bad, remove it and supply fresh, while, if the roots do not appear to be healthy or the soil seems to be sour, remove as much of the soil as possible from among the roots with the aid of a pointed stick. Then repot in clean pots which have been well drained with thoroughly clean crocks, and repot into a compost made up of three parts good fibrous loam (not broken very small), half a part leaf-mould, and half a part broken sandstone and coarse sand. A small quantity of half-inch bones may be mixed with the soil if the roots are fairly healthy. Do not give any pots larger than is absolutely necessary, and root

firmly. After potting, place the plants in a moderately close and moist house which can be shaded from bright sun, and keep the plants well syringed several times daily. Water very carefully at the roots. About August stand the plants out of doors for a month or so; then remove them to a greenhouse for the winter.

ROSE GARDEN.

ORANGE FUNGUS AND BLACK SPOT (W. G.).—The two Roses are rather badly attacked by the two fungi named above. The red rust, or orange fungus, is so abundant on wild Roses generally that it is almost impossible to keep it from our cultivated Roses. The fungus will live through the winter, so that all leaves from affected plants should be burnt, and if they are carefully gathered up, and those on the bushes removed also, and put into a fire, much, if not all, of the fungus will be destroyed. Where trouble has previously existed, the bushes should be sprayed in spring, just when the leaves are expanding, with a solution of sulphide of potassium (one ounce to ten gallons of water), and if the rust appears in the wood, paint the parts with a solution of methylated spirit and water in equal parts. Black spot is a fungus that does not appear much before midsummer. Badly-diseased leaves should be removed and burnt. There is at present no known cure for black spot, but spraying with Bordeaux mixture, if commenced early enough, will certainly help to keep it in subjection.

MARECHAL NIEL (A. R.).—When one is able to devote the whole greenhouse to a plant of this Rose, the best method of treatment is as follows: The two main branches should be brought down and trained horizontally, one to the right and the other to the left. As we assume at present these two growths are growing perpendicularly, or nearly so, on the roof, you should now fit the roof with wires about fourteen inches apart, as for Vines, and retain one young growth for each wire, rubbing off all the others, as we understand from your letter that you have cut back the growths that have blossomed almost to their base. During the summer suppress all growths, excepting those in the wires, and encourage these latter all you can by liberally watering with liquid manure at intervals. Plenty of solar heat and atmospheric moisture will also assist growth immensely, so that to secure the heat you must not give too much ventilation, and be careful to close the house at 4 p.m. If the plant is a really thrifty one, your rods will reach the top of the wires, and probably more; but do not check them in any way, as they will cease growing in late autumn. From these rods the next season's crop of blooms are obtained, and the object should be to see that they are well ripened by the autumn. In the spring, when the buds seem to be ready to start, release the rods and let them droop away from the roof for a time, so that the lower eyes may start out also. As soon as the blooming has ended, these rods are cut down to the main arms again, and the same process is adopted for the new rods next summer.

FRUIT GARDEN.

APPLE TREE (L. H.).—Your tree is attacked by the canker fungus (*Nectria ditissima*). Cut out and burn the affected branches, and paint the wounds with lead paint or Stockholm tar.

PEARS CANKERING (G. H.).—The fungus causing the cracking of Pears is, no doubt, the Pear scab fungus (*Fusicladium pyrami*). It attacks not only the fruit, but leaves and shoots as well, and spraying should be done with Bordeaux mixture before the buds open, and again as soon as the petals have fallen.

YOUNG VINES SHANKING (N. M.).—It is not an uncommon thing to see Grapes shanking on young Vines such as yours when bearing only two or three bunches. What is the cause of it in such cases it is difficult to say, but we think it must be in consequence of derangement in the flow and distribution of the sap to the branches, some one or more constituents necessary to the healthy development of the berries being absent. If the Vines are robust and healthy, you will find this will disappear as the Vines come into normal bearing. If the Vines are not robust, then the trouble must be looked for at the roots. Shankling is not an inherited disease.

PYRAMID GOOSEBERRY TREES (J. B.).—To grow Gooseberries for profit there is no better way than to grow them as bushes in the ordinary way. Grown as pyramids the trees are more ornamental, and the fruit is more exposed and easily picked. The way to train these is to encourage the centre branch to grow upwards, and to prune the side shoots so as to form a cone. Your best way would be to buy young trees with the foundation of this training laid, notice how they are pruned, and follow the example. They can be bought very cheaply.

KITCHEN GARDEN.

TOMATOES (P. J.).—We have been unable to find any trace of insect or fungus on the Tomatoes to account for the discoloration of the foliage. It is probable that they have insufficient potash, and we should recommend you to try watering with sulphate of potash now and then at the rate of 1½oz. to the three-gallon can.

POTATO STEM ATTACKED (H. C. R.).—The grub feeding in the stem of the Potato is that of the minute moths (*Microlepidoptera*), but we are not sure of the species. It has been met with two or three times this year, but we can find no record of its occurrence in these islands before, though it is reported from Algeria. It would be well if you could breed out the moth so that it could be identified.

TIME TO SOW VARIOUS SEEDS (S. H.).—Too early sowing is usually the cause of Cabbage bolting in spring. The following Cabbage may be safely sown on August 10: Sutton's April Flower of Spring and Ellam's Early, also Offenham and Feltham. Enfield Market should be sown ten days later. You may make a small sowing of the Onions mentioned now (these will make fine bulbs if they do not bolt). Your main sowing should take place about August 12, the object being to get fairly strong plants before the winter, but not too large or strong.

MISCELLANEOUS.

"JULIENNE" (L. E. D.).—The name of Julienne is applied to several plants, but it is likely that the one to which you refer is *Hesperis matronalis*, belonging to the Order Cruciferae, and known under the various names of Julienne, Julienne des Jardins, Dame's Violet and Rocket. It is usually treated as a biennial, and seeds are sown about May or June one year to produce plants to bloom about the same time the following year; sometimes, however, plants may be kept for several years. There are numerous forms which differ principally in the colour of the flowers, but one form has double flowers. Other plants to which the name of Julienne is applied are *Malcolmia maritima* (Julienne de Mahon) and *Barbarea vulgaris* (Julienne Jaune or Yellow Rocket-Herb); the former is a cruciferous plant found wild on the shores of Kent, but not truly British, its home being in Southern Europe. It has small white or purplish flowers. *Barbarea vulgaris* is a British plant, which is known as Land Cress or Common Winter Cress. A common weed, it is found in gardens on waste land, &c. The flowers are yellow. A cultivated form with double flowers is the French *Julienne Jaune*, the type in France being spoken of as *Barbaree* or *Herbe de St. Barbe*. This also belongs to the Cruciferae, though we suggest that the common Rocket is possibly the plant you require. It would not be difficult for you to obtain all three; then you could decide which is the plant you require. Messrs. Backhouse, nurserymen, of York would doubtless be able to supply the specimens, for they include in their business a scientific branch for the purpose of supplying schools, institutions, &c., with specimens.

NAMES OF PLANTS.—Colonel H. M.—*Veronica ligustrifolia*; *B. Veronica speciosa*.—*M. A. R. C., Lincoln*.—*Thilia platyphyllos asplenifolia*.—*M. M. M.*—The fungus was beyond recognition on arrival. Kindly send again.—*P. H.*—*Robinia Pseudacacia dubia*.—*M. M. A.*—*Tragopogon pratense*.—*Mrs. E. B.*—*Good-yera repens*.—*W. Steedman*.—*Asplenium Filix-femina ramosa*.—*A. G., Awerkyne*.—*Linaria repens*; 2, *Dianthus deltoides albus*; 3, *D. Squieri* variety.—*Lady Evelyn Mason*.—1, *Lavandula spica nana compacta* (Dwarf French Lavender); 2, *L. spica* (the Old English Lavender).

SOCIETIES.

SOUTHAMPTON JUBILEE SHOW.

THE council are to be highly congratulated on the successful exhibition held at the County Ground, Southampton, on July 16 and 17. The weather was exceedingly hot, and reminded one of the sweltering days of July, 1911. By a judicious system of ventilation the tents were kept fairly cool, and this condition was much appreciated by exhibitors and public alike. The exhibition was one of the best that the society have held in Southampton; the arrangement of the numerous exhibits was, as usual, perfect, and reflects much credit on the courteous secretary, Mr. Fuidge, and the members of the council.

Carnations, Sweet Peas, vegetables, fruit, Roses, herbaceous and alpine plants and cut flowers, groups of miscellaneous plants and table decorations made a magnificent display; particularly fine were the exhibits of Messrs. Ladhams, Limited, Messrs. W. H. Rogers and Sons, Limited, Messrs. Webb and Sons, The Locksheath Nurseries and Messrs. Toogood and Sons. There were twenty-eight dinner-tables in competition, all lovely; they constituted a show in themselves. In such keen competition Miss Minnie Snellgrove won the two first prizes, and in an equally keen competition the first prize in the class for the most elegant epergne. Mr. Parton of Birmingham finally won the silver challenge cup in the amateurs' division for Carnations and Picotees. He again made the highest aggregate number of points in the vase classes, staging blooms of wonderful purity and freshness. Mr. James Douglas, Great Bookham, was a prominent prize-winner; he had grand flowers, which were greatly admired.

CARNATIONS.

In Class 1, for twelve vases of selfs, fancies and yellow-ground Picotees, Mr. Douglas won first position. Purity (premier bloom), Liberté, Pasquin, John Ruskin and Togo were very fine blooms. Second honours went to Messrs. Arthur R. Brown, Limited, Birmingham, a firm that staged some grand flowers; third, Mr. H. Mathias.

For four vases of Carnations, selfs, Mr. Douglas was first, Mr. Mathias second and Messrs. A. R. Brown third. Mr. Douglas had the best four vases of Carnations, fancies, Messrs. A. R. Brown and Mathias being second and third respectively.

Messrs. Brown and Douglas won in the order named in the class for four vases of Carnations, white-ground fancies.

In Classes 5, 6, 7 and 8 Mr. Douglas was the winner. In Division II, Mr. Parton won nearly all the first prizes, Mr. Linzee and Mr. J. H. Linington being also prominent prize-winners.

Mr. Linzee was very successful in the classes for dressed blooms on boards.

SWEET PEAS.

In the class for twelve distinct varieties Mr. Bealing was first. Mr. W. Bird, gardener to Miss Read, and Mr. R. Lawrence were second and third respectively. Stirling Stent, W. R. Beaver and E. Pearson were grand blooms in the first-prize collection.

Mr. F. Green had the best six varieties, Melba, Nettie Jenkins and Thomas Stevenson being fine blooms; second, Mr. Regan; third, Mr. G. Barnes.

Messrs. Toogood and Sons' first prize for nine distinct kinds was won by Mr. Usher, gardener to Sir R. Baker, Bart., M.P. He had Barbara, Thomas Stevenson, Nubian and Money-maker in fine condition. Second, Mr. Bealing. Some exhibits in this class were disqualified.

The first prize for nine distinct varieties, offered by Mr. Robert Sydenham, Birmingham, was won by Mr. Bealing.

Mr. Usher won the first prize for six bunches, offered by Messrs. Sutton and Sons; second, Mr. Hodson.

Mr. Bealing had the best vase of Sutton's Queen Sweet Pea.

Mr. Usher won the first prize for the best eight varieties, offered by Messrs. Webb and Sons; and also the first prize for six varieties, offered by Messrs. James Carter and Co.

ROSES.

The challenge trophy, for a representative group of cut Roses, to occupy a space not exceeding 50 square feet, offered by the Hon. Mrs. Eliot Yorke, was won by Mr. John Mattock, Oxford. It was a charming collection.

James Carter and Co., Mr. Ellwood was invincible, winning premier honours with produce of the highest quality, neatly staged.

MISCELLANEOUS SECTION.

Mr. E. Wills, Southampton, won in the open class for a group of miscellaneous plants arranged for effect; second, Mr. Turner, gardener to the Hon. Mrs. Eliot Yorke; third, Mr. Bealing.

In the class for a group arranged in a space of 80 square feet, Mr. T. Hall was the winner, also for a single flowering plant, staging *Clerodendron fallax*.

Mr. Hall scored in the classes for six *Caladiums* and six *Zonal Pelargoniums* respectively.

The heavily-laden fruit trees in pots exhibited by The Lockshead Nurseries were very fine, and attracted much attention.

NON-COMPETITIVE EXHIBITS.

Gold Medals.—To Mr. H. Burnett for Carnations; Messrs. E. Webb and Sons for vegetables, fruit and flowers; Messrs. H. B. May and Sons for Ferns; Messrs. Toogood and Sons for Sweet Peas; Messrs. W. H. Rogers and Son, Limited, for ornamental shrubs, Roses and rockery plants; Messrs. B. Ladhams, Limited, for rock garden, Roses and herbaceous cut flowers; and The Lockshead Nurseries for Carnations and fruit trees in pots.

Silver-gilt Medals.—To Messrs. A. R. Bide and Sons for Sweet Peas; Mr. C. W. Breadmore for Sweet Peas; Messrs. Jarman and Co. for cut flowers; Messrs. E. W. King and Co. for Sweet Peas; Mr. F. Longster for miscellaneous plants and Sweet Peas; and Mr. J. Stevenson for Sweet Peas.

The silver Rose bowl was won by Messrs. Frank Cant and Co., Colchester, who staged a fine lot of blooms; closely followed by Messrs. Harkness, last year's winners.

Mr. R. F. Felton very kindly decorated a table with Carnations and Asparagus Fern, which was most tastefully finished with the simplest devices, this being the primary object. He also helped with the judging of the tables and other floral classes.

There were ten entries in the class for table decorations, and the first prize fell to Mrs. Thomas for an artistic arrangement of Sweet Peas.

The trade exhibitors were represented by Messrs. W. Cuthbush and Sons, Barnet, who showed Roses and other flowers; Messrs. H. Newman and Son, Watford, Sweet Peas, Violas and sundries; Messrs. Gleeson and Co., herbaceous plants, &c.; and Messrs. Thomson and Charman, alpine and herbaceous plants.

LIVERPOOL HORTICULTURAL ASSOCIATION.

This society held a most successful show in the Corn Exchange, Liverpool, on the 17th inst., the exhibits filling every portion of the hall. Unfortunately, the hot weather had proved too much for the Queen of Flowers, so that a number of entries were not forthcoming. The general exhibits were somewhat undersized, but excellent in colour. The Sweet Peas were a great advance on anything yet seen in Liverpool, both in quantity and quality.

Roses.—Eighteen Hybrid Teas had only one exhibit, which secured the first prize for Mr. J. W. Parker, gardener to J. R. Dixon-Nuttall, Esq., Prescott.

For eighteen blooms, distinct, Mr. Parker was again the victor, his *Lyon* and *Lady Ashdown* being noteworthy.

For twelve blooms Mr. Aindow of Formby led with a handsome lot of well-shaped flowers; for six blooms Mr. W. Foulkes was first.

For twelve, in not less than six varieties, amateurs only, Mr. L. Thomson took the first; and for six blooms Mr. P. Fitzpatrick secured the favoured position. Mr. C. Green had the best vases, and Mr. C. Haeckey was the winner in the members' class.

Sweet Peas.—The class for twenty vases brought out a strong competition. Mr. W. Davies, gardener to Dr. G. H. Phillips, occupying the place of honour with fine flowers of excellent substance. Mr. R. R. Anderson proved a good second. Mr. W. Bond, gardener to J. P. Heron, Esq., also staged well.

For twelve vases Mr. W. Davies was again the victor, his *Nubian*, *Thomas Stevenson* and *Mrs. Harcastle Sykes* being extra good. Mr. H. Foulkes, gardener to Major F. M. Roome, Formby, and Mr. E. T. Barrett, gardener to E. Cozens-Hardy, Esq., Woolton, won the other prizes.

For a like number of waved standards Mr. H. Foulkes took the leading position with a good stand.

For twelve vases, distinct, Mr. J. George, gardener to Mr. T. Heushaw of Roby, was first; also for a similar number locally grown.

Mr. W. Bond secured Messrs. Sutton's special prize for Sutton's Queen.

For twelve vases, amateurs only, Mr. J. Roberts of Grosford had the leading lot; and for six Mr. R. Aindow was first. For the waved selection Mr. G. Faulkner proved successful. Messrs. E. J. Procter and J. Tapscott proved the champions in the members' section.

For a table of Sweet Peas Miss Newsham held the place of honour in strong competition, Mrs. H. E. Marsh winning for the table other than Sweet Peas with pleasing single bronze-coloured Roses.

Herbaceous Cut Flowers.—These were shown in quantity and enhanced the appearance with changes of colouring. Mr. J. George and Mr. Parker gave evidence that these flowers are still well cared for by some. Messrs. E. Sergenson and J. Green contributing their quota as amateurs.

Carnations and Picotees were well represented, Ann Hathaway, Miss Peggy and Lady Willmott being charming. The chief awards went to Messrs. James Calder, H. S. Barrett, R. Duke, E. Sergenson and J. Green.

Mr. Turnbull had the best *Pansies* and *Violas*; while Mr. W. A. Crippen showed the beauties of the single and double flowered *Begonias*.

Non-competitive.—Gold medals appeared to be dealt out with a free hand. These were awarded to Mr. R. Manson for a fine display of Roses; Messrs. R. P. Ker and Sons, miscellaneous plants, fruits and vegetables; Liverpool Orchid Company, Orchids and cut Roses; Mr. H. Middlehurst, Mr. R. Wright, Messrs. Aldersey and Marsden Jones, each for a collection of Sweet Peas; Messrs. Dicksons, Chester, Gladioli, Roses, &c.; and Bees, Limited, alpine plants and cut flowers.

Silver Medals.—Messrs. C. A. Young, West Derby, and C. Russell of Blandfords for Carnations and Picotees; the Covent Garden Company, herbaceous cut flowers; Mr. W. Rowlands, Childwall Nurseries, Roses; Messrs. Jones Brothers, assorted cut flowers; Messrs. Aitken and Faulkner, Tarvin, Sweet Peas; Messrs. Fishlock Brothers, floral decorations; and Mr. W. Hodgkinson, Gloxinias in pots.

A MAGNIFICENT COLLECTION OF VEGETABLES SHOWN BY MR. E. BECKETT AT THE ELSTREE SHOW.

Second honours went to Messrs. W. H. Rogers and Son, Limited, Southampton, who also had a lovely group.

Messrs. Perkins and Sons, Coventry, were first in the class for twenty-four cut blooms, distinct. *Avoca*, *Duchess of Sutherland*, *The Lyon Rose*, *Caroline Testout* and *Queen of Spain* were the best flowers. Messrs. D. Prior and Sons, Colchester, and Mr. Mattock were second and third respectively.

Messrs. Perkins, Prior and Mattock won in the order named in the class for twelve Roses, Teas or Noisettes.

Mr. Nicklen, gardener to Alan Searle, Esq., had the best nine, distinct, exhibition or decorative; and Dr. Lamplough the best twelve Roses, distinct.

FRUIT AND VEGETABLES.

These were of high quality and extensively shown. Mr. Baxter, gardener to Captain Dalgety, Ronsey, had fine Grapes, Peaches, Nectarines and a grand Melon in his first-prize collection of six distinct varieties of fruit.

Mr. Hall, gardener to Ellen Lady Swaythling, staged four perfect bunches of *Madresfield Court* Grapes, and won first prize.

Mr. W. Hall, gardener to Major Chichester, had the best pair of bunches in the class for two of white, staging *Muscot* of Alexandria.

Mr. T. Hall scored in the class for two bunches of black, staging *Madresfield Court*.

Mr. Ellwood, gardener to W. H. Myers, Esq., had the best green-fleshed Melon.

The Lockshead Nurseries had the best dishes of Peaches and Nectarines respectively.

In the classes for collections of vegetables, the prizes being offered by Messrs. Toogood and Sons, Messrs. Sutton and Sons, Messrs. Webb and Sons and Messrs.

Silver Medals.—To Mr. W. E. Alsen for Sweet Peas; Mr. H. Ellison for Cacti; Messrs. Wells and Co. for Carnations; Mr. C. Fay for Carnations; and Messrs. Hillier and Sons for Roses.

Award of Merit.—To Mr. Maurice Prichard for cut flowers of herbaceous plants.

ELSTREE AND BOREHAM WOOD HORTICULTURAL SHOW.

This society held its fourth summer show on July 10, and was again favoured with brilliant weather. Since its formation the society has been fortunate in having such ideal surroundings as the park and grounds of Aldenham House, kindly placed at their disposal by Lord Aldenham and the Hon. Vicary Gibbs, and the continued success is largely due to the kindly interest extended by these gentlemen. This year experienced a record attendance, also an increased number of entries in the competitive classes, and both in the open amateurs' and cottagers' classes excellent exhibits were staged. The honorary and trade exhibits were arranged in a separate marquee, and evoked considerable interest. At either end was a line group staged by the president (gardener, Mr. E. Beckett, V.M.H.), which were awarded a gold medal. One consisted of a fine collection of vegetables, one of the largest ever exhibited, including about a hundred dishes of excellent varieties, and the other was a model water garden, depicting a stream planted with *Water Lilies* and other aquatics, the banks and background being planted with *Rushes* and flowering subjects.

Edgar Greenwood, Esq. (gardener, Mr. G. Capell), staged a group of well-grown specimens of *Hydrangeas* and *Coleus*, and was awarded a silver medal.

EDITORIAL NOTICES.

Every department of horticulture is represented in **THE GARDEN**, and the Editor invites readers to send in questions relating to matters upon which they wish expert advice.

The Editor welcomes photographs, articles and notes, but he will not be responsible for their safe return. All reasonable care, however, will be taken, and where stamps are enclosed, he will endeavour to return non-accepted contributions.

As regards photographs, if payment be desired, the Editor asks that the price required for reproduction be plainly stated. It must be distinctly understood that only the actual photographer or owner of the copyright will be treated with.

*The Editor will not be responsible for the return of artistic or literary contributions which he may not be able to use, and the receipt of a proof must not be taken as evidence that an article is accepted. Publication in **THE GARDEN** will alone be recognised as acceptance.*

Offices: 20, Tavistock Street, Covent Garden, W.C.

NOTES OF THE WEEK.

Variation in Black Currant Boskoop Giant.—At a recent meeting of the scientific committee of the Royal Horticultural Society, Mr. Charles Pearson sent shoots of Black Currant Boskoop Giant to illustrate a variation which had apparently suddenly arisen in several localities. The leaves become much more dentate and the bushes fail to fruit. Sometimes only a portion of the bush is so affected, but frequently the whole, and in one plantation 50 per cent. of the bushes showed the variation. The committee would welcome any observations that would throw light upon the phenomenon. It has been suggested that possibly hard pruning may have brought about the result, but there is no record so far of reversion.

A Beautiful Hardy Heath.—*Erica cinerea* is our commonest British Heath, for, in companionship with the Ling (*Calluna vulgaris*), it is met with in all parts of the country covering commons and hillsides and making a blaze of colour from July to September. Although some difference of colour is noticeable among plants growing under natural conditions, there is no great variation from the typical crimson-purple. Horticulturists, however, have developed a number of varieties which differ widely in colour of flowers from the type, thus providing an excellent group of plants for the garden. Of these varieties alba and alba minor, with white flowers; *purpurea* and *atropurpurea*, with light and deep purple respectively; *atrosanguinea*, with deep red; *coccinea*, with scarlet; and *rosea*, with rose-coloured flowers, are among the most conspicuous. With the type and this set of varieties it is possible to create a very showy feature either in the wild garden, in beds on the lawn, or in the rock garden, the effect being, of course, most pleasing when each kind is used separately and with a generous hand.

Origin of Sweet Pea Countess Spencer.—The current issue of the Journal of the Royal Horticultural Society contains some new and interesting particulars concerning the origination of Sweet Pea Countess Spencer, the first variety with a waved standard. As all the world knows, Mr. Cole, at that time gardener to Earl Spencer, raised it in 1901, first by crossing *Lovely* with *Triumph*, and then the best of the progeny of that cross with *Prima Donna*. Now, in a letter to Mr. W. Cuthbertson, J.P., relating to a lecture on Sweet Peas given by him before the Royal Horticultural Society, Mr. Viner of Somerset Road, Frome, states that in 1901 he saw a spray of what we now know as *Countess Spencer* in *Prima Donna*, the seeds of which he saved, and the following year five out of seven plants retained the waved character. Blooms from these were shown at the Bath Show in July that year under the name of *Nellie Viner* and gained a certificate. Eventually Mr. Viner

disposed of the stock to Mr. Henry Eckford, who, learning that the variety *Countess Spencer* was similar, dropped the name of *Nellie Viner* and put his stock on the market as a superior *Countess Spencer*. Mr. Cuthbertson, in sending Mr. Viner's letter to the Royal Horticultural Society, states that he is practically convinced that *Countess Spencer* appeared as a mutation in *Prima Donna* in several places in Great Britain the same season.

The Flowering Rush.—The Flowering Rush (*Butomus umbellatus*) is an instance of a common British plant which is well worth introducing into the garden where it does not already exist, for several instances have been noted lately where its use has been attended by the happiest results. A marsh or water loving plant, it is excellent for using about the margins of a lake or stream, where it makes a change from the all too common Sweet Flag (*Acorus Calamus*). The Flowering Rush grows 3 feet to 4 feet high, and is so-called on account of its Rush-like foliage. That it is quite distinct from the ordinary Rushes is evident by its large umbels of rosy red flowers, terminating tall stems, which appear from late June to August, according to the locality. During the hot days of summer the bog and water garden, especially the latter, have a peculiar charm, and the opportunity should not be lost of jotting down any particularly effective plant with an eye to its introduction to other quarters at a fitting season. It is also a good time to plan alterations and a redistribution of plants, and while this is being done we specially commend the species under notice to the gardener's attention.

Australian Pepper.—Under this heading, in answer to a correspondent ("T. B. F.") on page 359 of our issue for July 13, we gave the name of the Australian Pepper Plant as *Piper Novæ-Hollandiæ*, which was perfectly correct, though the name Pepper Plant is also ascribed to *Drimys aromatica*. Some further facts relating to these two plants may be of interest to our correspondent, as well as to our readers generally. The Piper, which in the vernacular is known as the Climbing Pepper or Native Pepper Vine, is a native of New South Wales and Queensland, and is one of the largest Australian creepers, climbing, like Ivy, to the tops of the tallest trees. At one time it was well known in Australian medicine, having the reputation of being "an excellent stimulant tonic to the mucous membrane." The wood is coarse-grained, and very pungent when freshly cut. *Drimys aromatica* is a close ally to the well-known Winter's Bark Tree of the Straits of Magellan (*D. Winteri*), belonging to the Natural Order Magnoliaceæ, and at one time noted as an aromatic tonic. *D. aromatica* is a native of Tasmania, Victoria and New South Wales, where the fruit is used as a condiment. The leaves have a pungent cinnamon-like flavour, hence probably its name of Pepper Tree.

CORRESPONDENCE.

(The Editor is not responsible for the opinions expressed by correspondents.)

Myxomycetes.—In our note to Mr. Watts' letter on exhibiting Daffodils, which appeared on page 374 of last week's issue, this word, owing to a misprint, appeared as "Myxomyates."

Curious Laburnums.—There are quite a number of specimens of *Laburnum Adami* in Scotland. The curious thing is that people are so slow to learn of the existence of *Laburnum Adami*, although it is a comparatively common tree in places where out-of-the-way subjects of the kind are cultivated.—S. ARNOTT.

An Early Pear.—Pear Doyenné de Eté is very delicious this season and quite ready for use. The blackbirds find this out very quickly, and nets must be at once put over the tree, or the birds will soon make short work of the fruits, as they are very sweet and juicy. Anyone not growing this very early variety should make a note of it and plant it in the autumn. It is a free-growing variety and crops in a prolific manner. The fruits should, however, be consumed as gathered from the tree, as they will not keep.—W. A. COOK.

Rambler Roses.—I have never seen the flowers more richly coloured than they are this season. The variety Dorothy Perkins is flowering and growing more freely than in previous years, and the blossoms are very rich in colour. Many strong young shoots are growing beyond the trusses of flowers, and, unless they are required for filling up space, they must be cut out. The older wood should also be freely cut away where there are plenty of strong young shoots to take its place. This work ought not to be left until the end of the autumn or next spring, but be done at once.—B.

Rose Lady Godiva as a Weeping Standard.—I was glad to see the note on the above in THE GARDEN of July 27. Lady Godiva is really one of the very best Roses for this purpose, its slender, pliant growth and its lovely flowers giving it a most beautiful appearance when so grown. I saw, the other day, some fine weeping standards of Leuchstern, Gardenia, Una, Flora, Hiawatha, Aglaia, Ruby Queen, Dorothy Perkins and others, and none could surpass Lady Godiva in elegance. Gardenia is very fine in its way. By the way, I am glad to see that the writer of the note has a high opinion of Leontine Gervaise, which in my garden is one of the most beautifully coloured among a rather good variety of rambling Roses.—SUB ROSA.

Rose Conrad F. Meyer.—We can all appreciate "Avon's" remarks on this Rose, published in THE GARDEN recently. This plant is generally considered an obstinate Rose to grow practically in all parts of the country. "Avon" says he has seen a fine plant in the South. There is also here in Midlothian a fine specimen of this Rose growing over an arch doing as well as one could wish for. About a fortnight ago it was showing over four hundred blooms, and has every prospect of flowering for another month and more. The fault lies, as a rule, in trying to grow this Rose as a bush, and, in consequence, being severely pruned. This Rose simply hates the knife, and should hardly be pruned at all; but if allowed to grow over an arch or a similar device it will, I am sure, give every satisfaction by flowering profusely from June to September.—H. J. S.

Rosa nitida.—Lovers of the Rose species always find in the little *Rosa nitida* a plant worthy of admiration at practically any season. At present its main attractions lie in its glossy foliage and its lovely bright red or deep pink flowers, which are being very freely borne this season. Possibly, however, these charms of the summer are eclipsed by those of autumn, when the foliage passes off through shades of red, orange, &c., to almost purple, and when the branches show their deep red colouring, and the hips, which come freely, their bright scarlet among the foliage. *R. nitida* is only about two feet high, and as it grows freely it can be planted with confidence. It does not appear too fastidious as to soil, but I think it colours best on a poor and rather dry one. It soon increases by means of suckers.—S. A.

Rose Tea Rambler in Cold Districts.—Experience of the lovely Rose Tea Rambler modifies the high opinion one formed of it at first, and for cold districts or those subject to late frosts in spring it is to be feared a word of caution is necessary. It makes strong growths, which, however, are late in ripening and very liable to be destroyed in spring. This is the experience of the writer, but it is by no means an isolated one, as one finds on making enquiries among others who have tried this really beautiful Rose. It has many points of beauty, from its handsome foliage, the young strong shoots of which are so finely coloured, to the delightful flowers. One is, therefore, reluctant to do without it, yet a succession of seasons in which it has been badly cut makes one long for something like Tea Rambler, but more capable of standing late frosts in the colder parts of the country.—A.

The Scarlet Martagon Lily.—*Lilium chalcidonicum* shares with *L. croceum* and *L. candidum* the credit of being one of the best of garden Lilies, while the disease which often proves fatal to *L. candidum* does not trouble it. A member of the Martagon group, *L. chalcidonicum* always arrests attention by reason of its prettily-reflexed, bright red blossoms, which are, as a rule, borne from early in July onwards. In common with several others of the Martagon section, the stem roots are but sparingly produced; therefore the main support of the plant is derived from the stout, thong-like roots at the base of the bulb. From this circumstance it will be readily understood that *L. chalcidonicum* is scarcely likely to be seen at its best the first season after planting; indeed, it takes two or three years to become thoroughly at home. A deep, well-drained loam suits it well, and this, combined with its objection to removal, accounts for this Lily being frequently seen at its best in cottage or farmstead gardens, where the practice of letting well alone prevails to a great extent, and changes are decidedly infrequent.—H. P.

Fruiting of the Mulberry Tree.—In reference to the note on the flowering and fruiting of the Mulberry tree, page 361, July 20 issue, I should like to state what my observations lead me to think is the cause of fruit only being produced upon some branches and only catkins upon others. On taking charge of the garden here some twelve years ago, I advised my employer to let me cut back many branches of a very large old tree which overhung the grass and borders too much, and I continued to prune rather freely for the first four years. I did not notice any great difference in the fruitfulness of those branches not cut till three years ago, and this season it is more marked than ever, the parts pruned back being full of vigour and bearing berries only. Those branches that

have not been cut back have a very starved appearance and produce catkins only. I should, therefore, think the cause lies in the pruning and the fact that a large tree in full vigour so shades itself in various parts that its branches do not all get matured alike.—W. MANNING, *The Hermitage, Leawisham Hill, S.E.*

Judges Judged.—I was much interested in Mr. Jenkins' letters in the issues of THE GARDEN dated July 20 and July 27 respectively in reference to the disqualifications at the recent National Sweet Pea Society's Show. In my usual notes on the Queen of Annuals I alluded to the subject and took the same view as Mr. Jenkins—that the judges had no power to go beyond disqualification. My firm opinion is that the rules of a society are equally as binding on the judges as they are on the exhibitors, but this is not accepted by many adjudicators. I think it would be for the general good of horticultural shows if the Editor would secure the views of such renowned judges as Messrs. Owen Thomas, S. T. Wright, J. Jaques, James Hudson, N. F. Barnes, A. Mackellar and others who could be easily mentioned. The point is: Can judges alter the rules of a society to suit an occurrence? The question of double standards in Sweet Peas has no bearing on the principle involved.—HORACE J. WRIGHT.

—Mr. Jenkins, in his letter which appears on page 374, issue July 27, raises a very important point as to the legality of the action of the judges at the National Sweet Pea Society's recent show. As he rightly points out, the judges, in recommending for prizes exhibits that contained double standards, advised the committee to break a rule that was plainly printed in the regulations for exhibitors. That the committee, or at least those members of it who were present, should have consented to such an arrangement is, to say the least of it, astonishing, and, one would imagine, illegal. As one who has taken considerable interest in the Sweet Pea and its society, I must protest against such quixotic proceedings, which are not in keeping with the dignity of a National Society and against all recognised rules of judging.—A. B. ESSEX.

Rose Society for the City of London.—It has been suggested to me by several amateur Rose-growers that a Rose society should be formed exclusively for City people. The primary object would be to hold an annual show in the heart of the City. I am convinced that there is ample room for such a society. There must be a very large number of keen rosarians among our City workers, as indeed a casual examination of "button-holes" during the Rose season amply testifies. They would, I am sure, welcome an exhibition of Roses in their midst, for only a comparatively small number can afford the time to attend the metropolitan exhibition of the National Rose Society or similar shows. The schedule would, naturally, include classes to suit the smaller as well as the large growers, and I think should also have special ones for those dwelling within five and ten miles of the City boundary. Thus exhibitors would be competing against those who have to cultivate their Roses under similar conditions, and this would foster a spirit of keen but friendly rivalry between the various suburbs. I shall be very pleased to receive names and City addresses of those who would be willing to join in the formation of such a society, from which a committee could be formed to carry out the working details.—A. ERNEST PROTHEROE, 67 and 68, *Cheapside, E.C.*

The French Honeysuckle after Flowering.—This handsome shrubby plant is flowering with its wonted freedom with me this season, and the question arises whether it is preferable to cut it well back after flowering, or simply to trim the branches so as to keep the bush in the desired form. Each method has its advantages, and the former would appeal to those who want a compact bush, the latter suiting those who wish to have a tall and more loosely-disposed shrub. Its nominal height is stated as from 2 feet to 5 feet, and it can be had at either, according to the practice of pruning adopted. In any case it is a handsome plant with its racemes of from eight to ten flowers of a nice vermilion pink in the axils of the leaves. With me it is remarkably slow of showing growth each season, and to those who have not seen it before it looks as if it were dead until June, when it begins to show its foliage in a half-shaded place, which suits it well here and in dry soil.—S. ARNOTT, *Dumfries*.

Rose Conrad F. Meyer in a London Garden.—Looking up a note about this Rose, I find it was photographed on May 23, the earliest date, by the way, it has ever been so well advanced. The waiting of another couple of days would have given a better picture, I afterwards found, but the weather looked threatening, and so we made sure of what is now seen. The plant is about ten feet high, healthy and vigorous. Two years ago, thinking it was making too much top growth, we root-pruned it, an operation which has, apparently, justified itself. A most peculiar procedure has taken place this month with one of the strongest shoots. After growing strongly for some five feet, a growth has developed an unusual flower-head, consisting of twenty-five healthy buds, below this again being another shoot about a foot in length, which will go on and complete the ordinary length of growth. We have two other specimens of this Rose between 5 feet and 6 feet high, which I struck from cuttings three or four years ago. They flower well, but the blooms are not so abundant or so large as from the pillar plant. This, however may be a matter of age. The praises given by "An Essex Reader" to this Rose are well deserved, and I, too, should judge it to be a good hedge plant. The experience of Mr. Peel Sheldon concerning this Rose is rather perplexing, particularly as he mentions his result has been identical in two different counties. Nothing being said to the contrary in his note, I wondered, as a reader, whether he transferred the plants from Hampshire to Kent. If so, it is plain his plants are, for some past reason of treatment or selection of quality of plant, liable to develop the black spot on the leaves, and the best thing to do is to destroy the plants. On the other hand, if Mr. Sheldon's plants are fresh ones, and not those from his other garden, may I suggest his communicating with the nearest Rose nursery or private grower of some repute and making a few comparisons as to soil, treatment and the appearance

of their specimens of this Rose with his own. I think this plan might throw some light on the subject, and the result would be of interest and value to all Rose note readers of THE GARDEN.—C. TURNER, *Ken View Garden, Highgate*.

THE GREENHOUSE.

THE CULTIVATION OF THE PERSIAN CYCLAMEN.

FEW plants give the average cultivator more trouble, and few better repay good and proper treatment, than this. In only a very few gardens do we come across really fine batches of this plant. That it is not one of easy culture I must frankly admit; and having in the past had my full share of disappointments with it, I can fully sympathise with those who have hitherto failed to grow it to perfection. When badly grown, few plants give a more depressing appearance to a house or frame, while really fine specimens are among our grandest floral gems. I have grown these plants for over twenty years, and, until seven or eight years ago, with very indifferent success. Some years they were excellent, but more often miserable failures. Now, however, I invariably have a fine display each winter and spring, so a few details of my methods of culture may be of interest to some of the readers of THE GARDEN who, like myself, may be fond of this beautiful plant. As I consider that young plants are in every way more satisfactory than old bulbs, I propose to confine my remarks chiefly to the culture from the seed-sowing until the plants bloom the first time.

Sowing the Seeds.—I have sown at various times from August till January, and find that the best time is about the middle of the first-named month. Up till the middle of September will do; but if later than that, the plants will not, in my opinion, be so fine and floriferous as the early-sown ones. Select moderately deep pans 9 inches in diameter, and crock carefully and well. Over the crocks place some of the riddlings from the soil. The most suitable compost is made by mixing equal parts of the best loam and brown flaky peat, with a small quantity of leaf-mould and sufficient sharp sand to ensure the whole being kept nice and open. A few pieces of bruised charcoal may be added, if desired, as these help greatly to keep the soil sweet. Mix thoroughly and pass through a half-inch riddle. Scatter the seeds evenly and thinly, and cover with about a quarter of an inch of the soil passed through a quarter-inch riddle. Press gently, and then water with tepid water through a very fine rose. An intermediate temperature—60° to 65°—is very suitable during the autumn and winter. The pans should be covered with a sheet of glass and a piece of thick paper. As soon as growth shows, remove the paper and slightly tilt the glass. In due time the glass can be removed and the pans set on a shelf close to the glass. Shade from bright sunshine until November, and see that the soil is never allowed to become dry. At the same time, overwatering must be strictly guarded against. An occasional vaporising with XL All will keep the little plants clear of green fly, and, what is more to be dreaded, the Begonia mite, which very often attacks the Cyclamen.

Pricking Off the Seedlings.—Towards the end of January the little plants will be in the best of condition for pricking off into 2-inch pots. The same compost is suitable, with the addition of a sprinkling of Ichthemic Guano. One crock in the bottom and three or four small pieces of charcoal will afford perfect drainage. Pot very lightly, and on no account bury the little bulbs. Place the pots in ordinary cutting-boxes, in the bottoms of which spread half an inch of Cocoanut fibre or even leaf-mould. Give a good watering with tepid water to settle the soil, and then twice daily sprinkle overhead with clean tepid water from a very fine-rosed can. Vaporise as necessary to keep

from an old building, a 6-inch potful of bone-meal to each barrow-load of soil, and about half that quantity or a little more of Thomson's Plant Manure. Use the loam and peat in a fairly rough state, but pass the others through a half-inch riddle. Mix thoroughly, and use dry rather than wet. Make the soil only very moderately firm, and, as before, keep the crowns well up out of the soil. Give a good watering to settle the soil, and return to the greenhouse or pit, shading well from the sun and continuing the sprinkling overhead twice a day until October, when this should be gradually discontinued. I prefer to always grow the plants in a greenhouse or pit in preference

TREES AND SHRUBS.

A BEAUTIFUL HARDY SHRUB.

(*ESCALLONIA PHILIPPIANA*.)

THIS is the hardiest of all the Escallonias, growing in the open in the London district, for, as is well known, most of them require the shelter of a wall or belt of shrubs, except in the South and West. It is a native of Valdivia, and is one of Richard Pearce's introductions of the early seventies. *E. philippiana* forms a spreading bush some 5 feet in height. It is deciduous; with small rich green leaves. The shoots in late June and July are clothed with masses of starry white blossoms, with a fragrance suggestive of Hawthorn. Cuttings form a ready means of increasing Escallonias under glass from July to September. They thrive in a rich, well-drained, loamy soil.

The Escallonias are well-known seaside shrubs, being frequently represented as large bushes in shrubberies, or even as hedge plants in Devon, Cornwall and similar localities. The subject of this note is also interesting as being the seed-bearing parent of the valuable hybrid *Escallonia langleyensis*, the male parent being *E. macrantha*. This hybrid comes next in point of hardiness to *E. philippiana*, the unripe tips of the shoots suffering a little during severe winters. *E. langleyensis* has rich dark green leaves and rose red flowers produced in profusion during June, with a more or less continuous supply until autumn.

WEeping TREES FOR HOT WEATHER.

THERE are many trees with weeping or pendulous branches which might well be given prominent positions on lawns, especially when the lawns are used for afternoon teas, for on a hot summer's day the shade of a large Weeping Elm or Ash is very acceptable. A shady tree in the vicinity of a tennis or croquet lawn is also a valuable asset, for spectators may then enjoy watching a game without being subjected to the full glare of the sun, a very necessary consideration when people of delicate constitution are concerned. Apart from this, pendulous-habited trees are a necessity in a large garden from a landscape point of view, particularly in the vicinity of water, for they tend to relieve the monotony of trees of more rigid outline. Some consideration must be given, however, to the selection of the kinds of weeping trees, for all are not suitable for the same purpose.

As a whole, weeping trees may be divided into three groups, according to habit. One group is made up of trees on which every branch is pendulous, the whole branch system assuming more or less the outline of an open umbrella. Another group is composed of trees with an upright leader and moderately straight main branches with the secondary branchlets pendulous; while the third set consists of trees with a curiously-contorted habit of growth, in which the main shoots bend over almost at right angles, and yet the trees continue to increase in height without any attention on the part of the cultivator. As a rule, in such a case all side branches are long and pendulous.

When shade is the first consideration, the umbrella-shaped tree is the best one to plant, for the branches develop in a uniform manner and shade is provided all round. It is difficult to get some kinds of trees to the desired height without

SPRAY OF A HARDY ESCALLONIA, *E. PHILIPPIANA*, A USEFUL SHRUB FOR SEASIDE GARDENS.

down insect pests; but these will not be troublesome if a nice genial atmosphere be kept up. In due time the little pots will become well filled with roots, and it is desirable to give them a shift before they are actually pot-bound. While very good results are had by shifting directly into the flowering pots, I prefer to give them an intermediate shift.

The Second Potting.—Much the same compost is suitable for this, but it should be used in a rougher state. It is also beneficial to add a 5-inch potful of finely-ground bones to each barrow-load of compost, and a small quantity of dried horse or cow manure. Continue to pot loosely, and always keep the corms half out of the soil. Still sprinkle overhead twice a day, and shade from all direct sunshine. Three-inch and 4-inch pots are suitable for the second potting.

Final Potting.—This must be attended to before the plants get root-bound, or a check will be given that not infrequently causes premature blooming and consequent loss of vigour. For the strongest plants 6-inch pots should be provided, with the 5½-inch size for the moderate ones and the 5-inch for the weak growers. Crock with extreme care, and add some pieces of charcoal and half-inch bones above the crocks. The compost should consist of three parts best fibrous loam, two parts brown fibrous peat, one part sweet leaf-mould, one part coarse sand, a quarter of a part mortar rubbish

to a cold frame, as I find they are much less trouble.

Subsequent Treatment.—After the pots get fairly well filled with roots, gentle feeding must be systematically given. Clear liquid made from cow-manure and soot is excellent, but Ichthemic Guano is even better, used at the rate of a heaped tablespoonful to a gallon of rain-water and given twice a week. Both the above liquids may be given, but on alternate fortnights. After the flowers begin to open, an ordinary airy greenhouse suits them best, as the flowers will not only last longer, but the colours will be much more brilliant than if grown in a higher temperature. During the summer abundance of air must be given, and, indeed, at all times a close, stagnant atmosphere must be avoided. Strong heat at any time is disastrous. The chief enemies to the Cyclamen are green fly and the Begonia mite. Fortunately, good cultivation and an occasional vaporising with XL All will keep these pests at bay; but the Begonia mite is a most insidious foe, it can only be kept down in its early stages by constant fumigation. A good strain of seed should always be procured, as really fine varieties are just as easy to cultivate as the poor weedy things sometimes met with. Personally, I much prefer Sutton's Prize and Sutton's Giant strains.

Preston House, Linlithgow.

C. BLAIR.

aid. If, however, a central branch is staked upright, a new set of branches may be gradually formed. To prevent the branches of this class of tree becoming too dense, it is necessary to thin them out occasionally, while the effect of the tree is increased if the branches are kept free of the ground. Weeping trees of this class must have plenty of room to be seen to advantage, and it is a great mistake to plant them in very small gardens where they can never have a chance of developing properly. In this particular section two of the most vigorous examples are the Weeping Ash (*Fraxinus pendula*) and the Weeping Wych Elm (*Ulmus montana pendula*). The Weeping Holly (*Ilex Aquifolium pendula*), the Weeping Thorn (*Cratægus monogyna pendula*) and the Weeping Beech (*Fagus sylvatica pendula*) are also good. There are others, such as the Weeping Cherry and the Weeping Sophora, but they are less useful for general purposes.

For landscape effect the second group provides the best examples, for in this case the various trees attain a height approaching that of their respective types, while their varied habits are extremely graceful. To this group Young's Weeping Birch (*Betula alba pendula Youngii*), one of the most graceful of all weeping trees, belongs. Scarcely less elegant in outline is the ordinary Weeping Birch, which is frequently found wild in native woodlands, and sometimes comes true from seeds. The various Weeping Willows may also be included in this group, more especially *Salix babylonica*, *S. b. Salomonii*, *S. alba vitellina pendula* and *S. elegantissima*. The weeping kind of *Salix purpurea* forms a comparatively low tree or large bush, and although its wand-like branches are light and graceful, the general outline of the plant is less pleasing than the previously-mentioned kinds. There is also a weeping form of the Goat Willow (*S. caprea*), but it is hardly worth considering when making a selection. A Weeping Ash of this type is noticed in *Fraxinus Excelsior Wentworthii*, and a Beech in *Fagus sylvatica bornyensis*. *Ulmus glabra pendula* and *U. campestris microphylla pendula* are instances of decorative Elms with weeping secondary branches, while one form of *U. montana* has a similar habit. A singularly beautiful conifer with weeping branches is *Picea Morinda*, while *Cupressus nootkatensis pendula* and the various Larches are also of graceful outline.

The third group is typified by a Weeping Beech, which often assumes a commanding appearance. It is known by the varietal name of *miltonensis*. Another tree of similar outline is the weeping form of the White Mulberry (*Morus alba pendula*). In this case it is necessary to stake a leading shoot upright in order to get height into the tree.

It must not be assumed, however, that all weeping-habited trees are an acquisition to the garden, for such is not the case. Some have the appearance of monstrosities, and it would have been a good plan to have burnt them rather than have given them distinctive names and distributed them broadcast. Several pendulous forms of the common Spruce may be obtained, not one of which can be called ornamental. The same may be

said of the Weeping Apple, the Weeping Hemlock Spruce, one or two Weeping Plums and Cherries, although *Prunus pendula*, a good species, is really ornamental. In a few words, a really good weeping tree is a pleasure to look upon and a worthy occupant of the garden, but an inferior example is an eyesore and not worth the ground it stands upon; therefore select only the best kinds, and treat them to a liberal amount of good soil at planting-time in order to get all that is possible out of them. D.

THE FLOWER GARDEN.

SIDALCEA CANDIDA.

A NATIVE of New Mexico, *Sidalcea candida* is a hardy, handsome, herbaceous perennial, growing from 2 feet to 4 feet high and bearing terminal racemes of large pure white flowers. It is a very useful and ornamental plant for the herbaceous border, the wild garden or the shrubbery. At all times it should be planted in large masses; it then makes a very bold and attractive display. Even a bed of it in some secluded spot, providing

SIDALCEA CANDIDA, A USEFUL HARDY PLANT FOR BORDER OR WILD GARDEN.

it is not too shady, produces a very fine effect when in bloom.

Another species worthy of notice is *S. malvæflora*, from North-Western America, with lovely lilac flowers, which are not quite so large as *S. candida*. *S. Listeri*, of garden origin, has pretty pink flowers; this is considered by some authorities as a variety of *S. malvæflora*, but the flowers are not only of a different shade, but are larger and fringed, although that alone is not sufficient to make it a distinct species. They will all succeed in full sun or partial shade in any ordinary garden soil, and are easily propagated by seed or division of the roots, both of which should be carried out in the spring. F. G. P.

SWEET PEA NOTES.

The "National" Show.—It does not come within my province to give a report upon this magnificent gathering, but I feel that some slight reference is permissible in addition to the exhaustive details that have already appeared in the columns of THE GARDEN. In my last notes I deplored the fact that it had been decided to place baize-covered barriers down the middle of each table. I now most whole-heartedly condemn what was done. It was impossible to get a view of the charming general effect from any point of vantage save the gallery, and it is not possible to allow all and sundry to mount there to see the beauty of the show. Standing in the body of the hall or upon the steps of either annexe, one could see a single table and no more; whereas before these ugly boards were utilised one could see the length and breadth of the entire exhibition. The step is a retrograde one, and I hope that it will not be persisted in another season. If it is, I would suggest that each exhibit shall be penned off as is done at dog and poultry shows, since this is the only logical end of the matter. The object was to prevent the bunches on one side of the table clashing with and minimising the effect of those on the other side. But the serious clashing occurs when the bunches are side by side,

and the divisions ought, therefore, to come between them!

The Disqualifications.—I feared that double standards would prove to be somewhat of a curse to the judges, and such proved to be the case; but I was immensely relieved to find that my fear that Mr. Curtis would be promptly removed from this vale of tears was unfounded. When I reached the hall the secretary was alive and well, but suffering from an attack of depression which naturally followed the trouble into which he had been inadvertently driven. I had been judging Sweet Peas, equally as fine as the majority of those at the "National," at Wolverhampton with Mr. Fife of Dobbie's, and we were exceedingly careful

never to mention the words "double standards"—we had plenty of hard work to do without bothering about them. Many people will, perhaps, consider that the decision to disqualify any exhibit in which stems with double standard flowers are present is correct; but, personally, I am not of that opinion, and trust that the rule will have been rescinded before the next show comes along.

The Judges' Decisions.—In further relation to the rule that double standards should disqualify, I was greatly interested in the decisions arrived at by some of the judges. Going round the show, I found that in several instances the judges had decided that, as all the exhibits in a particular class contained flowers with double standards, they would judge the flowers on their merits. I maintain that they had no power to do anything of the sort. The exhibits contravened the rules of the society as printed and published, and

in this particular question, but it is impossible for me to overlook and fail to protest against the creation of a precedent which would, if persisted in, give the judges power to alter any rule in any schedule that might not meet with their personal approbation. The position is an impossible one.

HORACE J. WRIGHT.

FLOWERS IN AN OLD-FASHIONED GARDEN.

AMONG the many gardens scattered so freely throughout the Southern Counties of England, none are more pleasing than those attached to old-fashioned country houses, providing they have been allowed to retain their original features of simplicity and colour. Unfortunately, in many instances the owners or tenants of such houses are incapable of appreciating the quaint charms of such gardens, and instead of finding Box-edged

by Mrs. Sheaf, a lady who has for some years taken a very keen interest in the garden, and who has done much to retain its old-world character. On the June day when we were fortunate enough to visit this garden the air was filled with the scent of Madonna Lilies, Honeysuckle, Stocks and Box edging, all the paths having a bountiful margin of this old-fashioned shrub. The accompanying illustrations will give some idea of the character of the garden. The weathered red-brick retaining wall, with its venturesome Ivy, Sedums and other plants, seen in the first illustration, skirts the lawn, and the border above, as well as the one below, is filled, quite informally, with Roses, Madonna Lilies, Phloxes, Evening Primroses, Pinks, Japanese Windflowers, Stocks and similar plants. The second illustration represents a border lower down the garden, going towards the river that girts it at the bottom, filled with Chrysanthemum maximum, Cornflowers and Poppies, a simple yet beautiful combination that is quite in keeping with the surroundings. In the distance, and not visible in the illustration, are some ancient Filbert trees, planted doubtless by some village squire, and at the time of our visit these relics of bygone days were carrying the heaviest crop of Nuts we have ever seen. The peaceful aspect presented by the whole garden provides a delightful retreat from the bustle of modern life, and it will be a bad day for our country when such old-world gardens as this cease to exist.

WORK AMONG THE CHRYSANTHEMUMS.

THE work among the plants during this month is about the most important and interesting of any done throughout the season. It is important, because the majority of the precious buds must be secured, and interesting on account of the fact that the buds are the ones to develop into the magnificent blooms that cultivators strive to produce from December to the following November. Of course, experienced cultivators know all about bud "taking," but the beginner does not and is wishful to learn, so the following hints will be helpful to all such.

About Buds.—There are first-crown buds. These generally appear very early in August, and continue to do so, according to the variety, until the end of the month where the incurved section is included. The second-crown buds are those resulting from the due stopping of the plants in March and April in the first instance, and they mostly appear about the middle of August, and continue to do so until September 5 or thereabout. The terminal buds are those which appear later than any others, and the fully-developed flowers from such are generally only fit for exhibition in the case of a few varieties of the incurved section, but many of the single-flowered are good from such buds.

The Right Buds to Take.—"Taking" really means retaining. It is a term generally used among the cultivators of this plant, but "securing" or "retaining" would, either of them, be better words to use. However, the word "take" means

BRICK RETAINING WALL AND FLOWER-FILLED BORDERS IN AN OLD-FASHIONED GARDEN.

therefore they should have been instantly disqualified. I have been judging flowers, fruits and vegetables in all parts of the country for many years, and have always thought that the rules which governed the exhibitors also governed the judges. If this view is not correct, where on earth should we come to? To permit a judge or set of judges to alter the published rules is ridiculous, and would lead inevitably to endless confusion and dissatisfaction. And rightly so. Any prizes that were awarded at the "National" under the decision mentioned were illegal. Had the judges disqualified all the exhibits in a class, and then judged the flowers on their merits with a view to awarding special prizes, all would have been correct, provided, of course, that the committee had sanctioned it; but completely to ignore a rule was wrong, from whatever point of view one may regard it. I wish it to be clearly understood that all my sympathies are with the exhibitors

borders filled with flowers suitable for their surroundings, one too often encounters gaudy, formal patches of such kinds as bedding Geraniums and Calceolarias, excellent plants in their proper places, but totally unfitted for old-world surroundings. Thus, when we do find an old garden the owner of which has correctly hit the keynote of simplicity of arrangement and colour, it is all the more pleasing, and worthy of placing on record.

One such is the garden whence the illustrations (pages 390 and 391) were taken. This and the delightful old house known as The Park are situated at Stebbing, a typical Essex village some three miles north of the quaint little town of Dunmow, and skirting the Roman road that runs from Ware in Hertfordshire to Colchester in Essex. The history of the house does not now concern us, but that it occupies the site of a very ancient residence, the moat, with its surrounding moat that adjoins the garden, testifies. At present it is occupied

THE NEW
HOODED GLADIOLI
(Hybrids of *G. Primulinus*).

to retain a certain bud, and to remove all others or shoots surrounding them. In the case of all late varieties, such, for instance, as the Hon. Mrs. Lopes or Mrs. Gilbert Drabble, first-crown buds must be taken. If such buds appear very late in July, retain them, removing the side shoots near them one by one until all are removed. The work of "taking" may be spread over ten days. It is better to do this than to remove all unwanted buds or side shoots in one day; then the bud retained will receive no check, but continue to grow steadily and sturdily, and this is what we want. If the buds of very late-flowering varieties are taken about August 7, the resultant flowers will be practically perfect. Medium early varieties will show their buds from August 10 to August 25. If taken any time between those dates, the resultant flowers should develop just right. Very early-flowering varieties and the majority of the incurved section, as well as the single-flowered, should show their buds during the last week in August and the first week in September.

How to "Take" the Buds.—

The cultivator must watch the points of the shoots carefully every day and every evening, so as to destroy earwigs found there and to be ready to pinch out the young side shoots when the latter are about half an inch long, or just long enough to be quite free from the flower-bud. The latter must not be damaged in any way by the removal of the side shoots, and, as previously stated, the pinching out of these small shoots must be done gradually, one or two each day, until only the bud is left, the main stem and the main leaves on it. During the time the buds are being taken the plants should only receive clear water or occasional doses of very weak liquid manure. Directly the buds begin to swell freely, feeding may be resumed and a good top-dressing of rich compost put on.

AVON.

COLOURED PLATE.

PLATE 1452.

THE HOODED GLADIOLI.

THE coloured plate presented with this issue represents hybrid flowers of a particularly interesting character, viz., *Gladiolus primulinus*

crossed with varieties of *G. gandavensis* and *G. Childsii*. The hybridising of *Gladiolus primulinus* with other forms was taken in hand in this country and in America shortly after the species came into cultivation. It proved very productive as a parent, and, crossed with forms of *gandavensis* and *Childsii*, has produced a race midway in size and stature between the two parents, and the yellow colour of the type crossed with the stronger reds and pinks of the *gandavensis* has produced a number of intermediate soft shades of rosy apricot, pink, salmon and similar colours,

which are making the most delightful combinations. The hooded nature of *primulinus* is reproduced in varying degrees in the hybrids, which makes them most fascinating, both as plants in the border and especially for table decoration. They are all of easy culture, and Messrs. R. Wallace and Co., Kilnfield Gardens, Colchester, who kindly supplied the flowers from which the coloured plate was prepared, inform us that they have found them do well planted by the side of water, and also mention that evidently the liking for such conditions comes from the fact that *primulinus* is found growing in wet situations. The point

A SIMPLE BORDER OF CHRYSANTHEMUMS, CORNFLOWERS AND POPPIES.

worthy of notice is the fact that the majority of seedlings are all good and worth keeping, whereas in a general way seedlings of *gandavensis* do not produce all first-class flowers. Dr. Van Fleet, a well-known American authority on *Gladiolus*, has been working with these hybrids for some years, and has evolved a race which is superior in many respects to those previously introduced. *Gladiolus primulinus* is a native of Central and South Africa, the peculiar hood of the flower is said to be some protection against excessive moisture in the atmosphere.

THE ROCK AND WATER GARDEN.

YELLOW-FLOWERING CAMPANULAS.

THE colour of the Campanulas is generally more or less bluish lilac or white. The yellow-flowering ones are rare. In the chalk mountains of Central and South Europe one finds the Monocarpian (not bi-annual, as it is often said) *C. thyrsoidea*, which bears in May and June a dense thyrse of greenish yellow flowers, very fragrant. This is in common rock gardens; but two other species are seldom seen, which are yellow-flowering, too—I mean *C. petraea* and *C. velutina*. The first I found once in the neighbourhood of Puget-Thénic in the South of France. I had it many years ago in a wall, but could only once see its flowers. So I wished to see it in the wild state to note how it grows and to know how it must be raised. The plant was given as growing in the Escales d'Aiglun, in a very disagreeable slope of stones, where the sun shines with the deepest intensity. So we started at once, one of my sons, who was then living at Puget-Thénic, and I, in his lightest carriage, for the Escales d'Aiglun. But judge of my joy when I saw, just at the summit of the pass leading to the Valley d'Aiglun, in perpendicular and titanic walls close to the road, near a tunnel called Passe de Biolan, my yellow Campanula growing like weeds! It was not in flower, but no doubt that was it. It grew there in half-shady places in the leaf-mould accumulated by the centuries, in the crevices of the steep rocks, and was very flourishing. That plant has small yellow flowers, densely close together in short spikes, which flowers from August to October, and seldom ripens its seeds with us. Last year, of course, we got good and abundant seeds of it! The third yellow-flowering Campanula I have to speak of is *C. velutina* (*lanata*), which grows in the Balkans and in Asia Minor, and is often identified with *C. lanata*. Velenowsky, in his *Flora of Bulgaria* (page 365), does not hesitate to separate the two kinds, saying that while *lanata* is a bi-annual and has five stigmata

with a five-celled capsule, *C. velutina* is perennial, with three stigmata and a three-celled capsule. Then, in *lanata* the corolla is blue, but in *velutina* it is yellow. *C. velutina* grows very easily here in the crevices of my wall, in a sunny position, and sows itself between the rocks. It flowers in summer (July to October) in a pyramidal branch of yellow, rather big flowers, exceedingly picturesque to see. *Campanula mollis* of Spain, which is very near to the last, I do not know, and is, I fear, very rare in gardens.

Floraire, near Geneva.

H. CORREVON.

THE PAVED GARDEN.

HERE is at present a growing feeling among gardeners that the reaction against formality in gardening has reached its limit, and that it is time the pendulum began to swing back in the opposite direction. People are beginning to realise that gardening comprises something more than a servile imitation of Nature; that the artistic criterion of a garden is something higher than its naturalness. The mistake, which is still too often made, is the failure to realise the architectural character of such garden appendages as pergolas, trellises, arbours and summer-houses. With a growing appreciation of the fact that such things demand as careful planning as the dwelling-house itself there is arising a class of specialists whom one may

the undisturbed restfulness of long years, which should be an attribute of the paved garden.

If any plants at all be admitted upon the actual paving, the very greatest care should be exercised in their selection and insertion. It cannot too often be insisted upon that paving is primarily intended for the feet of man, and any plants allowed to grow upon the space devoted to that purpose must not only wear the semblance of having made a bold bid for freedom and escaped thither from the neighbouring borders, but they must in themselves be strictly in harmony with their surroundings. The indiscriminate planting of a variety of rock plants is most strongly to be condemned. To an artistic mind the result of such planting is as repellent as would be the appearance of casual foot-paths across one's choicest Rose-beds. As Rose-beds are intended for Roses, so are walks intended for walking upon, a proposition so elementary that its habitual neglect is little short of astounding.

A STONE GARDEN STAIRWAY OF BOLD DESIGN.

designate "garden architects." The particular branch of gardening to which we desire now to draw attention falls within the peculiar province of such garden architects, and a paved garden designed by one of that fraternity will be far less likely than would otherwise be the case to display such glaring and rudimentary errors as, for example, the use of so-called "rustic" work in conjunction with paved walks or courts. For one of the cardinal principles to be observed in the design and construction of the paved garden—be it merely a paved walk with or without a pergola, a paved Rose or water garden, or a paved forecourt—is that the only traces of rusticity allowable in such a garden are those due to art and not to accident. It is, for example, not merely permissible but desirable to encourage the mossing over of stone edgings and the interstices of paving, for thereby is obtained that venerable appearance betokening

A cardinal rule to be observed in planting crevices is that all traces of the gardener's hand must be studiously obliterated; accordingly, the most successful results are obtained where the paving is flanked by low retaining walls built of unmortared stones, the chinks between which are filled with suitable alpinas, so that any plants allowed to grow upon the paving appear to be favoured intruders in forbidden regions. Where no such retaining wall is present, it is advisable to have a stone edging covered here and there with the most prostrate plants, some of which may be permitted to trespass a short distance upon the walk. The varieties of *Phlox subulata* are peculiarly charming when grown in this way. Again, where the paths or walks are flanked by beds, in which the front portions are occupied by the lower-growing *Campanulas*, *Saxifrages*, or *Sedums*, a stray plant or two of the same variety may be allowed to wander

on to the adjoining pathway. But under no circumstances should these dainty rogues encroach beyond the outer edges of the paved walk. If the latter become so much overgrown that one has to pick one's way between tufts and clumps of plants which one would be loth to injure, then the bounds of moderation have been exceeded.

A solution of the difficulty is to be found in the use of exceedingly dwarf species only, such as the *Veronicas canescens* and *rupestris*, *Arenaria balearica*, *Herniaria glabra*, *Mentha Requienii*, *Thymus Serpyllum albus* and *coccineus*, and possibly also the *Acanas*, such as *inermis* or *pulchella*, or, best of all, *Buchanani*. None of these will resent an occasional trampling. Subject to the restrictions already stated, such dainty small flowers as *Asperula Gussonii* and *hirta*, *Campanula pusilla*, especially the variety named after Miss Willmott, and *pulla*, *Stansfieldii* and *waldsteiniana*; *Erinus alpinus*, *carmineus* and *albus*; *Hutchinsia alpina*, *Saxifraga muscoides atropurpureum* and *Rhei*, *Silene acaulis*, *Sedum farinosum*, *Semprevivum arachnoideum*, and such plants as the dwarf *Dianthus*, may be allowed upon the outer portions of the paving.

One of the most charming and effective uses of paving is in the Rose garden; but here, great though the temptation may be, the walks should be left free of vegetation, with the exception of moss. One word of warning should be given concerning the size of the stones employed. These should never be less than one foot square, but should preferably be considerably larger. For walks those of rectangular shape are most suitable. For a paved enclosed court, such as the little Tudor garden at Hampton Court Palace, stones of irregular sizes and shapes may be used. An admirable example of a large paved garden associated with tub plants and Lily tanks is to be seen in Kensington Gardens, near Lancaster Gate. Such a garden forms a most appropriate connecting link between the precincts of the house and those of the garden proper. Many alpinas will be found to seed freely between the joints of the paving; where there is ample space, a charming effect is produced by a few clumps of seedlings of plants such as *Campanula portenschlagiana*, *garganica* and *G. F. Wilson*; *Cheiranthus Allionii*, *Dianthus deltoideus roseus*, *Erinus alpinus*, *Linaria alpina* and *Papaver alpinum*. But even here the keynote of success is moderation.

RAYMOND E. NEGUS.

NOTES ON GARDEN DESIGN.

MANY a garden loses in attractiveness by the careless treatment of the short stairways which lead from one level to another. It is not always realised how much additional charm is given by the well-conceived design of such details, or how great a variety lies open to the straying choice. Steps need to be considered in relation to the retaining walls, in which they often make a break. They should have wide treads and narrow "risers" so that they are easy-going. Too great a regularity in their building is to be avoided. Rough rubble masonry is generally to be preferred to ashlar, where stone and not brick is the material, but the rustic character should not be overdone. Great variety is to be attained by a happy conjunction of straight with curved steps, as in the accompanying illustration, which shows also the value of rough piers to mark the break in the retaining wall. The example is chosen from Island, Steep, Petersfield, where is also the paved Rose parterre which was pictured in THE GARDEN last week. L. W.

GARDENING FOR BEGINNERS.

PROPAGATING BEDDING PLANTS.

THIS is very interesting work, and one in which amateurs take a great delight. Even the most experienced cultivators suffer some losses in the rooting of cuttings and in very favourable circumstances, so that the beginner must not be disheartened if he loses a few of the precious cuttings. When cuttings are taken in the spring, rather soft wood must be selected; but in the autumn young wood, well firmed, is the best, as very soft, sappy stems would be liable to decay either when first inserted in the soil or when the first dampness of the winter season came. Another guide for the benefit of the inexperienced may be given, namely, that the stems of cuttings which are to be rooted under quite cool conditions must be harder or firmer than those subjected to a gentle heat, especially a bottom-heat such as is provided by hot-beds or hot-water pipes under a propagating-frame.

Composts for Cuttings.—Two heaps of composts should be mixed, one being made up of fibrous loam and leaf-soil in equal proportions, with sufficient coarse sand added to render it very gritty in nature. Such a compost is grand for Zonal Pelargoniums, Petunias, Calceolarias, Gazanias and Marguerites. Another heap must be made up of fibrous loam, one part; leaf-soil, two parts; and sand, one part. In this case the compost will be suitable for Heliotropes, Iresines, Coleuses, Lantanas, Alternantheras, Mesembryanthemums, Ageratums and Fuchsias. As a general rule, at least three large leaves must be left on each cutting besides the small ones at the extreme point, after being duly prepared for insertion. All cuttings must have a heel to them—that is, a very small portion of the older wood attached—or be cut off just below a joint. The reason for this is that a callus forms more quickly and more surely than when the stem is severed between the joints, and consequently there are fewer losses. Cuttings may be inserted in pots, shallow pans, or in boxes about

1.—SECTIONS OF PREPARED POTS, WITH CUTTINGS IN COURSE OF PREPARATION.

four inches deep. Good drainage is essential. Some sand must be laid on the surface of the soil, as it prevents decay, and some sand must be borne down by the cutting-stick for the base of the cutting to rest on, as it conduces to the formation of roots.

The Best Time to Take Cuttings.—Zonal Pelargoniums, Fuchsias, Gazanias, Heliotropes, Ageratums and Lantanas should be propagated early in August; Mesembryanthemums and plants of a succulent nature generally during the latter part of this month; and other kinds of soft-wooded plants not of a true succulent nature during the early part of September. In their case a slight bottom-heat is advisable. Calceolarias are best

rooted in cold frames. Insert the cuttings at the end of September.

The Sketches Explained.—Fig. 1: The stem of a cutting as shown at A must be severed with a sharp knife just below a joint, and the lower leaf or leaves as shown at B. In the case of most kinds of cuttings, the lower leaves are best cut off; in that of Zonal Pelargoniums they are best when pulled off, and also all scales, as the latter often decay in the soil and cause the loss of the whole cutting. C shows how the crocking of a pot must be done; D, crocks; E, soil in the pot; F, sand on the surface. G shows the right kind of Heliotrope and a similar plant cutting—a basal shoot; H, the cutting prepared for insertion; I, stick to make the holes with. All flowers on cuttings must be removed. Fig. 2: J shows bottom of cutting-box, with holes and strips of wood to keep box off soil; Ja shows section of box prepared for the compost; K, cuttings in boxes in a frame; L, boxes on stage in a greenhouse; M, pots on side shelves; N N, pots on suspended shelves in a span-roofed house; O, sand round the base of a cutting; P, the callus formed prior to growth of roots. Water all cuttings when first inserted, then only when water is actually required. G. G.

HYDRANGEAS FROM CUTTINGS.

The common Hydrangea is justly admired for its large, showy heads of blossoms, and at this period, when many of them are at their best, one's thoughts naturally turn to their propagation. What is more, this is just the time to increase them by means of cuttings, which are not at all difficult to root, and the plants so obtained will, in many cases at least, flower next year. The best cuttings are furnished by the strongest unflowered shoots, such, in fact, as could be depended on to bloom next season if left on the plant. A length of 4 inches to 5 inches is very suitable for the cuttings, which should be cut off with a sharp knife just below a joint and have the bottom pair of leaves removed. H. P.

2.—HOW TO TREAT THE CUTTINGS AFTER PLANTING.

GARDENING OF THE WEEK.

FOR SOUTHERN GARDENS.

The Flower Garden.

Dahlias.—Give copious supplies of moisture at the roots. Earwigs are, especially in some localities, most troublesome, and should be trapped. The best method I know is to cut up some Broad Bean haulm, after it has been well ripened, into lengths of about six inches and tie these on to the stake, leaving a long piece of raffia so that the stem can be lodged in the foliage. Blow them out each morning into a bottle of water. Flowers intended for exhibition must be disbudded and sheltered from scorching sun and rains.

Anemones.—These are among the most gorgeous of our border plants, and continue to flower over a long period. Though some gardens and soils suit them better than others, a trial may well be afforded, especially of the St. Bridgid strain, which contain in the mixed varieties, literally speaking, all the colours of the rainbow. Select a piece of ground that is partially shaded, such as a strip in front of a trellis for hardy fruit, and draw a drill. Mix the seed with silver sand and sow thinly and evenly. Make the bed firm.

The Rock Garden.

Dianthus.—The various species on the rock garden may be increased by cuttings after the flowering period is over and as soon as the growths attain sufficient size. Hand-lights under a north wall or other shady position, and with a depth of 3 inches of sandy soil passed through a fine sieve, will suit the purpose. If the cuttings receive a good watering after insertion, occasional dampings overhead according to the weather will suffice until rooted. *Dianthus Napoleon III.* is a magnificent variety. The rich scarlet double flowers are freely produced, and have shown to great advantage near to a clump of *Thymus Serpyllum albus*.

Seed-pods.—Unless these are wanted to ripen for seed-sowing at a later date, they should be removed immediately the flowers are past, as, with the choicer plants especially, much of their vitality is absorbed, and the plants also present a much neater appearance.

Plants Under Glass.

Oleanders.—Where space permits for these to make bushy specimens, they rank among our most handsome greenhouse shrubs, and are at the time of writing making a grand display. There are several varietal hybrids of varying shades of colour. A plentiful supply of water will be needed when the plants become pot-bound, and liquid manure should be also afforded. When the flowers are past, the growths should be shortened back.

Winter-flowering Begonias.—Pot on the plants as becomes necessary, and attend to the staking and tying. Keep the surroundings moist to encourage a clean growth, and shade from bright sun. Plants of the *Gloire de Lorraine* type especially should have the flower-buds pinched out as soon as large enough.

Freesias.—Where the corms were saved from last year, they may now be shaken out of the old soil and graded according to their size ready for potting up shortly. No delay in sending the order early for these and the earliest-forced bulbs should be allowed, so that potting or boxing may be proceeded with and the receptacles may become well filled with roots.

The Hardy Fruit Garden.

Protection of Fruit.—At the time of writing many nests of wasps have been already destroyed. Choice fruits of Apples and Pears that are specially wanted without blemish should be protected with muslin bags. Where possible, much harm may be averted by covering the fruits with hexagonal netting, as we find that the birds commence by pecking the fruits and the wasps follow their mischief. Various traps should be hung near to the fruit, and bottles half filled with almost any kind of syrup will account for many, but to carefully hunt for nests and destroy them is the best means of eradication.

Early Apples.—Many of the early Apples may have their season increased by picking the most forward fruits carefully and placing them in boxes on a layer of wood-wool, storing in a warm cupboard and examining at intervals; or, better still,

they may be put on the hot-water pipes in a fairly dry house. As soon as sufficiently ripe, a dish may be selected in advance of those out of doors. This will detract but little from their flavour.

The Kitchen Garden.

Lettuce.—Make a good sowing now of Lettuce in drills in a sheltered part of the garden for late autumn and early winter supplies. A successional sowing or two made during the month will probably be found extremely useful for maintaining the supply. When the plants are large enough for thinning, the young ones that are removed may be transferred to positions where they will be less likely to suffer from early frosts.

Early Crops of Potatoes as soon as ready should be lifted, as nothing is gained by allowing them to remain in the ground, and, as I think I have already mentioned, no harm will result if the skins of the tubers do rub a little.

Seakale.—Keep this crop free from weeds by the frequent use of the hoe, and thin out the weak growths, also remove any flowering stems.

Brussels Sprouts.—Where time permits, the plants of these will benefit by having stout stakes placed to them, and any of the lower leaves that are decayed should be removed.

Fruits Under Glass.

Late Grapes.—Encourage the crop to swell freely by the application of stimulants to the borders. Look over the bunches carefully, and, if the berries are too crowded, cut out one or two where necessary, taking great care not to stab any of the others with the scissors. Ventilation must be carefully attended to. On hot days it is almost impossible to give too much air, and frequent dampings, leaving a good circulation on at night, will dispel condensed moisture and avoid much splitting of the berries. In the week ending July 20 we had a sudden change, when much less ventilation was needed and a slight circulation of heat in the pipes during the day as well as at night was welcomed.

E. BECKETT, V.M.H.

Aldenham House Gardens, Elstree, Herts.

FOR NORTHERN GARDENS.

The Flower Garden.

Spiræa Ulmaria.—This is one of the few handsome plants from which it would be a mistake to remove the old flower-spikes. After flowering they remain a nice brown colour for the remainder of the season, and are by no means only slightly decorative.

Climbing Roses.—Quite a number of these, e.g., *Dorothy Perkins* and its varieties, *Hiawatha*, *Crimson Rambler* and others, produce shoots from the base of the flower-trusses, which should all be removed. When left, they partially hide the bloom and are otherwise of no value. Continue to tie in the current year's shoots, which still are growing rapidly. *Banksian* Roses should have the growths secured by string and nail to walls.

Supporting Plants.—*Galtonias* are the better for a short stick to each, which steadies the spikes. Otherwise they are apt to straggle over in every direction. *Montbretia rosea* also needs partially supporting, several spikes being tied to one short and light stake. As a rule, other sorts need no support. Single-stemmed *Asters* sometimes require steadying, but as a rule I find these and many other plants which are usually staked stand well without supports.

Hedges.—Complete the trimming of all kinds of evergreen hedges as soon as possible. This work takes a lot of time where extensive, but by choosing weather when ground work is impossible the time is not so greatly regretted. Trees in the form of peacocks, pillars, cones, etc., should also be trimmed now, which leaves them neat till next year. In formal gardens, Box or other edgings should also be clipped, obvious irregularities being eyesores where these are concerned. Note, however, that variegated shrubs, Yews in particular, should be only very slightly trimmed at this time of year, else the variegation may be impaired for many months.

The Bog Garden.

Iris lævigata.—This is now the cynosure of this spot. I do not find it to succeed in the garden;

not that the plants do not grow, but in most years they fail to flower. When constantly wet during summer, they flower consistently. The blooms, if cut before expansion, are splendidly decorative.

Ferns.—*Osmunda regalis* succeeds well in the bog, and on its edge *Adiantum pedatum*, along with the *Cystopteris*, and *Asplenium Lonchitis*, usually difficult to grow, succeeds also a little raised above the water-line, and with these Bamboos associate and thrive.

Lilium pardalinum.—This fine Lily does not always succeed in light soils, but in the bog on a mound of clayey loam it grows with amazing vigour. Its season of flowering is again at hand, the long stems needing some slight means of support to preserve them in an upright position.

Indoor Fruits.

Wasps.—I never recollect so many hanging nests of wasps as have been found and destroyed this year. The assumption is that, being early at work nest-building, we shall have the fruit-eating brood also early. Nothing beats hexagonal netting nailed over the ventilators—the top ones only if the bottom ones are kept closed—as a preventive against wasps for all indoor crops. In very hot weather the glass should be shaded to keep the temperature from getting too high owing to the lessened ventilation.

Split Berries.—A few varieties of Grapes are apt to have more or less of the berries split at this season. Whenever a few are seen to be split, in however slight a manner, the shoot bearing the cluster should be notched halfway through an inch or 2 inches below the junction. Muscat berries sometimes drop, seemingly without any cause; but on a close examination this proceeds from the skin cracking quite close to the place of junction of the berry with the petiole. Try the like means as a precaution.

Frame Melons.—These ripen well during the next six weeks by giving attention to ventilation so that the temperature in the daytime is high, and by means of coverings kept from falling low during the night. Expose the ripening fruits by raising them close to the glass. The fruits keep in good condition for a long time if preserved in a cool room.

The Plant-Houses.

Cinerarias.—These should be advanced enough to transfer from boxes to 4-inch pots. They grow rapidly in a rough compost made moderately firm, and after a few days' protection from the weather should be exposed night and day. Coolness is very important, and a platform of hard coal cinders, always kept moist, suits them well and is a certain means of preventing the attack of green fly.

Begonia Gloire de Lorraine.—The most forward of these are now ready to be staked out, using for the purpose extremely thin sliced Bamboo.

Begonia Gloire de Sceaux.—This is almost as useful as the last-named, and the plants may now be finally shifted into their flowering pots. It depends on the size of the material wanted what pots should be used. Very nice plants can be produced in 7-inch pots, and they can be shifted from small pots to large ones successfully. Rough rotted turf and dried cow-manure rubbed through a fine sieve suits them well. It is essential to have the foliage large and well-coloured, and only by keeping the plants growing freely and without the slightest check can this be attained.

The Vegetable Garden.

Spinach.—Where this vegetable is in request during winter, a large breadth should be sown in the course of a few days, choosing one of the broad-leaved varieties, which give much the best results. It usually succeeds some earlier crop, and the ground, as a rule, needs to be merely loosened with a fork to make it ready. In dry weather soak the drills with water previous to sowing the seeds, and use comparatively very few of these.

Celery.—A sufficient quantity for autumn use may be completely earthed up at any suitable opportunity. It is best done shortly subsequent to a heavy rainfall, or else in dry weather the day after artificially flooding the trenches. The stalks must be tied previous to applying soil, and instead of fastening the ligatures with a double knot, one is sufficient, provided it is turned twice instead of once.

R. P. BROTHIERSTON.

Tyninghame, Prestonkirk, N.B.

ANSWERS TO CORRESPONDENTS.

RULES FOR CORRESPONDENTS.

QUESTIONS AND ANSWERS.—The Editor intends to make THE GARDEN helpful to all readers who desire assistance, no matter what the branch of gardening may be, and with that object will make a special feature of the "Answers to Correspondents" columns. All communications should be clearly and concisely written on one side of the paper only, and addressed to the EDITOR OF THE GARDEN, 20, Tavistock Street, Covent Garden, London, W.C. The name and address of the sender are required in addition to any designation he may desire to be used in the paper. When more than one query is sent, each should be on a separate piece of paper. Plants for naming should be clearly numbered and securely packed in damp grass or moss, not cotton-wool, and flowering shoots, where possible, should be sent. It is useless to send small scraps that are not characteristic of the plant. Letters on business should be sent to the PUBLISHER.

FLOWER GARDEN.

ALOES (D. H. P. Dennis).—We presume that by Aloes you mean *Agave americana*, which is often called the American Aloe. If that is so, it is unlikely that you will be able to keep the plants out of doors throughout the winter without running the risk of having them seriously injured or killed outright. In the event of severe frost occurring, you could erect a covering of mats around them, and so give them some protection; but, except in the extreme South-West of the country, we advise placing such plants under cover for the winter months. You may rebud them at once. Take good, coarse, fibrous loam, three parts, and mix with it one part of pieces of sandstone and mortar rubble. You may also add a fair quantity of half-inch bones. Drain the new tubs well, and make the new soil very firm about the old balls.

SPARAXIS, HABRANTHUS AND LITHOSPERMUM (Collapit, Devon).—The Sparaxis might be safely transplanted early in September. The plant dislikes much lime, and luxuriates in moist and very sandy soils or a mixture of loam, peat, leaf-soil and sand in equal parts. A good depth of this and full moisture during growth should be assured. Bury the roots 4 inches or so below ground-level. In the case of severe frost, the bed should be mulched with light manure. The Habranthus prefers a bed of very sandy loam, well drained and about eighteen inches in depth. Lift and replant a few weeks after the bulbs have fully matured and the leafage has died down. Replant 5 inches deep. The Lithospermum are best propagated from cuttings inserted during August and September in a hand-light or frame placed in a rather shady spot. The soil should be made very sandy. The best cuttings are non-flowering shoots an inch or more long. These are best secured by cutting back the old flowering stems—these stems are practically useless for propagating—and with new growths appearing of the size indicated, strip them off with a heel attached and insert without more ado. With care in watering, the majority of such cuttings root quite well.

MADONNA LILIES AND WIREWORM (Mrs. M. M. G.).—There are several so-called soil fumigants that are supposed to kill this pest, though opinions vary considerably as to the fact, and our own experiences of some of them are not of a convincing nature. We know full well the trouble this pest is to growers of Lilies, Gladioli and other things; hence a perfect and always reliable remedy that would not inflict injury upon plant-life nor have a paralyzing effect upon the soil would be a boon to all. The old remedy of gas-lime is still good where large areas have to be treated, though in the garden we think you cannot do better than try Apertite, now being advertised in our columns. A difficulty in your case would be that you could only treat the soil near where you desire to plant, and even though the pest be eradicated from that small area, it might be attracted to its food from other parts. The wireworm at this time of year works very near the surface, and light forking and hand-picking would get rid of many. You might also endeavour to attract them by means of Carrot or Potato traps sunk in the soil, arranging a few 1 foot or more from the groups of Lilies, and examining them from time to time. In the same way other parts of the border may be treated. The soil treated with fumigant would be ready for planting about ten days after the application. As your Lilies are in pots, there is no immediate hurry for planting them.

THE GREENHOUSE.

BEGONIA MITE (W. A.).—Your Begonias are badly attacked by the Begonia mite, to destroy which you must dip the plants in one of the many nicotine preparations, or vaporise with the XL All Vaporiser. In either case one application will not be sufficient, as two or three at intervals of a few days or a week will be required in order to make matters safe.

HELIOTROPE (W. S. S.).—Cuttings may be rooted in August and September, and the young plants kept in store pots for the winter, potted separately in February, and grown on to plant out of doors in June or to flower in the greenhouse. For the latter work, batches are brought

on to flower at intervals. This can be accomplished by rooting cuttings at various times and by attention to stopping. To our mind, Sweet Peas look best when each kind is kept distinct, although that is purely a matter of individual taste, some people preferring them mixed. In either case they are very pretty. Seeds of *Salpiglossis grandiflora* should be sown out of doors towards the end of March to bloom in July, or the seed may be sown indoors in boxes and the seedlings transferred to the open in May. A sunny position and good loamy soil with plenty of water are essentials to success. The plants ought to be at least 9 inches apart each way.

PRIMULA SIEBOLDII (E. P.).—This Primula is best treated as a pot plant, although good results are achieved when grown in beds or masses in the open ground, but partial shade is necessary. There appears to be nothing wrong with your plants. They usually commence to grow in the spring, and about April produce a good crop of flower-spikes, after which the plants gradually die down for a month or two. Occasionally a second lot of leaves and spikes appear, but not in such profusion as earlier in the year, when the plants go to rest for the winter months. Repotting takes place about February, and when root action is well advanced they need plenty of water till the foliage shows signs of decay, but even then the base must not be allowed to become dust dry. The creeping roots, or "stolons," may be taken off and potted up if it is desired to increase the stock. If your plants do not produce any flower-scapes, the cause is probably due to watering, or they may not be quite strong enough.

TREES AND SHRUBS.

MYRTLE (M. M.).—From the appearance of the Myrtle shoots sent for examination, we imagine that the plant either is, or has been, short of water. Although you may have given the plant, as you thought, plenty of water, it may have run round instead of soaking into the soil, a condition which often occurs when plants have been placed in borders after having been for a long period in pots. You cannot do better than uncover a portion of the old ball and examine it carefully. If it appears to be dry in the centre, place a rim of clay round the margin of the ball, and keep the basin formed filled with water until the soil is thoroughly soaked. Retain the basin for a few months for watering purposes. The plant is not likely to require feeding in the present state.

ROSE GARDEN.

FOLIAGE BLIGHTED (H. O.).—The foliage sent shows all the signs of injury by a very late frost, but the brown patches are the result of the Rose slugworm, a little pest very much about this year, and you will see recent remarks as to this pest in answer to other correspondents. We should say from the appearance of the small foliage that you did not prune your Roses sufficiently, for all of the varieties you name should have foliage twice the size of that you send; or perhaps the soil needs some good fertiliser, for the autumnal dressing of manure may not have been sufficient. If one expects good Roses, one must feed the plants, and when they are strong and healthy they can better resist these diseases and pests.

THE CHEROKEE ROSE (F. A. S.).—As you say that the American Cherokee Rose to which you refer bears white flowers, it is quite likely that it is the true Cherokee Rose of China, for some authorities say that the Cherokee Rose (*Rosa levigata*, sometimes called *R. sinica*) is naturalised in the West Indies and in some parts of the Southern States of North America. It was introduced to English gardens in 1759, and probably found its way to the United States at an early date. If a specimen of the Rose could be sent, we should have no difficulty in identifying it. One distinct character is its evergreen, three-parted leaves. The plant was at one time named *Rosa cherokeensis*.

ROSES FOR SHADY POSITION (A. G.).—We should advise you to remove some of the old growths from the pergola. There is nothing gained in allowing Rambler Roses to smother other plants or usurp too much space; indeed, the blooming is usually much finer when old growths are removed. The best time to do this is in August, when the flowers have fallen. For the shady border to produce a good blaze of colour, we would suggest Polyantha and Monthly Roses, planting several plants of a sort 1 foot apart each way. Good kinds are Orleans, Jessie, Katherine Zeimet and Mrs. Cutbush among Polyanthas, and Old Crimson China, Fabvier, Leuchteuer, Crimson Pink and White Pet. Some of the lovely Tufted Pansies will grow well in a partially-shaded border, so also will the many brilliant-coloured forms of *Phlox decussata*.

FRUIT GARDEN.

KEEPING PEARS AND APPLES (J. C. Le S.).—We are sorry we cannot throw any effective light on the very interesting question asked by a correspondent. We repeat the question here in the hope that some of our readers may be able to do so: "Could you give me the best methods for keeping fruit, such as Pears and Apples? I know there are many and various kinds of store-rooms, but even with the best of these one cannot keep fruit long. What I would like to know is, if one could devise a plan whereby fruit would be put in large tin vessels and the air pumped out, if the fruit would keep in that manner, say, for six or eight months. I know all about the system of preserving through canning; but, of course, this is heated in order to get the air out. The question, therefore, is: Would fruit keep any time in what is known as empty space, or, I should say, where the air is not?" A large number of

late-keeping Pears and Apples have been added to our collections of late years, so that the urgency of this process is not so greatly felt as it used to be.

NECTARINES AND PEACHES (Bruce).—We have little doubt but that the Nectarines are suffering from skin scorching by hot sun gleams, probably in the early morning when the house was insufficiently ventilated. It is a common occurrence in hot weather, especially in the case of the Nectarine, but seldom so with the Peach. The cause of the Peaches splitting we would attribute to a heavy watering, followed by a hot day and an insufficiency of ventilation. It is better to water in the evening, especially when the fruit is approaching the ripening period, admitting air freely.

GRAPES DISEASED (H. S.).—Your Grapes are suffering from the effects of a disease termed "scalding." It invariably attacks the Grapes about the time the berries are nearly at their full size and when they begin to colour. It is caused by a too cold, close and sluggish atmosphere, especially at night. The way to arrest its further progress and to prevent an attack next year is to ventilate theinery freely front and back at this stage of the Vine's growth, both day and night. Should the weather turn cold at night, have a little heat in the hot-water pipes. This will prevent the temperature falling too low, as well as assist the free circulation of air and so prevent a sluggish atmosphere.

PLANTING APPLE AND PEAR TREES (R. T.).—Apples, we think, would pay you better than Pears. The bush form of trees for Apples, and the pyramid for Pears would, we think, be the best. The Apples should be worked on the broad-leaved English Paradise stock, and the Pears on the Quince. If the ground can be trenched before planting, the progress of the trees afterwards will prove much more satisfactory, and the ground between them may be planted with Strawberries or Gooseberries without any harm being done, so long as they are not planted too near the stems of the trees. On no account must grass be permitted over the roots of the trees. We presume that you wish to grow for sale, and not for home consumption. We therefore give a list of varieties suitable for your purpose: Apples, dessert varieties.—Devonshire Quarrenden (early), Worcester Pearmain (early), James Grieve (September and October), Ellison's Orange (September and October), Cox's Orange Pippin (October to Christmas), King of the Pippins (November to Christmas), Allington Pippin (November to Christmas), Christmas Pearmain (November to January), Barnack Beauty (January to February), Sturmer Pippin (February to May), Apples, cooking varieties.—Potts' Seedling (August to September), Grenadier (October), Lord Derby (November and December), Warner's King (November and February), Annie Elizabeth (January and February), Newton Wonder (February to May), Bramley's Seedling (February to May), Sandringham (February to May), Pears, dessert varieties.—Beacon (very early August), Fertility (September), Hesse (September), Marie Louise (October), Williams' Bon Chrétien (October), Emile d'Heyst (November), Doyenné du Comice (November), Bielding (January to February), Le Lectier (January to February).

KITCHEN GARDEN.

TOMATOES (G. W. B.).—The Tomatoes appear to lack a sufficiency of potash. Water the plants now with a solution of half an ounce of sulphate of potash in two gallons of water.

CELERY BOTANICALLY (J. D.).—From all botanical, as well as from all cultural, points of view, Celery (*Apium graveolens*) is a biennial. If sown very early under glass, the plants grown on strong and rapidly, it often assumes an annual character, as it is sometimes common to find otherwise fine blanched stems in the autumn to have begun inside to send out flower-stems. If Celery be planted out in quantity for seed production, the plants not being blanched, they all bolt to flower the following summer. However, it may be possible to change the nature of Celery, were plants growing in the open ground now blanched and the leaves kept rather hard picked for soup flavouring; also, if flower-stems broke, these were picked out. It is quite possible in such case that the whole nature of the plant might be changed, but we have had no experience of it. Is the writer you refer to really worth powder and shot?

CABBAGES (L. W. S.).—Your Cabbages, &c., are attacked by the Cabbage-root maggot. This is the grub of a blackish, two-winged fly, rather similar in appearance to the house-fly. It lays its eggs near the Cabbage root, and sometimes upon it, in May or June, and the grubs pupate in the soil, turning to flies after a short time, there being about three, perhaps four, broods during the year. The pest is extremely difficult to deal with, and seems particularly abundant and troublesome this year. Some success has attended watering along the rows with an emulsion of carbolic acid made by dissolving 1 lb. of hard soap in one gallon of boiling water to which is added one pint of carbolic acid, the whole being churned with a syringe until thoroughly emulsified, and then diluted with twenty times its bulk of water. Care should be taken not to touch the plants when watering. Nitrate of soda will sometimes prevent the flies from laying their eggs, and the American growers put a piece of card close on the soil round the plants so as to prevent the fly getting near.

MISCELLANEOUS.

FUNGI (M. D.).—You would probably find the best book with plates of British fungi is "Cooke's Illustrations," which may be purchased for about £12 or £13. Cheaper books with coloured plates are published from time to time, but it is very difficult to get the colours true.

Routledge have recently published one containing figures of many and descriptions of most of the larger fungi. You will find full descriptions in "Masse's Fungus Flora" and W. G. Smith's "British Fungi" (published by the British Museum). Your fungi are apparently (a) *Russula cyanosantha*, not *A. heterophyllus*; (b) *Amanita rubescens*; (c) *Polyporus squamosus*. Badham's is the best book on edible fungi; but you, as a medical man, will recognise that not all people are affected in the same way by fungi.

NAMES OF PLANTS.—*Columel E. P. B. S.*—The Roses are: 1, Marie van Houtte; 2, Souvenir de Pierre Notting; 3, Pride of Waltham; 4, Comtesse F. Hamilton. —*G. H. Sheffield.*—1, Petals fallen; 2, Fisher Hohnes; 3, Prince C. de Kohau; 4, Caroline Testout. —*H. U. Hyde Park.*—1, *Ulmus campestris viminalis aurea*. —*Ignoramus.*—1, *Sedum stoloniferum*; 2, *Sedum spurnum*; 3, *Tunica prolifera* (not rare). —*R. A. Dumfriesshire.*—1, *Spiraea canescens*; 2, *Geranium Endressi*; 3, *Philadelphus microphyllus*; 4, *Poterium canadense*; 5, *Cassinia fulvida*; 6, *Stachys Betonica* (Wood Betony); 7, *Berberis vulgaris* (Barberry); 8, *Lonicera alpigena*; 9, *Sutherlandia frutescens*. —*E. M. Parkstone.*—1, *Rhus Cotinus* (Venetian Sumach). —*G. W. G. Yorks.*—1, *Sidalcea listeri*. —*Neelans.*—1, *Michauxia campanuloides*. —*P. H., Airdrie.*—1, *Ceptherra glauca*; 2, *Sidalcea candida*; 3, *Centaurea montana*; 4, *Lycchnis dioica flore pleno*; 5, *Dicentra formosa*; 6, *Geranium sanguineum* (Bloody Crane's-bill); 7, *Poterium canadense*; 8, *Spiraea Menziesii*. —*P. A. S., Wrexham.*—1, *Gemista tinctoria* (Dyer's Green-wood); 2, *Dianthus deltoides* (Maiden Pink). —*M. M. F.*—1, *Six inches*, *Oxalis floribunda*; 1 foot, *Linum grandiflorum* 2 feet. (Another *amena flore pleno* (Godetia)). —*A. T. U.*—1, Carnation, crimson self, Nox; 2, seedling, ragged rose self; 3, seedling, white-ground Picotee, heavy purple edge ground not clean; 4, seedling fancy.

SOCIETIES.

NATIONAL CARNATION AND PICOTEE SOCIETY.

The annual exhibition of the southern section of this Society was held at the Royal Horticultural Hall, Vincent Square, Westminster, on July 23. By a general consensus of opinion the quality of the blooms was decidedly good, although amateurs in Southern Counties would have done better had the show been ten days earlier. There were numerous non-competitive groups, chiefly of herbaceous plants, which brightened the hall and helped to relieve the inevitable monotony of show-boards and vases. In the early part of the afternoon the attendance was meagre, but later on visitors came to the hall in good numbers.

FIRST DIVISION.

For a stand of twelve blooms on cards, bizarres and flakes, Mr. C. F. Thurstan of Wolverhampton led the way, closely followed by Mr. J. Douglas, Great Bookham, and Mr. H. Mathias, Medstead, Hants. The varieties Flamingo, Ophelia and Gordon Lewis were well represented.

In the class for twelve selfs, shown on cards, Mr. Mathias was first with a splendid stand, including a dressed flower of Mand Allen, which was awarded a special prize as the premier self Carnation. Mr. Thurstan was second and Mr. J. Douglas third.

Mr. Mathias was again successful in a stand of twelve fancies. A beautiful bloom of Becky Sharp was awarded the special prize as the premier fancy Carnation. Messrs. Thurstan and Douglas followed in the order named.

Messrs. A. R. Brown, Limited, King's Norton, were first for twelve Picotees, white ground; Mr. J. Douglas second, the latter showing a capital bloom of Amy Robsart, the premier heavy-edged white-ground Picotee in the show.

For twelve Picotees, yellow ground, Mr. H. Mathias was first with a perfect stand in colour and quality. Mr. J. Douglas' second-prize stand contained a dainty bloom of Mrs. J. J. Keen, awarded the special prize as the premier heavy-edged yellow-ground Picotee.

Mr. J. Douglas was an easy winner for four selfs in vases, showing Bob Aeres, Daffodil (of exceptional size), Mrs. G. Marshall and Mrs. G. Jones. It was an excellent exhibit, and aided the exhibitor in securing the silver cup given to the winner of the highest aggregate number of points gained in the first division.

Mr. Douglas was again successful for four fancies in vases, his vases of Pasquin and Lord Steyne being much admired. The same exhibitor was first for four white-ground fancies. The variety The Bride was in great form. He was again first for four Picotees, yellow ground. In the last-named class Mrs. J. J. Keen was one of the best varieties shown.

A good deal of enthusiasm was centred around the class for nine distinct selfs, fancies and yellow-ground Picotees. Mr. Douglas was first with a superb collection, followed by Mr. Mathias and Messrs. A. R. Brown, Limited. We were much impressed with the excellence of the blooms of Linkman shown in the first two collections.

SECOND DIVISION.

Three lovely blooms of Lady Hermione enabled Mr. D. Walker of Kilmarock to carry off the premier award for a vase of pink or rose self varieties.

Mr. R. Morton, Woodside Park, was first in a similar class for whites with first-rate blooms of Mrs. Eric Hambro; and again for dark red or maroon selfs with Mrs. George Marshall.

Mr. Morton was again to the fore in a well-contested class for a vase of yellow selfs. The variety Daffodil was much in evidence in this class.

For three blooms of red or scarlet selfs, Mr. W. H. Parton, Moseley, was first, followed by Messrs. Walker and Morton.

Mr. R. Morton was once more successful in the class for a vase of yellow-ground Picotees, showing Exquisite in fine form; and again for buff or terra-cotta selfs with lovely blooms of Elizabeth Shiffner.

Mr. G. D. Ford, Aceck's Green, was first for yellow or buff ground fancies with exquisite blooms of Mrs. Penton; and Mr. W. H. Parton led the way for three fancies other than yellow, buff or white ground with the vivid pink J. Sebright.

There was very keen competition in the class for six selfs, fancies and yellow-ground Picotees, and that successful exhibitor Mr. R. Morton again took premier honours. Mr. W. H. Parton was a good second, and Mr. E. J. Price, Bourneville, was a creditable third.

The dressed blooms shown on boards, each with a white paper collar, still attract much attention, especially from those who admire the Carnation solely as a florist's flower. Mr. H. R. Taylor of Cheam and the Rev. C. A. Gottwaltz were notable winners in this section.

The Martin Smith Memorial Challenge Cup, open to amateurs only, was won by Mr. Robert Morton.

The premier award for table decorations was won by Mr. E. J. Price, Bourneville.

THIRD DIVISION.

This division is set aside for those who do not grow more than 300 plants in pots and do not employ a gardener regularly nor advertise plants for sale. The quality of the blooms in this section was remarkably good, and we much regret that pressure on our space prevents us from giving a detailed report.

Mr. J. B. Willett of Yardley was first for six selfs, showing first-rate blooms of Sir Galahad and Elizabeth Shiffner.

Mr. Willett was again successful for six fancies, followed by a highly creditable exhibit from Mr. E. C. Chambers, Wellingborough.

OPEN CLASSES.

Some of the very best blooms in the show were to be seen in the open classes. Mr. Douglas was a prominent exhibitor, gaining first prizes with excellent vases of Bob Aeres, Rosy Morn, Daffodil, Mrs. G. Jones and others. The Cartwright Challenge Cup and a silver-gilt medal were won by Mr. Douglas for the excellence of his exhibits in the open classes.

Mr. H. Mathias was successful in the class for nine white blooms, showing Titan in unrivalled form and purity.

Mr. Lakeman, who also showed a magnificent non-competitive group of Carnations, gained the first place for nine dark red or maroon selfs showing the well-known variety Mrs. George Marshall.

HASLEMERE HORTICULTURAL SOCIETY.

The forty-second annual show of this society was held in the grounds of Whitwell Hatch, Haslemere, the residence of Earl Altamont, on Wednesday, July 24. The glorious natural surroundings of the place made the occasion a delightful change, especially after the dingy setting of some of the larger shows. The entries were numerous, the quality of the exhibits decidedly good, and the attendance was satisfactory. There were a few good non-competitive exhibits. Messrs. G. Jackman, Woking, staged a collection of Roses in good condition. They also put up a few hardy perennials. The Guildford Hardy Plant Nursery had a stand of perennials, including herbaceous Phloxes and many other good things. Messrs. Maurice Young and Sons, Milford Nurseries, also staged perennials and a few Roses, as did Messrs. Gauntlett. The amateurs' and cottagers' sections were filled to overflowing with capital produce, and it would be invidious to single out any individual exhibitor for special praise. The children's classes were interesting, and other societies might take a lesson from Haslemere. Collections of mosses, wild flowers and pressed specimens were well staged, and betokened infinite care on the part of the little exhibitors, and when they (the prize-winners were mostly boys) received their prizes from Countess Cawdor, their smart military salute was delightful to behold. The band of the Royal Engineers (Aldershot) on the tennis lawn and the morris dancing by the village school-children helped to impart a fairy-like aspect to a most enjoyable show.

BRIGHTON AND SUSSEX ROSE AND SWEET PEA SHOW.

The twenty-first annual exhibition was held at the Dome and Corn Exchange on July 23 and 24. This date, unfortunately, proved too late for many, who perforce were compelled to cancel their entries, especially in the Rose classes. The trade, however, made up for the deficiency. Specially attractive was an arrangement of ornamental plants—stove and greenhouse—by Messrs. Balchin and Son, Brighton, as also the lengthy staging of rare and choice vegetables, Melons, &c., tastefully interspersed with hardy and other choice flowers, displayed by Messrs. Sutton and Sons, Reading, both exhibits receiving an award of a gold medal. Another remarkable display was that of Carnations from the Clury Nurseries, Laogley, Bucks, which evoked general admiration and many regrets that the committee had not bestowed upon it a

higher award than a silver-gilt medal. Other recipients of the same class of medal were: Mr. G. W. Piper, Uckfield, for Roses; Messrs. Wells and Co., Mersham, a brilliant display of Phloxes and Carnations; Barnham Nurseries, Limited, Roses and choice herbaceous flowers; Mr. Frank Woollard, Brighton, Roses. Silver medals were awarded to Messrs. Blackmore and Langdon, Bath, for a striking display of Begonias; Messrs. Cheal and Sons, Crawley, Sweet Peas and miscellaneous hardy flowers; Messrs. George Miles and Sons, Mr. James Davies, and Messrs. Tilley and Sons, Brighton, horticultural sundries; and Messrs. Peters, Brighton, beautifully-displayed floral designs.

COMPETITIVE CLASSES.

In the open classes for plants, Mr. Frank Woollard secured the handsome silver cup, the society's silver medal and first prize for a group of Roses, either plants or plants and cut blooms.

Miscellaneous group of flowering and foliage plants arranged for effect in a circle 10 feet in diameter: First and silver medal, Mr. Charles Moppett, jun.

Mr. George Chandler led for a table of flowering and foliage plants, followed by Messrs. George Miles and Son and Mr. Charles Moppett, jun., in the order named. Mr. Chandler was successful in the class for a circular group of miscellaneous flowering and foliage plants, winning outright the handsome silver cup offered in this class. The Corporation's Challenge Bowl, offered for retention for one year to the most meritorious exhibit in the show, was awarded to this group.

In the cut-bloom class, Mr. Frank Woollard was the most successful competitor, scoring for thirty-six cut blooms of Roses, distinct, and also for twenty-four blooms, distinct. Mr. W. R. Hammond was first for twelve blooms, distinct, followed by Mr. E. W. Morris, Uckfield. In the classes for eighteen blooms, Teas or Noisettes, and twenty-five long-stemmed Roses, Mr. Frank Woollard again led.

SWEET PEAS.

Twenty-four sorts in twenty-four vases, twenty stems of each: First and silver medal, Mr. W. R. Hammond, Burgess Hill; second, Mr. H. MacFadyen, Cuckfield Park; third, Mr. C. Marshall.

For twelve sorts in twelve vases, Mr. W. H. Smith led, with Mr. G. Pilgrim second and Mr. W. G. Pelley third.

For thirty stems of white, Mr. Samuel Watkins was first with Etta Dyke; second, Mr. W. H. Smith; third, Mr. A. Sayers.

Thirty stems of pink: Mr. W. H. Smith was first with excellent sprays of Hercules; second, Mr. A. Jewell; third, Mr. J. Martin.

Thirty stems of blue or mauve: Mr. A. Jewell came first with Flora Norton Spencer; second, Mr. H. MacFadyen; third, Mr. W. H. Smith.

Thirty stems of crimson or scarlet: Mr. A. Jewell again led with Maud Holmes, followed by Mr. W. H. Smith and Mr. G. H. Bennett third.

Six vases of Carnations, eighteen blooms in each vase: The society's silver medal and first prize fell to the Clury Nurseries, with lovely blooms of Mikado, Fair Maid, White Perfection, Winsor, Mrs. C. W. Ward and Lawson Enchantress. Mr. G. Eastwood, Hassocks, was second.

EAST ANGLIAN HORTICULTURAL CLUB.

OVER one hundred members and friends joined in the summer excursion of this club to the noted gardens at Westwick House, Norwich. Colonel Petre, through his genial gardener, Mr. George Davison, had thrown the whole of the gardens, woods and fruit farm open for the party to ramble at their own will. The day was rather cooler than the previous few days, which was much to be thankful for. Almost as soon as the visitors entered the gardens they were passing under a huge pergola over three hundred feet long, and covered with all the choice subjects associated with such locations. The varieties of Vitis were most numerous, and gave a charming effect. A little further, and the visitor was passing along a herbaceous border over three hundred and fifty feet in length and at no part less than 30 feet wide. The subjects here are planted in large bold masses, and to see them in their glory is a sight to be remembered. Most hardy plant growers know what Mr. Davison has done to improve the Montbretia, and it was not to be wondered at that huge tracts of the garden are planted with this flower. We saw some plants not yet in commerce, bold in foliage and pictures of health. Everything in the greenhouses and vineries seems thriving at its best, pointing all along to the skill of the man in charge. Fruit-growers, and especially those who have visited the autumn shows of the Royal Horticultural Society for British fruit, know of Mr. Davison's skill in the culture of Pears. To see his trees is an education. This year they are better than ever, and we shall not be surprised to hear that important prizes are won with fruit from them this year. Apples, too, are looking in first-class condition. After the mansion garden had been thoroughly inspected, the party, under the escort of Mr. Davison, wended their way to the fruit farm, in which Colonel Petre has taken great interest. Tons of Black Currants had just been gathered and sent away, and the pickers were busy upon the Raspberries. All these pickers are local people, and the money they are able to earn in this work is a great benefit to the local community. The woodlands, noted for their many kinds of timber, especially Firs, were not forgotten, and the large lakes added a charm to the whole of the sylvan scene. Much more could be said, but one must not encroach on the space further. Suffice it to say that everyone interested themselves and were well pleased with the visit.

EDITORIAL NOTICES.

Every department of horticulture is represented in **THE GARDEN**, and the Editor invites readers to send in questions relating to matters upon which they wish expert advice.

The Editor welcomes photographs, articles and notes, but he will not be responsible for their safe return. All reasonable care, however, will be taken, and where stamps are enclosed, he will endeavour to return non-accepted contributions.

As regards photographs, if payment be desired, the Editor asks that the price required for reproduction be plainly stated. It must be distinctly understood that only the actual photographer or owner of the copyright will be treated with.

*The Editor will not be responsible for the return of artistic or literary contributions which he may not be able to use, and the receipt of a proof must not be taken as evidence that an article is accepted. Publication in **THE GARDEN** will alone be recognised as acceptance.*

Offices : 20, Tavistock Street, Covent Garden W.C.

NOTES OF THE WEEK.

The Indian Bean Tree.—This very ornamental tree, botanically known as *Catalpa bignonioides*, is flowering with remarkable freedom this season. It is a very accommodating tree, flourishing in almost any soil, and even thriving in the smoke-laden atmosphere of large towns. It is, however, seen to the best advantage as an isolated specimen on a lawn. The flowers are followed by long, Bean-like pods, which give this tree the popular name of Indian Bean.

Camellias Fruiting in the Open.—The beautiful grounds of Lady Tress Barry at St. Leonard's Hill, Windsor, have long been noted for their Camellias. Here may be seen hedges and dells of Camellias, and healthy specimens from 15 feet to 20 feet in height. The Camellia is as hardy as the Laurel, and by way of proving its hardiness, many of the trees are now bearing fruits about the size of Walnuts. If the fruits are allowed to remain, the seed will ripen. In fact, self-sown Camellias abound in the gardens at St. Leonard's Hill.

The Cumberland Lodge Vine.—The famous old Vine at Cumberland Lodge, Windsor Park, is again carrying a handsome crop of berries. It is not generally known that this Vine is much larger than the one at Hampton Court. Both are of the same variety, namely, Black Hamburgh, and it is hard to say which is the older of the two. The vinery at Cumberland Lodge is a three-quarter span 138 feet in length. The Vine completely fills this large house, although it is doubtful if it could extend much further, as on hot days the branches furthest from the main stem are inclined to flag. The bunches have been reduced in number, but even now this veteran Vine is carrying 400 bunches of excellent quality.

Treating Hard Seeds with Sulphuric Acid.—In America and other countries where exceptional heat and drought are often experienced just prior to harvesting seeds, it is found that many of the leguminous plants, such as Clover and Melilotus, fail to germinate when sown, presumably on account of the hardness of the outer coating of the seed. The same difficulty has presented itself in this country during recent years among certain varieties of Sweet Peas, especially when the seed has been grown in California. Bulletin No. 312, recently issued from the Cornell University, New York State, is devoted to the results obtained by treating various leguminous seeds, as well as seed of Cotton, with concentrated sulphuric acid or commercial sulphuric acid of about 1.84 specific gravity. The best results were obtained by immersing the seed in the acid for about ten minutes, subsequently washing it with clean water, and either allowing it to dry or sowing it at once. The results obtained in all cases were remarkable, the acid

treated seed giving a much larger percentage of germination than the untreated. We presume that anyone interested in the subject could obtain the Bulletin by applying to the Cornell University.

A Beautiful Annual for Edging.—One of the most beautiful and pleasing of the annual flowers that we have in our garden just now is *Leptosiphon densiflorus hybridus*. A foot-wide edging skirts a pathway for some yards, and whenever the sun is shining the plants are studded with myriads of small, star-like flowers—jewels the ladies call them. These comprise a number of pleasing art shades that are not to be found in any other hardy flower. The plants are about nine inches high. The seeds were sown in the open, where the plants are now growing, early in April. As an annual for edging this little plant is unsurpassed, and it is difficult to understand why it is not more extensively grown.

Vegetables on Waste Land.—One of the most interesting exhibits at the Royal Horticultural Society's meeting on Tuesday of last week was composed of three collections of vegetables that had been grown in the Church Army City Gardens, Stillington Street, Westminster. These gardens three years ago were builders' waste, yet the produce exhibited was, for the greater part, of excellent quality. Indeed, we have never seen better Shorthorn Carrots, red and white Cabbages and garden Kohl Rabi at any local country show. We subsequently had an opportunity of inspecting the plots where the vegetables, as well as flowers, were growing, and were much impressed with the cleanliness and excellence of the whole, as well as the great variety that is being grown. This cultivation of waste spaces is a most praiseworthy movement, and the condition of the plots under notice reflects the greatest credit on the men, also on those who undertake the work of supervision.

Nelumbium Flowers from the East.—When passing through Covent Garden one day last week, we saw, with no little surprise, about a score of the stately blooms of *Nelumbium speciosum*, beautifully arranged in a large decorative basket. The flowers were in the possession of Mr. R. F. Felton, florist, of Hanover Square, who informed us that they had been sent direct from the East over a distance of 2,000 miles, and had taken five days in transit. The flowers are like those of a gorgeous pink Water Lily, borne on long stalks. The largest flower measured 11½ inches across, and the basket of blooms was 5 feet in diameter. The flowers are said to remain fresh for ten days or a fortnight, and for decorative effect and grandeur of individual blooms they are unrivalled. This basket, which is the first of several consignments to be sent, has, we learn, been presented to the Queen. *Nelumbium speciosum* is the Sacred Egyptian Bean, and from the most remote periods has been regarded as the emblem of fertility.

CORRESPONDENCE.

The Editor is not responsible for the opinions expressed by correspondents.

A Good Culinary Pea.—We have this year grown a Pea called Veitch's Prestige, and it has done so excellently that I pen these few words in its favour. The pods are handsome in form, and many carry nine Peas in them. The flavour is superior. Its haulm is very robust, and I should think the striking appearance of the pods would render it suitable for the show table. Its height is given as 3½ feet, but on our strong soil it is rather more.—C. TURNER, *Ken View, Highgate.*

Roses General Macarthur and Richmond.—It was the writer's good fortune recently (July 27) to look round the beautiful grounds of St. Leonard's Hill, Windsor, and while doing so I was shown some remarkable examples of General Macarthur and Richmond Roses. Of these varieties they were the best I had ever seen, particularly of the former. The plants were so unusually healthy and strong and plentifully budded—one growth actually carrying a flower-head of thirty-four buds. Mr. Brown, the head-gardener, said General Macarthur was, with him, by far the better Rose of the two, being equally good for early and late flowering, also most useful for cutting purposes. I suppose this marked difference in its floral behaviour, profuseness in some districts and slackness in others, must be due largely, if not entirely, to a difference in the soils.—C. T.

Exhibiting Carnations.—I have read with much interest, during the last few months, the correspondence *re* the "dressing" of Daffodils at shows, and should now like to ask your readers' opinion as to the showing of Carnations. Last week, for a local show, I set up a nice lot of Douglas' Carnations, all fair blooms and shown as grown, with their own foliage, in vases, as I always show them. The only other exhibit was a collection of somewhat indifferent blooms, "fluffed" out and shown with paper collars on a board. This collection was awarded first prize, and during the afternoon I asked the judge if I had lost first prize owing to my setting up, and he practically acknowledged it and said that mine were the better blooms. Now, surely this is all wrong, and I would appeal to all compilers of schedules to insert below Carnation classes a footnote, such as "To be shown as grown" or "Manipulation of the calyx will disqualify." We have this in our Carnation classes in the Devon Daffodil Society. I am quite sure I shall have Mr. W. A. Watts' sympathy in this matter. What rule has the National Carnation Society on this point?—STRODE. [The National Carnation Society provides classes for flowers shown on boards and others for flowers shown as grown.—ED.]

Crocus cilicicus at Newry.—The first flower of this species opened on the last day of July, thus showing it to be the first Crocus to flower, and also adding one to our list of blue flowers, of which we never have too many.—T. SMITH, *Newry.*

Campanula Zoysii.—Our gardens just now are abloom with Campanulas, but there is none prettier than *C. Zoysii*, one of the dwarfiest and quaintest of the race. It is a dainty little light blue gem with a curiously-constricted neck. Some people find *C. Zoysii* difficult to

next it on my pergola, is cut every year by the cold winds. I have found the Tea Rambler the healthiest of them all, and this year, in spite of a good deal of drought, it has made enormous growths, 12 feet and more long. It is charming in colour and so sweet-scented, and I quite agree with "A." (page 386, August 3) in admiring its handsome foliage.—ESSEX READER.

Hydrangea in a London Garden.—The value of *Hydrangea Hortensia* for gardens in London and other large cities is well demonstrated by the accompanying illustration, which represents a fine specimen growing in Mrs. Batter's garden at Sarsfeld Road, Balham, London, S.W. Mrs. Batter writes: "My *Hydrangea* is 7 feet 4 inches high and has over two hundred flower-heads. Most of them measure 24 inches in circumference. It faces south-west and requires protecting from frost. I find that it likes plenty of water, and I give it weak doses of Clay's Fertilizer twice a week."

Roses Lady Gay and Dorothy Perkins.—One finds quite a conflict of experience regarding these two Roses in different gardens, and a little interchange of this might be useful to those who delight in these rambling Roses. Going through a Scotch garden the other day, where there was a good variety of these Roses, I had my attention drawn to the unsatisfactory appearance of *Lady Gay* as compared with *Dorothy Perkins*. In all cases the former was not looking well, showing a want of vigour in every way and a yellowish colouring of the leaves we do not expect to find in a healthy Rose. This was, it appeared, quite the usual characteristic of *Lady Gay* in this garden, and it is to be discarded, not only because of this, but because the blooms are smaller and not so freely borne as those of *Dorothy Perkins*. The latter is quite a success in the garden referred to, and is grown as handsome pillars and weeping standards. I have observed a somewhat similar thing in several

A WELL-GROWN HYDRANGEA IN A LONDON GARDEN.

other gardens, so that it is not surprising to find some scepticism expressed regarding the alleged superiority of *Lady Gay*. I must say, however, that in my own garden *Lady Gay* is proving all that has been claimed for it, and this induces one to think that the different experiences must be a question of soil or position. In my garden, in practically the same district as the garden mentioned at the beginning of this note, *Lady Gay* is superb, giving just as free growth as *Dorothy Perkins*, and larger flowers more numerous, borne and slightly deeper in colour than *Dorothy Perkins*. Here it is in a sheltered, somewhat cool spot, and the best plants are covering an arch. I surmise that in the gardens where *Lady Gay* does not thrive so well it has a warmer position than is good for it. I do not pretend to assert that this is the cause of the differences which are evident, but others may have something to say on the point which could help to elucidate it.—SUN ROSA.

Rose Conrad F. Meyer.—I was asked to say (page 350, July 13) whether I had given my bushes of *Conrad F. Meyer* any special treatment. They were planted in a new border dug out of old pasture-land, and beyond digging in some manure when the border was made, they have had nothing further done for them. I have done no pruning beyond cutting out a few of the older growths every year, and have let them run up 10 feet to 12 feet high. The border faces east, and they are well protected from the North by higher shrubs.

Rose Tea Rambler.—I have never had this Rose cut by frost, though my garden is very exposed, and the climbing Rose *Réve d'Or*, which grows

Laburnum alpinum.—It is extraordinary, to my mind, how comparatively little *Laburnum alpinum* is grown, as it is far in advance of the common *Laburnum*. This probably happens because it is little known. I find it grows taller and flowers more abundantly than the ordinary form, while its long, pendent racemes of flowers are very graceful, reminding one of *Wistaria multijuga* in shape and length of raceme. The true Scotch form should be obtained from a reliable firm of nurserymen.—B., *Weybridge*.

The Indian Horse Chestnut.—In reference to the interesting note on *Æsculus indica* published in the issue of July 27, page 376, I look upon this tree as one of the most ornamental Chestnuts in cultivation. I am sending a photograph, showing a raceme of daintily-coloured flowers above the shining green foliage, which was taken from a tree in a Surrey garden in June of the present year. It is a great pity that it is a little less hardy than the majority of the Chestnut family, but in the Southern Counties, at all events, it appears to grow well, as is evidenced by the trees at Barton in Suffolk, which are between sixty feet and seventy feet in height. It is a native of the Western Himalaya, where travellers say it is found growing at an elevation of 8,000 feet to 10,000 feet.—SPARTAN.

A Useful Cool-House Orchid.—The genus *Oncidium* contains many fine species, but *O. macranthum* is undoubtedly among the best, and a strong point in its favour for an amateur is that it will thrive in the cool-house among the *Odontoglossums*. The leaves are from 15 inches to 20 inches long, and the scapes sometimes reach a great length, while these are occasionally branched. Some growers train them along the roof, but the usual plan is to place three or four stakes in the pot and carefully tie the spike round. A charming effect is thus produced. Each flower is large, chiefly yellow, shading to olive brown, with a tinge of violet purple on the lip. The cultural details are simple. Always keep the compost in a sweet condition, and when it is deemed necessary to repot a specimen, the spike should be pinched out to give the plant a chance to recuperate. Otherwise it needs the same treatment as *Odontoglossum crispum*.—S.

FORTHCOMING EVENTS.

August 12.—United Horticultural Benefit and Provident Society's Committee Meeting.

August 13.—Royal Horticultural Society's Meeting and Exhibition of Gladioli. Lecture at 3 p.m. by Mr. Pulham on "The Construction of the Wisley Rock Garden." Clay Cross Flower Show.

August 14.—East Anglian Horticultural Club Meeting. Exmouth Show (two days).

August 15.—Malton Flower Show. Blairgowrie Flower Show. Wylam Flower Show. Capel Flower Show. Merthyr Tydvil Show.

August 17.—Urmston Horticultural and Poultry Show. Burnley Flower Show. Seascale and Lake District Flower Show.

August 21.—Shrewsbury Flower Show (two days).

TREES AND SHRUBS.

THE PROPAGATION OF SHRUBS FROM CUTTINGS.

ALTHOUGH the propagation of some kinds of shrubs from cuttings offers no difficulties to those who have an insight into the elementary details of propagation, there are others which require a more intimate knowledge of their peculiarities before they may be increased with any degree of success; therefore in the ensuing notes attention is directed to a few points worthy of consideration by the beginner. As a rule, July, August and early September are the best months in which to take

THE INDIAN HORSE CHESTNUT (*ÆSCULUS INDICA*).

cuttings, although even May and June are not too early for some kinds.

Generally speaking, two kinds of soil are sufficient for most shrubs—that in which peat predominates for one kind, and that where loam forms the principal part for the other kind. In each instance a fair amount of sand is necessary, and the two composts may be formed as follows: Take two parts of good peat and mix with it one part of silver sand. Leave some of the compost in a roughly-broken condition and pass the other through a half-inch meshed

sieve. For the other mixture three parts of fibrous loam, one part of leaf-mould and one part of silver sand are necessary. As in the other case, some must be left rough and the remainder be passed through a sieve.

Clean pots are in either case a necessity, and ample drainage is required. As a rule, the latter may be obtained by filling the pots one-third with clean crocks. Over these place some rough material, then the coarser soil, and fill up to within a third of an inch of the top with fine soil. Over the whole a layer of silver sand may be placed. In each case the compost must be made firm in the pots, but in the instance of the peaty soil it must be specially firm. Pots from 3 inches to 6 inches in diameter are, as a rule, more satisfactory than either larger or smaller ones.

The convenience at the disposal of the propagator must decide where the cutting-pots are to be placed. In any case a close atmosphere is necessary, but whether this is provided by a cold or a warm frame is immaterial in some cases, for the cuttings may be expected to root as well in one as in the other, with, of course, a difference in time. There are instances, however, of cuttings which will not root in violent heat, others which object to artificial heat of any kind, and others, again, which root better if given a fair amount of artificial heat.

The Right Kind of Cutting to Select.—

It is only by actual experience that one is able to decide when the cuttings are in the best condition for rooting quickly. As a rule, young shoots are in the best stage for rooting when they are becoming a little firm, especially when a fair amount of heat can be given. For those that require cold-frame treatment entirely, the cuttings are usually more satisfactory if allowed to become somewhat more firm. As early as the third week in May short shoots of *Diervillas*, *Forsythias* and *Philadelphuses* may be taken. At that time they may be placed in a warm propagating-case or in a hot-bed, and will root within a fortnight. If, however, cuttings of the same shrubs are left until the end of July, they take a long time to root, and do not start away so vigorously as those taken at an earlier date. June and July, however, may be accepted as suitable months for *Spiræas*, *Prunus triloba*, *P. japonica* fl.-pl., *Escalonia*s, *Kerria japonica*, species of *Rose*, *Laurels*, *Aucubas*, *Tree Ivies*, *Olearias*, *Cornus Spaëthii*, *Viburnums*, *Honeysuckles*, &c. July and August are the best months for *Heaths*, *Rhododendrons* and kindred shrubs. As a rule, cuttings 4 inches to 5 inches long are more satisfactory than longer ones; but in the case of members of the *Erica* family they must be shorter, and in

the case of the various *Heaths* they are made, as a rule, from 1 inch to 1½ inches long. With such delicate cuttings as *Heaths* great care must be taken in trimming the leaves away from the lower parts, for if the bark is injured in any way, the chances of rooting are diminished. Although it is not possible to give any hard-and-fast rule for the depth to which the cuttings must be inserted in the soil, a good average may be suggested as one-third the depth of the cutting. It is very important, however, that the bases of

the cuttings should fit firmly on the soil and that they should not be left in a condition which is popularly known as being "hung," that is, secured near the surface of the soil and left loose below. Full use must be made of the outer margin of the pots when inserting cuttings, for those in that position root more quickly than others nearer the centres of the pots. As soon as inserted a thorough watering must be given, and the pots must be placed in the positions where they are to remain until the cuttings are rooted. A warm propagating-case or hot-bed of manure will suffice for warmth-loving subjects. Plunge the pots in Cocoanut fibre, for that helps to keep the soil moist without over-watering. Cases and frames must be kept close, and in the case of Heath cuttings a bell-glass placed over each pot will do good.

Cuttings to be placed in cold frames are best dibbled into the soil of the frame. Two subjects which root well in cold frames, but are a failure in heat, are *Berberis stenophylla* and the double-flowered Gorse. Other things which may be placed in the same frame are Brooms, conifers such as variegated Yews, varieties of *Cupressus lawsoniana*, *pisifera* and *obtusa*, varieties of *Thuja*, &c. Hollies may also be rooted in such a frame. Give a good watering when the cuttings are inserted, and keep the frame close and shaded from bright sun. Very little subsequent watering will be necessary, but the cuttings must not be disturbed until the following April. As the cuttings begin to form roots, the cases or frames may be gradually ventilated until the young plants are hard enough to remove, when they may be placed in a cold frame for the winter.

CEANOTHUS AZUREUS GLOIRE DE VERSAILLES.

ANY reader requiring to cover a south wall should try *Ceanothus azureus* Gloire de Versailles. *Ceanothuses* have been flowering profusely this summer, possibly from the ripening they received last year. None has been more beautiful than *C. azureus* Gloire de Versailles, which has been, with me, a sheet of bloom for weeks past. As the plant shown in the illustration had encroached over the bed in which it is growing, I cut it back in March last, with fear and trembling that doing so might injure the flowering this season; but to my joy I found my fears were not justified. I do not protect this plant or the one on a north-west wall, but I find that the one with a south aspect always produces much more flower than the other. It does not appear to be fastidious as to soil, although I presume it would not thrive in heavy clay, unless coarse sand and thorough drainage were provided. As will be seen in the illustration, it flowers very freely indeed, and is certainly one of the best of our hardy shrubs that bloom during the summer, when blue flowers of any kind are none too plentiful.

Weybridge

B.

THE ROSE GARDEN.

ROSES WITH BAD HABITS.

(Continued from page 379.)

Mrs. R. G. Sharman Crawford, exquisitely beautiful in colour, is terribly addicted to mildew, and unless checked will soon taint all the Roses in its neighbourhood. Now that we have a plethora of pink Roses, I know of many growers who are discarding the old favourite.

General Macarthur should not receive a bad word perhaps from the writer, who has on so many occasions recommended its culture, but one cannot be blind to the fact that the full blooms are very

enough to find it a success. If any reader has succeeded in maintaining this Rose in a vigorous state for some years, I should be pleased to hear of his method; but with me it seems to dwindle away with a sort of sleeping sickness. It seems a very unfortunate fact that both with Mrs. Edward Mawley and the more recent

Edward Mawley there should be bad points to chronicle, and I very reluctantly do so, knowing that these two ardent rosarians are held in such high esteem by the whole Rose-loving public. But, of course, they are not responsible for the bad habits of their namesakes. Incidentally, I may mention that a reporter of one of the Belfast papers, in reporting the recent National Rose Society's Show, was perhaps slightly anticipating events when he alluded to our friend as "Sir Edward Morley," for who can say but that this honour has been richly earned, whether it is ever bestowed or not! Now as regards the Rose, it has been very disappointing to most of us. It "blues" terribly, and if there is one good scarlet-crimson bloom out on a dozen plants, the others are all of a violet blue shade, and exceedingly thin also. Possibly in autumn it may be grand, for I cut a fine bloom yesterday.

Horace Vernet has been seen very fine this year, but amateurs who are not "in the know" should be careful how they order this Rose, for it will almost certainly disappoint them as a "cut-back" flower, and unless one is prepared to bud some stocks each year, my advice would be to leave the Rose alone.

Medea is a Rose we may sometimes see looking splendid in a box of Teas, but has anyone found it to be a good Rose in the garden? Most of its flowers fail to open well, although now and then a superb bloom may be cut.

Alice Lindsell is a very uninteresting Rose on the plant. There is far too much "stuff" in it to open freely, and unless shaded the blooms "ball" badly, and if a little wet will rot rather than expand.

Florence Pemberton is another splendid Rose when shaded, but whose blooms come very "soiled" when left to their own devices, the petals being far too thin and papery.

Nita Weldon is a very lovely Rose in the show-box, but it hangs its head in such a dejected fashion on the plant as to be useless in the garden. (To be continued.)

ROSE MRS. DAVID JARDINE.

WHEN Messrs. A. Dickson and Sons sent out this lovely variety four years ago, I predicted that it would have a large demand as a forcing Rose, and my prediction has been fulfilled. Apart from its glorious even colour of bright rosy pink, it possesses such beauty of form and the stems as to render it one of the handsomest of the Hybrid Teas, and its strong fragrance will commend it to all who can fully appreciate this delightful attribute. P.

CEANOTHUS AZUREUS GLOIRE DE VERSAILLES IN A WEYBRIDGE GARDEN.

flat and the colour inclined to a magenta shade, which often will mar the colour effect when the Rose is massed in a bed. I am quite ready to admit that its good points outnumber its bad, but the fact remains as stated, and I am hoping the General will soon be improved upon.

Charles J. Grahame should not have been placed among the Hybrid Teas. It is grand in colour at times, but generally woefully disappointing, the older flowers changing to a dull shade, and all are very thin.

Mrs. Edward Mawley, superb as a one year old plant from half-standards, is of little value as a cut-back; at least, I have not been fortunate

THE ROCK AND WATER GARDEN.

HARDY FERNS IN THE ROCK GARDEN.

In gardens where a cool corner can be given up to hardy Ferns, a charming feature can be introduced at a trifling expense which will remain full of interest and beauty for the greater part of the year, and during the hot days of summer will be one of the most popular resorts in the garden. Ideal natural positions for hardy Ferns occur on many estates, but the West and South-West Counties and many parts of Northern England and Scotland are peculiarly adapted for the purpose, as thereabouts the atmosphere is moist, and numerous shady, rocky glens or valleys are to be found in which waterfalls sometimes occur and rock-strewn streams wend their way, causing the surrounding ground and atmosphere to be constantly moist and cool. Where these favourable conditions do not exist, however, it is often possible to introduce them without any serious trouble, and when a rock garden is being made a portion can easily be so arranged that it will form an ideal home for Ferns.

In Conjunction with the Rock Garden.—Shady places sometimes occur in a scheme of rock gardening, and such places are not fit for sun-loving alpine plants, yet they form good positions for Ferns, especially if water can be introduced in such a manner that it trickles over and between rocks, forming here and there miniature waterfalls, beside which are cool recesses or caves for the accommodation of such a moisture-loving subject as the Killarney Fern, which likes to have its leaves in a constantly moisture-laden condition. In fact, there are very few districts where a collection of hardy Ferns may not be grown, although the number of kinds which should be planted depends entirely on the locality. In Cornwall, for instance, the owner of a garden can select from a much wider field than he whose garden is situated in a less favourable climate.

Kinds to Grow.—The Australian Tree Fern (*Dicksonia antarctica*) is considered a hardy plant in Cornwall, and even in some gardens on the West Coast of Scotland it stands uninjured; but in most parts of the country it would be a distinct failure planted anywhere but under glass. Where it is grown, however, it adds an air of distinction to the garden, for its brown stems standing high above low-growing kinds are distinctly pleasing, while the heads of large fronds allow sufficient light to filter through to supply the requirements of any undergrowth. Other exotic Ferns may be grown with this Tree Fern, one notable kind being *Lomaria procer*, whose dark green vigorous fronds are always pleasing. Without these semi-tender kinds there are many British species and several exotics, all of which are quite hardy and amenable to cultivation, they may be grown in almost any place where the soil is suitable and moist conditions prevail.

The Royal Fern (*Osmunda regalis*) always finds admirers, for its large and stately fronds, which may be from 4 feet to 6 feet in height, are certainly the most conspicuous among British species. It appears to rejoice in light ground, standing just clear of a stream, where the roots can enter the water. *Scolopendrium vulgare* (the Hart's-tongue Fern) is another popular kind which should be well represented in the hardy fernery. It has hosts of varieties, many of which are very prettily crested. There is no need, however, to obtain a collection of the fancy named sorts, for the type is quite as useful for ordinary purposes, and nothing more effective can be desired than the manner in which this plant furnishes roadsides, banks of streams and walls in Devonshire and Cornwall. The Hard Fern (*Lomaria spicata*) is another charming species which is found in moist woods, walls and heathland all over the country, even at a considerable elevation. Vigorous

divided into linear segments, are found clothing many an old wall, bank or tree branch. For crevices between rocks it is well adapted, for it thrives where soil is scarce, providing moisture is plentiful. One of the finest effects made by this Fern which has come under the writer's notice is in the gardens at Mount Edgcombe, for there the branches of a number of trees are literally covered with the species.

The Hardy British Maidenhair (*Adiantum Capillus-Veneris*) may be planted in chinks between rocks where it can obtain plenty of moisture, its popularity and beauty entitling it to a trial wherever a hardy fernery is formed. *Adiantum pedatum*, a native of North America, is another Maidenhair which may be cultivated out of doors. As it grows from 9 inches to 15 inches high, a well-grown plant is a conspicuous object. The Irish form of *Trichomanes radicans* may be

HART'S-TONGUE AND OTHER FERNS IN THE ROCK GARDEN.

examples have their narrow fronds upwards of a foot in length, but in other places they scarcely attain a length of 6 inches. It is excellent for planting about the banks of a stream, among rocks or in other places, and looks well either in small or large patches. *L. alpina* is a good companion plant.

In mountainous districts in Scotland, Wales and various parts of England the pretty little Parsley Fern (*Cryptogramme crispa*) is to be found, and patches of this ought certainly to be planted in the hardy fernery. The short fronds are made up of small delicate segments, and are very attractive. A moist position among broken rock suits it. The Oak Fern (*Polypodium Dryopteris*) is another charming little Fern which is found wild in many parts of the country. It thrives admirably in light, moist ground, and is a general favourite. *Polypodium vulgare* is well known in some parts of the country, for its narrow leaves,

grown in a shaded place where it will be constantly covered with moisture, but it must on no account be exposed to sun or drying winds. Then there are *Aspidium aculeatum*, *A. angulare*, *Asplenium Filix-fœmina* and *Nephrodium Mas*, all with hosts of varieties, which alone would furnish a large fernery, which can be utilised, in addition to such species as *Asplenium Ceterach*, *A. Adiantum-nigrum*, *A. Trichomanes*, *Nephrodium spinulosum* and others. Such allies as *Lycopodium clavatum*, *L. annotinum*, *L. complanatum* and *L. Selago* might well be introduced in the cooler parts of the country, while *Selaginella selaginoides* may be grown in many places and *S. kraussiana* in the warmer parts of the country.

In most cases it would be a mistake to include the Bracken, for it is a most difficult plant to keep within bounds, and there would be a danger of its crowding out choicer subjects. People who have the convenience and do not already possess

a fernery of hardy Ferns would do well to commence the culture of these pretty plants, for they are always a source of pleasure. L. W. P.

A YUCCA FOR THE ROCK GARDEN.

(*Y. ANGUSTIFOLIA.*)

THE long spell of dry, sunny weather during the summer and autumn of 1911 is probably responsible for the freedom with which Yuccas are flowering this summer. One of the rarest and most distinct of the Adam's Needles or Yuccas is *Y. angustifolia*. It is a native of Missouri, Colorado and New Mexico, and is figured in the *Botanical Magazine*, t. 2236. The Narrow-leaved Adam's Needle, as it has been appropriately named, is quite a modest plant in growth, with long, narrow leaves averaging about two feet long and three-eighths of an inch wide. The inflorescence is simple, about three feet high, the individual flowers 3 inches to 4 inches across, cream-coloured, opening in the end of June and early July. This charming Yucca is seen to the best advantage when planted in the rock garden in light, sandy loam.

FLOWER GARDEN.

SEASONABLE NOTES ON CARNATIONS.

The Flowering Season.—I hope that my experience has been similar to that of all readers of THE GARDEN this season, because, if so, they have had a most delightful time. My plants have flowered splendidly, as well in regard to profusion as to quality of size, shape and colour in individual blooms. It is not the rule in my garden to carry disbudding to the last degree, but there have been wonderfully fine flowers in threes attractively arranged on a stem. The plants have not suffered from any cause, though at one time they suddenly became the prey of myriads of green fly, of which an end was promptly made, or the cherished plants would quickly have been ruined. The "grass" was exceptionally good, and there were plenty of excellent layers.

Rooting Layers.—Growths which were cut in the orthodox manner about the middle of July are looking satisfactory from every point of view, and if the present promise is maintained, there will not be more than one or two per cent. of failures. It is necessary to keep the mound of soil pleasantly moist to encourage rooting, but care must be exercised not to make it sodden, or more harm than good is bound to follow. Leaves that commence to turn yellow may be reduced in length to remove the unsightly portion, while those that die ought to be immediately removed and burned. Loosening of the surface of the mound is desirable, but it will have to be done with the greatest care, or the layers will be disturbed and the prospects of success seriously

prejudiced. Use a small fork merely to prick into the top half-inch, or a bluntly-pointed stick to scratch it over.

Layering.—If the process of layering is not yet completed, it is necessary that it shall be finished at once, because unless the young plants are well rooted before activity ceases for the year, it is most probable that the losses during the winter months, irrespective of whether the plants are to be in the open ground or in small pots in frames, will be numerous. The later the work is done, the more care is demanded, not only in selecting

against the system is that the Carnation is a perfectly hardy plant, and that it is, consequently, wholly unnecessary to go to the trouble entailed by wintering under cover. This is all very well as far as it goes, but, unfortunately, the majority of us find that we lose some plants in the winter when they are out of doors, and it is invariably those which we were most desirous of saving; hence the advice to keep on the safe side even at the expense of a little more labour. It is well, too, to prepare the soil that is to be used for potting in advance of the actual time of use, because nothing will then have to be done except the potting. The popular mixture of soil upon which amateurs rely for so many plants answers admirably. It consists of three parts of sound, fibrous loam and one part of leaf-mould or flaky refuse manure, according to convenience, with enough sharp sand to keep it quite sweet and open. Mix the ingredients perfectly three weeks or so before the soil will be wanted, and let it lie in a heap meantime. It is wise, also, to prepare the pots and crocks, both of which ought to be scrupulously clean at the moment of use.

Plants after Flowering.

—Many cultivators throw away their plants when they have flowered once, but it is not necessary that this should be done, as they will bloom splendidly the following year. It may be necessary to thin out the growths beyond that which has been done in layering, and a top-dressing of excellent soil, such as a mixture of loam and manure, ought always to be put on them. F. R.

THE CAUCASIAN SCABIOUS.

ONE of the most ornamental and most appreciated of our hardy border flowers is the Caucasian Scabious (*Scabiosa caucasica*), which is also highly prized as a cut flower for exhibition or for the decoration of the dwelling. It is of good growth, while the long stems on which the flowers are borne increase its value for cutting. The Caucasian Scabious grows from one and a-half feet to about three feet high, according to the nature of the soil, and it usually bears a considerable number of large flowers of a pretty

lilac; the form is also highly pleasing, the broad-rayed petals going well with the forets of the disc.

The plant is rather variable in the size of bloom and in the shade of colouring, and some of the select forms are worthy of being chosen when purchasing plants. The white one, *alba*, is appreciated by many, although the colour is more creamy than pure white even when the blooms expand. They afterwards pass off to a good ivory white. The lilac and blue varieties are generally excellent, and one of the finest of these is that called *amena*, which has soft-coloured, large flowers of much substance. Another, named

A RARE YUCCA, *Y. ANGUSTIFOLIA*, FLOWERING AT KEW.

the most suitable shoots, but also in making the cut in the correct place, since woodiness increases with the age of the growths. It will, therefore, in all probability be wise to strip off more leaves than in July, and to make the incision a little higher up the shoot.

Soil for Potting.—In gardens where the soil is extremely close and heavy, and particularly so when the situation of the place is low, it is excellent practice to winter the young plants in small pots in cold frames; and the same may be said of at least a portion of the stock in all places where the choicest varieties are grown. The argument

magnifica, is of even superior excellence, with truly fine flowers of the best form and of pleasing colour. In one called perfecta we have a good variety with flowers of a darker shade than those given by the majority of the plants of *S. caucasica*.

The named varieties are propagated by division, preferably in spring or when the plants have finished flowering; but as they bloom comparatively late—from August until October—spring division is the more suitable. A good stock of plants may be procured from seeds, these being sown in pots or boxes under glass in early spring and treated in the same way as other perennials. Occasionally seeds of the white variety may be obtained, and a large proportion of these will come true.

The Caucasian Scabious is hardy, and its only fault is that in some poor soils the flowers may not come perfect through the absence of one or more of the ray petals. This is a great deformity, and when such occurs the soil should be well enriched with good manure. As a border flower this plant is highly attractive when properly grown.

Dumfries.

S. ARNOTT.

ORIGIN OF SHIRLEY POPPIES AND OTHER FLOWERS.

[In Answer to a Correspondent.]

To answer all your questions fully would require a whole number of our journal. The raiser of the beautiful Shirley Poppies was the Rev. W. Wilks, the secretary of the Royal Horticultural Society. We cannot do better than give their story in his own words: "They originated in this way. In 1880 I noticed in a waste corner of my garden, abutting on the fields, a patch of the common wild Poppy of the cornfields—*Papaver Rhæas*—one solitary flower of which had a very narrow white edging to the four petals. This one flower I marked and saved the seed of it alone. Next year, out of perhaps 200 plants, I had four or five of which all the flowers were white edged. The best of these were marked and the seed saved, and so on for several years, the flowers all the while getting a larger infusion of white to tone down the red, until they arrived at quite a pale pink, and one plant absolutely pure white in the petals. I then set myself to change the black central portions of the flowers, the anthers, stigmatic surface and pollen, from black to yellow or white, and succeeded at last in obtaining a strain with petals varying from the brightest scarlet to pure white, with all shades of pink in between, and with all possible varieties of flakes and edged flowers, and having golden or white stamens, anthers, stigmatic surface and pollen, and a white base to each petal. The Shirley Poppies have thus been obtained simply by selection and elimination."

The Sweet Pea was introduced from Sicily in 1700, but its native country is not quite certain. Its numerous varieties have been obtained partly by spontaneous variation, partly by cross-breeding. The garden Pentstemons are largely derived from hybrids between *P. Cobæa* and *P. Hartwegii*, but perhaps other species have been used. They occur wild in Western North America for the most part. Petunias as we know them are the result of crossing *Petunia nyctaginiflora* and *P. violacea*, both of which occur wild in South America. So with all the other plants you mention. The wild progenitors are frequently very different from, and far less showy than, the plants as we know them in gardens, but their wild forms do occur somewhere, though it may be far distant. The history of many of our garden flowers is scattered through old florists' books and periodicals.

THE KITCHEN GARDEN.

ARTIFICIAL MANURES FOR VEGETABLES.

THESE is now no doubt that artificial manures may be economically used in market gardening, though experiment shows the advisability of not relying exclusively upon them. A dry season may upset calculations, and a full manuring with manure, costly as it is compared to the other fertilisers, is likely then to pay far better. A judicious combination seems to give the best results, but more experiment is wanted. The land at Hadlow (from which most of my knowledge is based) is on clay. However, nearly twenty years' experience at this station has clearly shown the value of the usual mineral dressings to which farmers are accustomed.

Another point gained, in some cases at any rate, is that of quality, though fast-grown green vegetables may in some cases perhaps lose in flavour. At any rate, I have noticed this when growing

THE LATEST PEAS.

THOSE who have a good alluvial soil and like dishes of Peas as late as possible will find that certain varieties are much better than others. A light, shallow soil will grow excellent early Peas if it is well enriched with manure, but for late crops it is necessary to give a deeper rooting medium and, if possible, land of a more retentive nature. Of course, late in the season it is necessary to sow a dwarf or medium grower, and there are some excellent varieties, such as Sutton's Selected Gladstone, 3 feet to 4 feet high, with remarkable vigour and one which is a splendid drought-resister. The older Gladstone Pea was, and is now, much grown for its lateness, but the Selected is superior, and there is no difficulty in having this variety well into November. When the Gladstone type of Pea has been exhibited at the late autumn shows, I have invariably noticed that the exhibitors have been successful, as the pods, though a trifle smaller than some, are so tightly packed.

The older Veitch's Autocrat, which received a first-class certificate from the Royal Horticultural

SHIRLEY POPPIES GROWING NATURALLY IN AN OPEN WOODLAND SPACE.

Spinach on a small scale with nitrate and sulphate of ammonia combined with manure. The plants were decidedly insipid, more so than adjoining material in un-manured ground.

Phosphates in the form of basic slag or superphosphate may be safely used for root crops, Cabbage of all kinds, including Cauliflower and Broccoli, and, in fact, generally, as it is the next important constituent of manure to nitrogen. For second crops, such as spring Cabbage, for example, a few hundredweights of superphosphate on land previously manured for the first crop prove expeditious and economical, though probably without nitrate of soda in the spring a poor crop would result. Spring-planted crops are rather more exacting, as they suffer more from drought, and it would seem inadvisable not to include some manure, except, of course, for Carrots and Parsnips, which, with winter Lettuce and winter Spinach, are crops that can grow in a fertile soil without an immediate application of manure of any kind. Speaking generally, it is the judicious use of artificials in conjunction with farm-yard manure that gives the best results.

G. T.

Society many years ago, still maintains its excellence as one of the best late Peas we have. It has by no means a huge pod, but is of very fine quality and there is no waste, as the pods are quite full. It is a heavy and continuous cropper, with the Ne Plus Ultra quality, grows 4 feet high, and is so well known that I need not describe it. I would ask those who like late Peas in October and November to give Autocrat a trial, as its freedom from mildew and capability to thrive in a dry season place it in the front rank of good late varieties.

Another very fine late Marrowfat Pea is Carter's Michaelmas. This is dwarfer than those named above, and in my experience is the latest variety to set its blossom freely. It is of dwarf, bushy habit and quite free from mildew. The pods are produced in pairs, are large and of a very dark green, and the Peas much wrinkled. It is a remarkably heavy cropper, and though termed the Michaelmas, it may be had in excellent condition well into November. Owing to its dwarfness it is admirably adapted for gardens limited in size. This variety has for some years been grown extensively for August and September cropping, but

I would recommend it for later supplies, sowing specially for that purpose.

Latest of All is a variety less known than those already noted, and, as its name implies, is one of the latest Peas grown. It is a Pea with remarkably rich flavour considering it is produced so late in the season. The pods are not quite so large as those of Late Queen, but the produce is so good that it is one of the most profitable for November gathering. The pods are produced in pairs, and they are borne in great profusion on a dwarf bushy haulm of strong constitution, thus making it most valuable for a shallow soil if given ample manure and grown in trenches with plenty of moisture.

Late Queen is probably better known than most of the foregoing, and, though by no means new, is still one of the most reliable late varieties grown. It is only 3 feet to 4 feet high, of robust constitution, a good one to resist mildew and of splendid quality. There are others, but those named will

Although it seems hardly probable that the Apple mildew will create such havoc as the American Gooseberry mildew, it behoves fruit-growers to adopt more energetic measures to combat its further increase. For two years in succession I have found the fruits of Lane's Prince Albert badly affected with this mildew, the consequences of which have been that the fruits have remained exceptionally small and have been of little marketable value.

According to the Apple Tree Mildew Leaflet, No. 204, issued by the Board of Agriculture and Fisheries, the winter or assigerous form of fruit of this fungus is very rare. I have good reason for thinking, however, that such is not the case, as on several occasions I have found the assigerous stage of this fungus on the fruits of the Apple. Certain varieties of Apples are undoubtedly more susceptible to this disease than others. I have found that Lane's Prince Albert, Bismarck,

I have no doubt whatever that nurserymen are the universal distributors of this disease, as I have frequently seen thousands of Crab and Paradise Apple stocks smothered with this mildew in several large nurseries. These infected stocks are ultimately budded or grafted with the choicer varieties of Apples, the consequences of which are disastrous to the future healthy development of the trees. F. E. T.

PEACHES.

TREES that are bearing heavy crops should have bountiful supplies of water, both clear and as liquid manure, to assist the fruits to swell to a good size. The foliage, too, must be kept free from insect pests by the frequent use of the syringe on bright afternoons till once the fruits show signs of ripening, when syringing should cease. If not already done, finally thin the crops of late kinds, leaving only just the number of fruits required to mature. I am greatly in favour of thinning both Peaches and Nectarines before the stoning process, so as not to overtax the trees at that critical period. The number of fruits left to ripen should be regulated according to the size of the variety and the strength and growth of the trees. Attend carefully to all fresh growths, keeping them neatly secured to the walls or trellises, and if more shoots have been left than will be wanted for next year's crop, thin them out so that the remaining ones may have all the chance possible to grow into sturdy, fruitful wood. Although a goodly number of young shoots may have been removed at the time of disbudding, there are generally others that can be spared as the growths extend, and which, if left, will have to be pruned away in winter. Overcrowding of young wood is most detrimental, and should never be allowed by those who have the trees under their care. The early American varieties are among the first to ripen outside, but if left on the trees too long the flesh becomes woolly and tasteless. They should be gathered with great care a few days before they are ripe, and be taken to the fruit-room or some other dry, airy place to finish, the fruits then being very passable. The midseason kinds—Royal George, Dymond, Stirling Castle, Bellegarde, Noblesse and others—are always excellent, but very late kinds require a good position to bring the fruits to perfection, and in the colder parts they probably would fail to ripen. With us Sea Eagle succeeds well, also the Nectarine Peach and Princess of Wales when the autumn is dry and warm. If carefully looked after, Peaches may be grown outside with every success, and I think they are fully as profitable as any other fruit. All fruits to be sent a long distance must be gathered when perfectly dry and under-ripe, and should be packed carefully in some soft material. I use wood-wool, and am well satisfied with the way they travel and arrive at their destination. The fruits are first placed in soft tissue paper, and then embedded in the material mentioned tight enough to keep them from shaking in the boxes. The boxes are then tied with string and labelled in red ink "Fruit.—With care."

Wrotham Park, Barnet.

be ample to select from where late Peas of the best possible quality are required. G. WYTHES.

THE FRUIT GARDEN.

APPLE MILDEW AND ITS TREATMENT.

AMONG the many fungoid diseases which fruit-growers have to contend with, that of the Apple mildew (*Podosphaera leucotricha*) is of increasing importance. During the past few years it has assumed an almost epidemic form in many fruit-growing districts of this country. Where trees are persistently attacked by this mildew, the growth of the young shoots becomes stunted, and in some cases they are completely killed. The blossoms are also liable to infection, and when this happens there is little prospect of the ultimate production of fruit.

Allington Pippin and Cox's Orange Pippin are most liable to become badly affected throughout the fruit-growing districts of Cambridgeshire.

The dissemination of the disease is no doubt due to the profusion of conidial spores which are produced on the young shoots. These summer spores are readily dispersed by the wind and other agencies on to neighbouring trees; consequently there is ever an increasing area of infection unless preventive measures are adopted. Occasionally spraying the trees while the disease is active with a solution of sulphide of potassium will be found most effective in checking its rapid increase.

As the mycelium of this fungus is also believed to be present in the bark of the affected shoots, fruit-growers should adopt the additional precaution of cutting back during the winter all young shoots which have been known to be affected. All such prunings should be burnt and not allowed to lie about on the land.

GARDENING FOR BEGINNERS.

TREATMENT OF RAMBLER ROSES AFTER FLOWERING.

AT this season, when most of the Rambler Roses have finished flowering, there is some important work that requires attention if we are to get the best from our plants next year. Slowly but surely the novice in gardening is taking up the cultivation of the many beautiful hybrids of the Japanese Rosa wichuraiana, and there are not many gardens in the country where such varieties as Dorothy Perkins and Hiawatha do not find a home. Their rapid growth and free-flowering characters render them particularly suitable for growing over arches, pergolas, or on rustic trellis fencing, and gardens of the present day owe not a little of their beauty to the judicious use of Rambler Roses.

If we examine our plants now, we shall, or we ought to, find a number of strong, wand-like shoots that have been formed during the present summer. These, in many instances, notably Crimson Rambler, emanate from the base; but in some cases, and particularly in Dorothy Perkins, they may be found coming from the older wood some distance from the ground. But no matter whence they spring, these are the growths that we want to look after, as it is upon these that we shall secure our best flowers next year. What we want to do now is to give these young growths every opportunity to become well ripened before the winter, and with this end in view any old, useless wood that may be present should be removed at once. It is difficult to describe the character of this old wood, but an inspection of a Rambler Rose, even by the merest novice, will reveal branches that it is evident have done their best, and which may well be superseded by the younger ones. After cutting these out, the young shoots that we wish to retain should be tied up loosely, just so as to prevent them getting damaged.

If tied in closely to the supports, sun and air do not reach them so freely. Green fly is often present in the tips of the young shoots, and where this is so it must be removed by spraying, or, better still, dipping them in some good insecticide.

With large-flowered Rambler Roses such drastic pruning cannot now be adopted, but even in these varieties no harm, but rather a great deal of good, will be done by cutting out old wood that is obviously past its best. The use of these larger-flowered, semi-climbing Roses for pillars and arches is now largely adopted by those who like them for cutting, and the accompanying illustration of the old variety Homère shows that they are capable of producing very pretty effects in the garden. This arch is in the Vicarage garden at Shalford, a little village about five miles from Braintree in Essex. Here the Rev. A. Law grows Roses and Sweet

Peas in profusion, and when we had the pleasure of seeing his garden one day in June it was filled with the delightful fragrance of these two flowers.

MIGNONETTE FOR THE WINTER.

This deliciously fragrant flower is admired by everyone, whether it be in the open ground or in the greenhouse. When the autumn frosts have cut off our supply out of doors, a few pots under

sturdy growth must be encouraged. In autumn, before the nights get too cold or the rainfall too heavy, the pots must be taken into the greenhouse and given a good light position therein. In this way the plants will flower when the fragrant blossoms are most appreciated. H. P.

SUCKERS ON FRUIT TREES.

If a comparatively young fruit tree throws up a single sucker from its roots and the cultivator is content to simply pull off that sucker, more will soon grow. I have seen many scores of trees treated in this way, and in a few years' time the ground under them was fairly well covered with young sucker shoots. It is a very difficult matter to clear the main roots of these growths when the latter have been left for so long a time undisturbed except the annual removal of their tops. I strongly advise inexperienced cultivators to forthwith remove all suckers as soon as they are seen. Merely breaking them away at the soil-level will not do; the soil must be carefully removed right down to the main root of the tree from which the sucker grows, and then the latter must be cleanly cut away with a small portion of the root attached to it. There is not much labour entailed in the removal of one or two suckers from each tree, but a great deal if neglected for several years. The cut part of the root from which the sucker is taken may be notched with a sharp knife; then many fibrous roots will grow from it. Avon.

A BEAUTIFUL ROSE ARCH IN A VICARAGE GARDEN IN ESSEX.

glass are doubly welcome, and in order to obtain these, seeds should be sown now. Pots 5 inches in diameter are very suitable for the purpose. They should be quite clean and effectually drained. A suitable compost for Mignonette should consist mainly of good loam of a fairly holding nature, lightened by a little old broken mortar rubble and silver sand. It is necessary that the soil be pressed down very firmly, as this ensures good stocky growth. The seeds must be sown thinly, and when sufficiently advanced, so that the best can be selected, the seedlings must be thinned out, ultimately leaving from three to five plants in a pot. The seeds will germinate well outside, the main thing being to see that the soil does not get saturated in the event of heavy rains, as an excess of water is very injurious to Mignonette in any stage of pot culture. In every way good,

and hoaxed until it is time to clear the flower-beds generally, and then they do not form new roots freely, as the dull, cold days have come. Hundreds of plants damp off wholesale in the depth of winter. In August the number of plants required should be selected and all flowers cut off. In a fortnight's time young shoots will again grow; then lift the plants carefully with earth attached to the roots and plant them in boxes which are 4 inches deep and large enough to contain one dozen or two dozen plants when put in 4 inches apart each way. Use a nice gritty compost and give water directly the plants are put in, but be careful not to over-water afterwards. Keep the boxes in a cool frame very freely ventilated. Guard against damp and frost through the late autumn and winter. A shelf in a warm greenhouse is an ideal place for them. In spring cuttings will be plentiful. B.

PREPARING LOBELIA PLANTS FOR WINTER.

WHERE it is intended to winter plants instead of rooting cuttings, the former must be duly prepared, else they will die during the winter months. The reason why so much Lobelia is lost in winter is because the plants are not lifted

GARDENING OF THE WEEK.

FOR SOUTHERN GARDENS.

The Flower Garden.

Bedding Plants.—These should by this date be at their best, and between now and the end of the month a supply of cuttings should be obtained for propagation and next year's requirements. A few early cuttings of Geraniums can be obtained without disfiguring the beds if a little care is exercised. Select well-ripened shoots. They will root easily, and may be transferred to frames towards the end of next month. The lesser-growing and more tender subjects, such as Lobelias, Heliotropes, Iresines and Alternantheras, will be best inserted in pots a little later, when I hope to refer to them.

Pansies.—Seeds of these may now be sown in boxes or pans of a suitable size, filled with a sandy open compost of fine soil, stood in a cold frame and kept shaded until germination takes place. As soon as the seedlings are large enough, prick them out into beds or borders, having first well prepared the ground and broken the surface down to a fine tilth. Keep the young plants watered as necessary, and the soil around them frequently stirred with the Dutch hoe.

The Rock Garden.

Taking Cuttings.—The present month is the best time for increasing by means of cuttings many of the shrubs of dwarf habit so eminently suited to the rock garden. Select young growths, firmly insert them in a bed of fine sandy soil in a frame or pots filled with a similar compost, and keep them shaded from bright sun and watered and damped as necessary.

Shrubs for Rock Garden.—A few that may be increased in this manner are the Cistuses in variety, also Helianthemums, Olearia macrodonta, O. stellulata and O. myrsinoides, Hypericum empetriforme, H. undulatum, H. olympicum, Cotoneaster humifusa, Caryopteris Mastacanthus, Perowskia atriplicifolia, Santolina Chamæcyparissus, Othonnopsis cheirifolia (of sub-shrubby habit) and several varieties of Ceanothus.

Daphne Cneorum, the most beautiful of all the Daphnes, is best increased by layering, as are also the smaller-growing Berberises, such as B. Fremontii.

Taking Offsets.—To have a few reserve plants in case of any injury happening to those planted out, many of the Saxifrages, Sedums and Sempervivums may be propagated by potting up a few offsets in a compost of loamy soil, made porous by the addition of some coarse grit or lime rubble, and stood or plunged in ashes in an open frame, lightly shading for a few days from bright sunshine. Well water in, and afterwards damp over with a fine-rosed can and expose to plenty of air and sunlight.

Fruits Under Glass.

Peaches.—Earliest-forced Peaches and Nectarines in pots will be much benefited by removing them out of doors to a fairly sheltered spot, so that the wood may become thoroughly matured. Make well secure against winds, and keep the plants supplied with water and vigorous syringings of the foliage to maintain it in a healthy condition. The same remarks apply equally to pot Figs.

Figs.—Late Figs in pots must be kept well supplied with water at the roots, and will need considerable supplies of nourishment to assist them to fruit. The growths must be stopped and thinned, especially weak shoots, and those with large foliage particularly must not be allowed to become overcrowded. Young plants that were raised from cuttings this season should have every inducement given them to make nice plants.

Autumn-fruiting Strawberries.—These are well worth cultivating in pots for supplying dishes of exquisitely-flavoured fruit in the autumn. Until the plants are required indoors, the surroundings should be kept moist by frequent dampings, the plants kept well supplied with water and some stimulant occasionally given. The flower-trusses should be removed as they begin to set until required, also any runners and decayed leaves. If the soil on the surface becomes hard, aerate with a pointed stick. St. Antoine de Padoue is the best variety with which I am acquainted.

Plants Under Glass.

Winter-flowering Carnations.—The young plants, whether growing in pits, houses or stood out of doors, must not be neglected, and attention must be regularly paid to the staking and tying of the growths. The latter I prefer to loop up singly with neat twisted strands of raffia. Give a sprinkling of Carnation manure when rooting freely, and vary other stimulants once a week. It is well to have the plants so that protection can be given them from heavy rains; but on warm days towards evening the plants appreciate a dewing over of the foliage and a good damping down of their surroundings.

The Orchid-Houses.

Ventilating.—Throughout the summer months the majority of the occupants will benefit by a free circulation of air, and, of course, the cooler-growing section can hardly be overdone, combined with heavy shading, which should be removed, however, when the sun has gone off the house. Plenty of damping of the floors and moistening the stages and between the pots will be beneficial, as will also sprayings overhead, especially to Odontoglossums. Plants that are growing freely will in most cases take plenty of water at the roots, and those growing in baskets or perforated pans should be immersed in a pail of water.

The Shrubberies.

Buddleia variabilis.—This shrub is now making a fine display. As the name implies, there is considerable variation both in the size and colour of the flower-trusses and also the time of flowering. They are quite hardy, free growers and ought to be included in all collections. The plants may be propagated by cuttings of the young shoots or division of the roots in winter.

E. BECKETT, V.M.H.

Aldenham House Gardens, Elstree, Herts.

FOR NORTHERN GARDENS.

The Flower Garden.

Narcissus.—If at all possible, new plantations of Narcissus should be made without delay. In naturally dry soils a fair proportion of rotted manure should be deeply incorporated with the soil and, after planting, a layer of the same material and soot may be spread over the entire surface. It becomes well mixed by means of the hoe, which will occasionally be needed to surface-stir the beds to kill seedling weeds.

Colchicums.—These, too, should be transplanted if not already done. Perhaps the finest of the autumnal species is speciosum album. The plants make growth subsequent to flowering, which those unacquainted with this habit should note.

Belladonna Lily.—Clean all weeds from about established plants and stir the surface soil round about them. If the soil is dry, which it usually is when the plants are established near the base of sunny walls, a soaking of water should be applied, which will enable the flower-spikes to come all the stronger.

The Rock Garden.

Crocuses.—If any autumn-flowering kinds are to be planted, it should be done at once. Speciosum, which is an exceedingly lovely and inexpensive kind, flowers in September, so that there is not much time to delay. They are best when established under some low-growing creeping alpine plants, such as Saxifrages or Hutchinsia alpina. The common Saffron Crocus is also lovely, but is apt to die out or to abstain from flowering.

Dianthus.—Some of the earlier-flowering kinds will be seeding, and, unless seeds are wanted, it will conduce considerably to the appearance of the rockery to remove the stems. This is easiest done where the clumps are extended by means of a pair of sheep-shears or small, very sharp hedge-shears. Cuttings of some of the Mule Pinks will strike root if not allowed to ever get dry till rooted.

Campanulas.—The rather rough-habited turbinata and carpatica and varieties are apt to overstep the limits when in flower. The effects of this tendency are easily counteracted by pulling away pieces from underneath the plants, the upper portions meanwhile falling down but covering less space.

The Fruit Garden.

Removing Sprays.—It is usual for Pears, Plums, and Apples to produce weakly growths from the cut-backs of the summer pruning. These are of no manner of use to the trees, and should be removed as opportunity presents itself, not cutting them, but removing them entirely. The sooner this is done, the easier they are to break off.

Apricots.—The earliest fruits of these will be ripe or ripening, but much depends on the weather. I have known it to be September before any ripe fruits could be gathered. For preserving, the fruits are better if not quite ripe. When fully ripe, the skins are not so easy to peel clean. Where birds are preserved, it is imperative to place berringtons in front of the trees, and it may be added that the only way to circumvent wasps once they discover them is to pick the fruit at short intervals and before it is quite ripe, keeping it till ready in a cool fruit-room.

Peaches.—All the trees should be gone over and the new shoots laid in finally before the crops ripen. It is essential to expose the fruits to the light, and this more especially as regards late varieties. Some successful growers soak the borders with manure-water in order to increase the size of the fruits. There is always a danger of retarding the ripening of the wood where this practice is followed, but it indubitably is the means of the production of high-quality fruits.

Shrubs.

Deutzias.—The late-flowering varieties of the scabra section have been very fine, and now that the flowers are past, these shoots may be cut back to allow greater space for those of the present year, which will be the flowering shoots of next year. Prune so that flowers may be produced from the base of the plants instead of from the upper parts only, which they have a tendency to do unless corrected by judicious pruning.

Spiræas.—The good effect of hard pruning in spring will now be seen in the beautiful condition of the japonica and callosa sections, which are covered with bloom. The present is the best time to prune ariæfolia, which has just finished flowering. Very slight pruning is needed; merely a shoot here and there to ease the plants in places which are overcrowded with shoots. Lindleyana may also be seen to.

The Vegetable Garden.

Leeks.—If some soil be drawn up to the rows of the maincrop Leeks, it will serve to lengthen the part blanched, which by many is the only part used.

French Beans will be generally far enough advanced to necessitate the picking off of the too advanced pods, which are extremely hurtful to the cropping qualities of the plant if left to mature. Those for late cropping in frames should be thinned to at least 12 inches apart.

Lettuces and Endive.—Where these are in daily request, transplant at short intervals from the seedling lines in any ground as it becomes vacant. Lettuce does best in a well-worked friable soil. Endive is less exacting in its requirements, and a rather poor soil is to be preferred for it. In such it undergoes the exigencies of our winter climate better than if grown rankly.

The Plant-Houses.

Narcissus.—The potting and boxing of these bulbs should be finished forthwith. They succeed best in not too small pots, and in none do they ask for much drainage, the space which would be occupied therewith being more advantageously supplied with the roughest of the compost made rather firm.

Carnations.—Those border varieties which have been grown and flowered in pots should now be turned out and planted on a border and the grass layered. The rule invariably is that such layers provide the healthiest plants, and some kinds, e.g., Lady Hermione, can in some gardens be kept only by this treatment.

Schizanthus.—There is no special hurry to sow seeds, the main sowing being better deferred for some weeks. Those who do sow now will find the practice of sowing in small pots, afterwards thinning the seedlings to one in each pot, a very satisfactory way of starting these.

R. P. BROTHERSTON,

Tynningham, Prestonkirk, N.B.

NEW AND RARE PLANTS.

AWARDS OF MERIT.

Lysimachia Henryii.—A recent introduction from China, a plant of sterling merit and a useful addition to the genus. As a summer-flowering and free-flowering plant of low growth it will be welcomed by all hardy plant-lovers. Not more than 6 inches or 8 inches in height, the trailing or sub-erect branches are terminated by a cluster of clear yellow flowers arranged in a leafy setting. It is perhaps the only member of its race worthy of inclusion in the good rock garden, where it will be most at home in cool or moist places in a spongy soil. Several admirably-flowered examples were shown by Mr. M. Prichard, Christchurch, Hants.

Gladiolus Crown Jewel.—This is apparently a strong-growing variety of salmony pink colouring, with yellow blotch on the lower petal. From Messrs. J. Kelway and Son, Langport.

Begonia Decorator.—Judged by the drooping habit of its flowers, this variety should prove of considerable value for basket-work or for any position where a trailing plant is desired. The example shown was grown as a pyramid, and was highly attractive. The scarlet flowers are of medium size. Exhibited by Messrs. Cannell and Sons, Swanley.

Rhododendron Clorinda.—This is one of the javanico-jasminiflorum hybrids, and was raised from a cross between jasminiflorum carminatum and Minerva. The flowers, which are of a rich rose colour, shading to scarlet at the margins of the petals, are produced in a large and handsome truss. From Messrs. James Veitch and Sons, Limited, Chelsea.

Clethra arborea.—It may seem strange that any plant known to cultivators or botanists for something like a century and a-quarter should not have had its merits recognised long ago. Such, however, appears to be the case, the plant having been introduced in 1784 from Madeira. Usually cultivated in inland gardens as a greenhouse shrub, it is sufficiently hardy in the open in the South and South-West to warrant general cultivation in that way, and grows into a handsome, freely-flowered bush several feet in height. Thus seen it is a plant of ornament and beauty, the pure white fringed flowers depending from the under sides of the horizontally-disposed branches with great freedom. As a pot plant for the cool greenhouse or conservatory it is worthy of general notice. From Messrs. Stuart Low and Co., Enfield.

Eschscholtzia Mikado caniculata.—The most brilliant colour in Eschscholtzias we have seen, and a novelty of considerable merit. The colour is intense crimson scarlet, with more than a suspicion of orange infused therein. The petals are distinctly frilled or pleated, distinction being thus added to a brilliant flower. From Mr. W. H. Gardiner, Mill Street, St. Osyth.

Rose Danae.—A new Polyantha variety of distinction and merit. The colour tone is an approach to that of a pale Lady Hillingdon, the form of the flower being slightly cupped. Judging from the examples shown, the new-comer should prove an acquisition. Exhibited by the Rev. J. H. Pemberton, Havering-atte-Bower.

Astilbe simplicifolia.—A new species of dainty grace and elegance, and a miniature withal. Six inches or so high and of a spreading, tufted habit of growth, the hard-textured leaves are entire, 2 inches or more long, tapering to a needle-point,

and with copiously and acutely toothed margins. The minute blossoms are pure white, and are produced in a spray-like inflorescence which is disposed horizontally. It is quite an acquisition to hardy plants, and of undoubted hardiness. It is from Japan. Exhibited by Mr. G. Reuthe, Keston, Kent.

Hæmanthus Andromeda.—We have no information concerning the parentage of this showy form, which in general aspect approximates to a pale-coloured H. Katherinæ. The colour is pale orange scarlet. Several fine plants were shown, and all proportionately handsome in leaf and flower. Exhibited by Mr. Cory, St. Nicholas, Cardiff.

NEW POTATOES.

The following awards were made to new Potatoes as the result of trials held at Wisley: A first-class certificate was awarded to Messrs. Smith and Sons, 18, Market Street, Aberdeen, for the variety Whitehill Seedling. Awards of merit were granted to Messrs. Barr and Sons, Covent Garden, for Imperial Beauty; and to Mr. W. E. Sands, Hillsborough, County Down, Ireland, for the varieties Irish Gem and King George V.

The foregoing awards were made at the fortnightly meeting of the Royal Horticultural Society held on July 30.

CLIMBING ROSES IN AN ISLAND GARDEN.

SOME Roses trained on walls have grown and flowered profusely. Among the best are J. B. Clark. This Rose the writer has never seen in finer condition. The flowers were exceptionally large and the colour intense deep scarlet, with its shade of blackish crimson, and the petals carrying a rich bloom like a Plum. This Rose is growing on an east wall, but is sheltered from the full force of the east winds by another wall running parallel on the opposite side of a garden walk. American Pillar is now, at the time of writing, one mass of flowers, very healthy and producing strong young shoots. The Wallflower has flowered well, although not growing so strongly as one would like to see it. Climbing Kaiserin Augusta Victoria has produced an abundance of its immense flowers. Near to the latter is the pretty little Rose Fairy, a Polyantha Rose which is happily named, not a strong grower, but a perpetual bloomer. Its small white flowers, with yellow anthers, are very attractive. Mrs. F. W. Flight has produced an abundance of its bright pink semi-double flowers. Rubin has flowered freely for several weeks. The dark foliage of this variety adds much to its attractiveness. White Dorothy Perkins on an east wall is commencing to flower, but this variety, with its pink progenitor, is not so free-flowering here as one generally expects to see them. Blush Rambler is very good. Queen Alexandra is one of the best growers, although flowering somewhat sparsely. Una grows very vigorously, and is one of the best we have. Excelsa on a west wall grows and flowers freely. Mme. Alfred Carrière, planted this spring in an exposed position, has made some good strong shoots which look promising for a wealth of bloom next season. Varieties which have made abundance of healthy growth, but have not flowered as freely as one would like to see them, are Thalia, Goldfinch, Gloire de Dijon, Chesbunt Hybrid, Aglaia and Grüss an Teplitz. Bouquet

d'Or should be mentioned as the best early-flowering variety we have on a west wall. Among Climbing Hybrid Teas, in addition to Kaiserin Augusta Victoria, already mentioned, Climbing La France, Climbing Mrs. W. J. Grant and Climbing Caroline Testout are excellent. William Allen Richardson lost a good many shoots during the early spring. Dundee Rambler is not growing with its usual vigour. Possibly it may do so when it gets thoroughly established. The Garland and Jersey Beauty, planted this spring, are growing freely. Rêve d'Or is making only moderate growth in an exposed place, but where growing in a sheltered position it is very satisfactory. Crimson Rambler and Tausendschön are both badly affected by mildew and are not at all good here. The possible reason is that they do not get sufficient sun. China Roses in the borders are very healthy. Conspicuous for freedom of growth and flower is the variety Queen Mab. The Penzance Briars do not suffer to any extent from the violence of the strong south-westerly gales which are so frequently experienced.

COLIN RUSE.

Lambay Island, Rush, County Dublin.

ANSWERS TO CORRESPONDENTS.

RULES FOR CORRESPONDENTS.

QUESTIONS AND ANSWERS.—The Editor intends to make THE GARDEN helpful to all readers who desire assistance, no matter what the branch of gardening may be, and with that object will make a special feature of the "Answers to Correspondents" columns. All communications should be clearly and concisely written on one side of the paper only, and addressed to the EDITOR OF THE GARDEN, 20, Tavistock Street, Covent Garden, London, W.C. The name and address of the sender are required in addition to any designation he may desire to be used in the paper. When more than one query is sent, each should be on a separate piece of paper. Plants for naming should be clearly numbered and securely packed in damp grass or moss, not cotton-wool, and flowering shoots, where possible, should be sent. It is useless to send small scraps that are not characteristic of the plant. Letters on business should be sent to the PUBLISHER.

FLOWER GARDEN.

CARNATIONS NOT FLOWERING (Beatrice).—Failing a sight of the plants referred to, we can only suggest that the plants were either small or undeveloped specimens, or that, if of good size, the Carnation maggot has eaten out the hearts during winter. You might prove this or otherwise by a close inspection of the central parts of the plants. Their business, particularly if the growths be small, points to an attack of the maggot. The leaves may have fallen from the Rose because of extreme root dryness or a bad attack of red spider. Damp in a year like the present, the spring of which has been remarkably dry, is not likely to be the cause. We presume the plants have a fair depth of good soil, but you say nothing about this or the position they occupy, and either or both may have an important bearing on the point. The Gladioli would be far better lifted, rested and replanted, and will give more satisfactory results if so treated. Lift the early ones in August, and replant in October in a fresh spot. Take up the late-flowering sorts late in September or in October, store them in some dry, frost-proof place, and replant them in March. The early ones you could still mulch with impunity.

PLANTING NEWLY-MADE ROCK GARDEN (Veritas).—Without knowledge of the preparation made for the reception of the plants, it would be hazardous to give you a list for your somewhat extensive arrangement. So many things go to make success in such matters—environment, the average size of the pocket, space at the disposal of the planter and, not least, some knowledge of the plants themselves to ensure their rightful disposal. We will give you a list of plants with pleasure, but in so doing would like to feel that we were giving you the best for the purpose. In a rock garden of the extent named and of such varying height there should be room for a great variety of things—dwarf conifers, trailing shrubs and alpines—not of the expensive order, but of a type calculated to make it interesting over a prolonged period. As it is only just completed, there is no immediate occasion for planting it, and a few weeks hence, when the soil has settled down, would be better. Would you, therefore, in the meantime send a few further particulars, especially concerning the soil depth and the provision made for

the plants, with some idea of its width and its steepness or otherwise? The case is really one for advice on the spot, and an expert's fee might be saved many times over and much future disappointment avoided were this view adopted.

ARUM (A. K.).—The specimen you send is the common Dragon (*Dracunculus vulgaris*), also known as *Arum Dracunculus*. It is an interesting and curious plant, growing wild in South Europe. You may not think the flower very showy, but many people consider the plant worth growing for the foliage and mottled stems. *D. vulgaris* thrives in most soils, but prefers a rich, moist soil in a half-shady position. The plants are often associated with hardy Ferns. Propagation is effected by division of the roots in spring just when new growth is commencing.

PYRETHRUMS AND IRISES (W. W.).—Some good double-flowered Pyrethrums are *Ne Plus Ultra*, bluish pink; *Captain Nares* and *J. N. Twedy*, crimson; *Pericles*, yellowish; *Carl Vogt* and *Aphrodite*, pure white; *Queen Mary* (new), pale pink; *Auribundum plenum*, rose; and *Solfaterra*, pale primrose. Your enquiry concerning Irises in June is a little vague, as in that month the entire range of Flag or German Irises, and Spanish Irises, which are bulbous, are then in bloom. Apart from these there are a great variety of distinct forms. A good collection of Flag Irises should include *aurea*, golden; *Mme. Chereau*, violet and white; *Queen of May*, rosy lilac; *Dr. Bernice*, smoke and bronze; *palida*, and *p. dalmatica*, delightful shades of mauve; *Princess of Wales*, white; *atropurpurea*, dark purple; and *Mrs. Charles Darwin*, one of the best of the whites. All Irises are good for cutting, and if this selection does not meet your requirements, please give us a more definite idea of your needs. We cannot say which is the largest *Ranunculus*; everything depends on the size of the tuber and the cultivation afforded to individual plants or groups.

REMOVING PLANTS IN SEPTEMBER (H. A. S.).—Though such things as *Michaelmas Daisies*, and in a lesser degree the hardy *Fuchsia* and *Anemone*, would be in flower at the time, none of these would be inconvenienced greatly by the removal so far as future success is concerned. The better way to deal with them would be to lift the clumps, shake off a good deal of the soil, and pack closely in egg-boxes or anything of convenient size. Most of the plants will, if large, repay for dividing. The *Pæonies* must certainly not be replanted intact if big, unless failure is courted, while *Iris stylosa* should be freely divided and replanted in stony or gravelly soil, or that charged with old mortar refuse, in the hottest position you can command. In all the circumstances your better plan, seeing that the garden to which you are going is unoccupied, would be to obtain permission to enter and prepare in advance, and with permission to move the plants these could be lifted piecemeal. The overgrown shrubs will require some attention, but only a person on the spot could decide this. The sketch you submit appears to be a quite convenient one for the place, that is, so far as making the most of the ground is concerned, while the side borders might be devoted to herbaceous perennials, *Roses* and other flowers. The new garden should be thoroughly trenched and manured, and coarse weeds removed and burnt. "The Culture of Vegetables and Flowers," published at 5s. by Messrs. Sutton and Sons, Reading, should prove helpful to you, seeing that it treats of all-the-year-round gardening. Apart from this, the columns of THE GARDEN weekly contain much useful information concerning these and other departments of gardening. "Root and Stem Vegetables," by Alexander Dean, price 1s. 6d., should also prove of service. It may be had of the Publisher, 41, Wellington Street, Covent Garden, W.C.

TREES AND SHRUBS.

EUONYMUS (M. O. A.).—The *Euonymus* is attacked by a scale insect, a species of *Lecanium*. The brown scale protects numbers of pinkish eggs, and little can be done to destroy these; but watch should be kept, and as soon as the eggs hatch, the bush should be sprayed with paraffin emulsion or with a nicotine preparation. In the case of deciduous bushes, such as *Currants* and *Gooseberries*, a useful measure is spraying with an alkali wash in winter, but this must on no account be used on bushes which retain their leaves.

LAVENDER, ROSEMARY AND LEMON VERBENA (H. E. B.).—September is a good time to plant *Lavender* and *Rosemary*. Your treatment of the *Lemon Verbena* (*Lippia citriodora*) is that usually followed with success. Why a plant in apparently good health and favourable position should die for no evident reason puzzles the greatest horticultural experts at times, yet such a thing does happen in almost every garden from time to time. All we can suggest is to plant a young *Lemon Verbena* out again next spring, when probably you will be more successful. Plants against a wall sometimes get dry, even during showery weather, owing to rain heating the other way.

LILAC BUSHES UNSATISFACTORY (G. G. N.).—The exceptionally dry spring is, no doubt, the cause of your bushes failing after replanting, for though you may have provided plenty of water at the roots, overhead watering is necessary as well. It is advisable when replanting trees and shrubs of any size to reduce the growths to compensate somewhat the disturbing of the roots, which, naturally, take some little time to become established. Your best procedure now will be to cut down the bushes to one-third their height, mulch with some old decayed manure, water the roots during dry weather, and syringe or damp over the top morning and night to induce the production of young shoots from the wood.

ARBUTUS AND OTHER SHRUBS (R. S. D.).—Unless *Arbutus Unedo* is outgrowing its position, it requires no pruning. If you wish to reduce its size, cut it back in April. *Diplopappus chrysocephalus* may be cut back in March or April. *Perowskia atriplicifolia* may be pruned fairly hard in March. The dwarf kinds of *Philadelphus*, such as *P. Lemoini*, should have all flowering wood cut away as soon as the flowers are over. The tall-growing kinds require very little pruning. An occasional thinning out may be given after flowering. The late-flowering kinds of *Tamarix* may be cut back in spring; the early-flowering kinds after the flowers have faded. *Viburnum rhytidophyllum* requires very little pruning. If the branches are becoming ragged, however, they may be topped any time during late spring or early summer. *Weigelas* may be thinned out as soon as the flowers are over. Thinning is not required every year, and when it is done it should take the form of removing the older branches. Two of the best deciduous *Barberries* are *Berberis vulgaris* and *B. Thunbergii*. The two best evergreen kinds are *B. stenophylla* and *B. Darwini*. Two of the best dark red *Lilacs* are *Charles X.* and *Souvenir de Louis Spaeth*. Two good white ones are *Syringa vulgaris alba grandiflora* and *Marie Lecraye*. A good tall-growing *Philadelphus* is *P. grandiflorus* variety *floribundus*.

THE GREENHOUSE.

CARNATIONS (T. B.).—The three classes of Carnations concerning which you enquire are propagated in different ways—the *Perpetual-flowering* by cuttings in the early part of the year, the *border varieties* by layering in the open ground as soon as the flowers are past, and the *Malmaisons* by layering under glass in the month of July.

FERN-HOUSE AND FLOWERS (K. Q.).—An exceedingly difficult question, and possibly you may think our answer a disappointing one, for we do not really know of any flowers good for cutting that may be grown in the interstices of the walls of a Fern-house. The atmospheric moisture suitable for the Ferns would also be beneficial to the red and white *Lapagerias*, and you might perhaps with advantage train them to the roof. In the warmer house, pretty foliage subjects, such as *Begonias*, *Panicum variegatum*, *Pittonias*, *Episcia fulvida* and others of this class, may be grown, but the flowers are of minor account, and in no case are they available for cutting.

PRIMULAS (B. S. R.).—*Primula cockburniana* generally succumbs after flowering, because it is only a biennial. It seeds freely. Seed should be sown soon after it is ripe; then a good stock is kept up. Although *Primula japonica* hybrids are usually classed as perennials, the finest display is procured by growing on a stock of young plants. When the plants get old and have flowered profusely, they often decay at the base instead of forming fresh crowns, especially when we get a lot of rain immediately after. Another cause is too rich a soil or planting them too deeply. One piece you sent would have probably grown if it had been potted up and kept shaded in a close frame for a few weeks. Regarding those left in the ground, we should take up those affected, divide into single crowns, and lightly dust the base with lime or powdered charcoal. Place each crown in a small pot and, when established, plant out in a fresh piece of ground. You will probably lose some, but as *P. japonica* produces seed in abundance, we should certainly save some from the best varieties and sow it as soon as ripe, when germination takes place in a short time. In two years you would have very strong-flowering specimens.

VARIOUS QUERIES (C. B. A.).—The three *Begonias*, namely, *Gloire de Sceaux*, *corallina* and *President Carnot*, will all conform to the same mode of treatment. They can be readily struck from cuttings of the young growing shoots taken during the spring months, inserted into pots of light, sandy soil, and placed in a close propagating-case with a gentle bottom-heat. It is, however, now too late to think of propagating from your old plants this season, but they may now be re-potted. A mixture of two-thirds of loam to one-third of leaf-mould and a good sprinkling of silver sand will suit them well. As much of the old soil as possible should be removed when re-potting, and care must be taken not to use pots too large. Although these *Begonias* will, during summer, thrive in the greenhouse, they will be all the better, if you have a structure available, in the temperature of an intermediate house. In order to induce them to flower during the winter, the temperature of the house in which they are grown should at that season not be allowed to fall below 50°, and it may run up 10° to 15° during the day. The *Gesneras* which are resting should be started into growth without delay. To do this they may be shaken quite clear of the old soil and re-potted in small pots in a mixture of equal parts of loam and leaf-mould, with a liberal sprinkling of silver sand. After this they need to be placed in a fairly snug structure kept at a temperature above that of an ordinary greenhouse. Care must be taken not to overwater till growth commences, when more can be given. In the autumn they require a good light position in a house where a temperature of 55° to 70° is maintained. They will need to be shaded till the sun loses power, and at no time should the rich velvety leaves be syringed. As soon as the plants are sufficiently advanced, they must be shifted from the small pots in which they were started into larger ones, 5-inch pots being very suitable for this shift. If you wish your *Perpetual-flowering Carnations* to flower during the winter months, it will not be a satisfactory arrangement to grow them and the *Malmaison* varieties together. The members of the *Malmaison* group should, during the winter, be kept as cool as possible consistent with their being quite safe from frost. A minimum night temperature of 45° in mild weather, or a little higher

during severe frost, will be very favourable to *Malmaison Carnations*; whereas, in order to obtain flowers of the *Perpetual-flowering* varieties, the house must be kept nearly ten degrees warmer. You might obtain fairly good results by maintaining a temperature between the two. The plants will not require shading. Something might be done by placing the *Malmaisons* at the coolest end of the house.

ROSE GARDEN.

INJURY TO ROSE FOLIAGE (Blanche Branston).—The foliage you send has been injured by the *Rose slug-worm*. If you examine some of the leaves, you will find a small greenish-looking maggot on the under side of the foliage. It can easily be killed by spraying with nicotine wash or *Hellebore* wash. We have given a recipe for both in a recent number of THE GARDEN. It would be well to have the surface-soil removed to a depth of about an inch next winter, and either bury it deeply or burn it.

ROSE FOLIAGE BLIGHTED (Sir P. G.).—The fungus attacking your *Roses* is that known as *red rust* or *orange fungus*. Very few of the *Hybrid Perpetual* *Roses* escape this fungus, especially at this time of the year, and we do not think you need be alarmed about it, as it is often disseminated from the wild *Roses*; but it would be well to spray the trees with *Bordeaux* mixture at once. Remove the worst leaves and burn them, and in winter collect all fallen leaves and also burn them.

BASIC SLAG TO ESTABLISHED ROSES (E. K. B.).—This excellent fertiliser is very beneficial to established *Roses*. It is very slow in its action, so needs to be applied in the autumn. A dressing at the rate of 6oz. per square yard of surface would be about right. This should be forked or hoed into the soil, and may be applied at the same time as the annual dressing of farmyard manure. Try to secure some of the best manure you can from a farm where cows and pigs are constantly treading it about. This is far better than the strawy material that too often passes muster as manure.

KITCHEN GARDEN.

BLACK CATERPILLARS DESTROYING ASPARAGUS (L. L.).—Spray the foliage of your *Asparagus* with the wash given below, and you will find the caterpillars will disappear. If they do not after one application, they will after two. The wash should be applied in a fine spray with the syringe or garden pump, and at once. *Asparagus* is now out of season, and you should cease cutting, or the plants will suffer injury another year. In spraying, see that every part of the plant is well wetted. Arsenate of soda (dry), 2oz.; acetate of lead, 7oz.; water, 10 gallons. Dissolve together in water and well stir, adding 1lb. of treacle.

FRUIT GARDEN.

PEACH FRUIT DROPPING (E. Hopkins).—The cause of the fruit dropping is, no doubt, the defective stoning of the fruit of which you speak. It is a malady of the Peach termed "stone-splitting" or "rotting." This is generally attributed to the defective fertilisation of the blossom when the tree is in bloom. Next year be careful to fertilise every blossom on your tree, and that with pollen from other trees in bloom at the time, if possible; if not, with the tree's own pollen.

INJURY TO FRUIT TREES (Barnside).—Many gardens have suffered greatly this spring from late frosts, drying winds and long spells without rain, with the result that the tender foliage of Apples has suffered severely. This is sometimes seen in spots, brown or reddish, on the leaf, sometimes in the margin of the leaves becoming affected, often in the whole leaf being browned and "burnt." Apples with tender foliage, like *Cox's Orange Pippin* and similar varieties, are usually the first to suffer, and suffer most severely. Spraying with half-strength *Bordeaux* mixture will help to protect the foliage, even when weakened by bad weather conditions, from attacks by fungi, for some common fungi, like *Cladosporium herbarum*, are apt to attack such weakened leaves; but unless shelter can be given, in certain seasons *Cox's Orange* and similar Apples are almost certain to suffer.

GRAPES MILDEWED (Mrs. L. L.).—There is no manner of doubt as to what your *Grapes* and *Vines* are suffering from, namely, a severe attack of mildew. The cause of the attack, no doubt, is due to the prevalence of so much cold and wet weather, and especially to the night temperature ranging so low. Had a little fire-heat been applied to the pipes at night on the occasions of cold and wet nights, the probability is that the *Vines* would have been saved from attack. Next year you must try to bear this in mind. It is only a very little heat which is required, just enough to slightly warm the pipes, in order to create a movement and circulation of air. With this small amount of heat at night in cold, wet weather, a very little air must be admitted back and front, so that a circulation of air is maintained. Two of the bunches sent are so badly affected as to be useless, and should be burnt; but there is one which we should leave, and all others like it, as they may yet develop into useful *Grapes*. After all the badly-affected bunches are cut off, dredge those remaining thickly with flowers of sulphur (all the *Vine* leaves as well), let the sulphur remain on for thirty-six hours, shading the house slightly during this time, and then syringe the sulphur off with clear rain-water only. If the dredging is effectually done, the mildew will be killed, and as a consequence the *Vines* will greatly improve in health.

EDITORIAL NOTICES.

Every department of horticulture is represented in **THE GARDEN**, and the Editor invites readers to send in questions relating to matters upon which they wish expert advice.

The Editor welcomes photographs, articles and notes, but he will not be responsible for their safe return. All reasonable care, however, will be taken, and where stamps are enclosed, he will endeavour to return non-accepted contributions.

As regards photographs, if payment be desired, the Editor asks that the price required for reproduction be plainly stated. It must be distinctly understood that only the actual photographer or owner of the copyright will be treated with.

The Editor will not be responsible for the return of artistic or literary contributions which he may not be able to use, and the receipt of a proof must not be taken as evidence that an article is accepted. Publication in **THE GARDEN** will alone be recognised as acceptance.

Offices: 20, Tavistock Street, Covent Garden, W.C.

NOTES OF THE WEEK.

The Nut Crop in Kent.—We understand that the Nut crop in Kent this season is the heaviest that has been known for a great many years. Contract prices that are now being arranged are very much lower than usual; but it remains to be seen whether the consumer will obtain Kentish Cobs and Filberts much cheaper than in past years.

Snapdragons and the Rock Garden.—The value of Antirrhinums as plants for the rock garden does not appear to be sufficiently recognised. In the beautiful gardens of Sir Herbert Leon, Bart., at Bletchley Park there is at the present time a low rock garden planted throughout with dwarf Antirrhinums, chiefly in yellow and orange tones of colour. This novel rock garden, though simple in design, is very pleasing, and for harmonious blending of colour it would be hard to excel.

Pea Disease in France.—Those who have lost Sweet Peas in this country by the attacks of the fungus *Thielavia basicola* will be interested to learn that it has created great havoc among culinary Peas in France this year. In one centre the crop has been practically exterminated. Although it attacks culinary Peas in this country, they do not appear to be so generally affected as Sweet Peas. It is a pest for which some of our scientists would do well to give us an easily-applied and reliable remedy.

Mimulus Burnetii.—The hardy *Mimulus* appear to be enjoying the wet season, and among them the pretty *Mimulus Burnetii* has been, and is still, very good indeed. It is a hybrid between *M. luteus* and *M. cupreus*, and partakes of the characters of both parents. It has all the hardness of *M. luteus*, with much of the colour of *M. cupreus* and a slightly taller habit than that species. It was raised by Dr. Burnet of Aberdeen. It is perfectly hardy, but dislikes drought, and may be lost in a very dry soil unless kept supplied with moisture.

The Indian Rice.—There are few more decorative water-side plants than this, for it grows to a height of 8 feet or 10 feet, has long, graceful leaves and good-sized, plume-like inflorescences, which are showy for a period of several weeks. Moreover, the plant commands attention by reason of its distinct appearance from the time the foliage is well developed about the end of June until the seeds are ripe towards the end of September. The Indian Rice is known to scientists as *Zizania aquatica*, the common name having arisen on account of the North American Indians using the Rice-like seeds for food. The difficulty of importing seeds in a fertile condition led to its cultivation being dropped in this country for many years. It can, however, be obtained now, and when once grown it need not be lost, providing the necessary care is taken in the collection and preservation

of the seeds. These must be collected when ripe, and either be tied in a piece of canvas and sunk in water or be placed in a vessel of water for the winter. In the latter case the water must be changed once or twice a week. Early in March the seeds must be sown in pots of loamy soil and be stood in water indoors to germinate. Grow in pots, in water, until May; then plant out permanently.

Campanula waldsteiniana.—As one of the most beautiful of alpine Bellflowers this appears almost the last word, and it is certainly one of the most desirable, if at times also a little capricious. The plant is 4 inches or so high; the greyish entire notched leaves, acutely pointed, are about an inch in length. The corollas, which on the stronger stems cluster to the extent of a dozen occasionally, are erect and of a distinct reddish violaceous blue, which, with the conspicuously white-tipped stigma of the early hours of expansion, give the plant a peculiar charm of its own. If given a rather free root-run in a crevice in grit and loam, it will not fail to please. It comes from Hungary.

The Cobweb Plant.—It is doubtful whether the best use is made of this easily-grown alpine, *Sempervivum arachnoideum*. Too often the species and its varieties are seen in clustered masses, which afford but little room for the development of the individual rosettes, and it is just this lack of development which makes all the difference between success and failure. By isolating the rosettes—by pricking them out an inch or so apart—a good opportunity is afforded for full development, and larger and more characteristic groups are the result. In gritty soil or loam and old mortar the plant does well. It is alike good for vertical or horizontal fissures in rockwork, its downy leaves being very attractive.

The Transvaal Daisy.—An interesting and attractive feature is provided at Kew at the present time by a border of this showy South African Composite, *Gerbera Jamesonii*. The border in question is situated at the foot of a wall on the south side of a range of glass-houses, and is thus well drained and warm. That it is peculiarly suited to the plants is evident from their luxurious growth and free-flowering character, and people who are desirous of trying the plant could not do better than copy as nearly as possible the conditions which exist at Kew. On its introduction G. Jamesonii impressed horticulturists favourably with its showy flowers, yet a considerable time elapsed before its cultural requirements came to be fully understood. The hybrids raised from it by Mr. Lynch of Cambridge a few years ago perhaps did more than anything else to popularise it, and both type and hybrids are now to be found in many gardens. Not only as border plants are the *Gerberas* valuable, but few subjects are more charming for cutting for house decoration.

CORRESPONDENCE.

(The Editor is not responsible for the opinions expressed by correspondents.)

Pruning the French Honeysuckle.—Mr. S. Arnott, whose note on this subject appeared on page 387, August 3, points out that he meant *Hedysarum multijugum* and not *H. coronarium*. This name was originally given in his copy, and was inadvertently deleted to make the paragraph fit in the page.

Exhibiting Carnations.—At the National Carnation Show held on July 23 last, the following remark was made in my hearing by one lady to another about some exhibits of dressed fancy flowers: "Oh, they are no criteria to go by; they don't grow like that." And they passed on to notice those without the "trimmings."—C. TURNER, *Highgate*.

Roses with Bad Habits.—I won the medal for the best Hybrid Tea Rose at the National Rose Society's show at Ulverston in 1911, the autumn show in 1911 and the Botanic Show in 1912 with *Horace Vernet*, which "P." includes in his article on "Roses with Bad Habits." These blooms were all from cut-backs, one of them a five year old plant. I find *Horace Vernet* one of the best as a cut-back.—G. SPEIGHT, *Market Harborough*.

Rose J. B. Clark.—Having read "P.'s" note about this Rose on page 379, may I recount our experience with this variety, which we have had four or five years. The first two seasons it made tremendously long and strong growths, yielding scarcely any flowers. Then we took up the plant and replanted it in another bed at the other side of the Rose garden, where the position was not quite so good. Before it was replanted its roots were rather severely cut back, the top very little, while a couple of the longest shoots were kept intact and arched over to the nearest plant. Since then we have had no trouble with it not flowering. Last year and this year it has done well. Wherever this variety is making too much top and producing little or no bloom, I would recommend replanting, root-pruning and arching of long shoots as a remedy.—C. T.

Matthiola bicornis.—It is no good, Mr. Editor, I have to write. My nose has been enjoying the delicious perfume of *Matthiola bicornis*, and it says that there may be a whole lot of noses that have never smelt it; in fact, it suggests that they do not even know what sort of a thing it is. Well, it is something very cheap, which, to begin with, is a good thing. It is also something very easily grown; as a big Tulip-grower said to me this spring of Prince of Austria, it is an "any fool's plant." There is no difficulty about it. Put the seed on the ground, lightly rake it in, and Nature does the rest. I bought sixpennyworth this spring, and about mid-May, when all the foliage had died down, I sowed it all over my two blue beds of *Chionodoxas* and *Muscari*. Each is 18 feet long by 5 feet wide. It was ample to cover them entirely, and now every evening and all night long they are a mass of pale shades of purple and mauve, and a veritable active volcano of the most delicious perfume. Many an idle moment in the past fortnight have I spent in gratifying my olfactory organ, and there seems every prospect of many more being spent in a similar way.—JOSEPH JACOB. [We agree with all Mr. Jacob has written about this plant. We have also been enjoying its fragrance for weeks past.—ED.]

Early Chrysanthemums in South-West Scotland.—Among the effects of a peculiar summer such as that of 1912 has been that of dwarfing early Chrysanthemums in the South-West of Scotland, and, for that matter, other districts as well. After seeing a good many gardens where these favourite flowers are grown, and grown well, one is surprised to find how general is the dwarfed character the early Chrysanthemums have assumed this season. In a dry season, such as that of 1911, the effects of high culture were quite apparent, as the plants on well-manured soil were infinitely better than on poorly-cultivated land. This year, however, the free application of manure and the most liberal treatment have failed to form really fine plants, and many varieties which in normal years are among the tallest are this year far below the height of those of medium stature in other seasons. Rather curiously, also, old plants left in the ground which survived the winter are much more vigorous than young ones raised from cuttings as usual.—S. ARNOTT.

Judges Judged.—I am asked to express an opinion as to "whether judges of exhibits at a show may act contrary to the published rules of the society by which competition is invited." My reply to that question must be in the negative. A judge must act strictly within the *wording* of the schedule. See Paragraph 10 of the Royal Horticultural Society's "Rules for Judges," sixth edition, 1908, in which the governing term is set in italics as above for emphasis. In case of doubt, the rule goes on to say that judges should appeal to the show authorities on the question of awarding or withdrawing prizes. I did not see the Sweet Pea contest about which such differences of opinion have arisen, but after over forty years' experience in judging, I am satisfied that Mr. Jenkins is right that the judges had no power to go beyond disqualification; but—for there is a "but" in the case—the same rule of the Royal Horticultural Society above cited goes on to say that though the judges may be forced to disqualify, they may *recommend* the authorities to entertain certain proposals for meeting the case. If this was done and official sanction obtained, it would seem that the result, right or wrong, must stand, though if "A. B. Essex" is accurate in his statement regarding the "breaking of a plainly printed rule," the verdict would be *ultra vires* (beyond one's power or rights), and therefore should be quashed. It is not easy to discuss a case briefly in the absence of relative cognate facts, and as there are numbers of men of my name engaged in gardening whom I have no wish to involve in a controversy, my identity will be sufficiently clear as—JOHN WRIGHT, *V.M.H.*

—The schedule of a flower show I look upon much in the same light as the captain of a vessel looks upon his chart. It is an instrument carefully prepared (or should be) for the guidance of the committee of management, laid down by its responsible officers, but it is equally a guide, and as binding on the exhibitors and judges. Why, I have known important exhibits of fruit disqualified simply because a trivial mistake had been made of adding one more Peach or Nectarine to a dish than the number stipulated in the schedule. The schedules are studied intently and earnestly for months beforehand by exhibitors, and elaborate care is taken to conform to the letter to the conditions laid down, and any judge, in my opinion, who acts knowingly in contravention of the rules and conditions so laid down in the schedule for exhibitors to work to offends not only against the

exhibitor, but against the authors of the schedule, the managers of the show. If this were persisted in, the same end would come to the show as in the case of a vessel the captain of which disregarded his chart. The principle applies with the same force to exhibitors if they make a mistake of wrongly interpreting the schedule.—OWEN THOMAS.

—In my opinion the rules made by a committee are equally as binding on the judges as on the exhibitors, and no judge should act contrary to the published rules in the schedule.—S. T. WRIGHT, *Wisley*.

—The question of judges acting independently of, or contrary to, the rules as printed in the schedule of any society is certainly an ultra measure for any judges to take, and if allowed by any society would very soon land it in litigation. The rules printed in the schedule of any society are simply the conditions by which both exhibitors and judges are to be governed in their connections with the society, even if, as is sometimes the case, they are palpably wrong.—J. JAGUES.

—The Editor is good enough to ask me if I would care to express an opinion on this point. I should. I repeat what I said emphatically at the show—that the judges were bound by the schedule, and had no right to do anything with an exhibit containing double standards but to disqualify it. I noticed that in some classes prizes were given after a disqualification, and was told that the reason was that all the competitors were equally culpable. Now, I hate this double-standard rule virulently, but I fail to see why one man should benefit by it while another loses. I agree with the views expressed by my brother, that judges, equally with exhibitors, are bound by the schedule. But, after all, the judges could only make a recommendation; it is the committee which accepted the recommendation which is at fault. I am at one with "A. B. Essex" as to this. I cannot say, however, that I am astonished. I have ceased to be surprised at anything done by the National Sweet Pea Society. I am utterly weary of its follies, and I have already sent in my resignation. The beautiful *coup d'aile* which we have always enjoyed so much at the show was ruined this year by the ugly backgrounds.—WALTER P. WRIGHT.

—In reference to this question, and without entering into the merits of double *versus* single Sweet Peas, I am in full accord with Mr. Wright and his contention in your issue of August 3, page 390, namely, that the rules of a society are *equally binding* on judges, exhibitors and the society that offers prizes, and cannot legally, and ought not in common fairness to the exhibitor, be altered until the prize in question has been won outright, whether it has to be competed for once or a dozen times! To admit that a judge, or a set of judges, may alter the rules of a society to suit an occasion that may arise at any show would be to cut into the bed-rock of sound judging, and cause confusion and vexation to all concerned. Where the rules of a society (clearly stated) have not been complied with, judges have no option but to disqualify, however disagreeable this may be. I think, however, they are quite within their right in recommending a special prize to the defaulting exhibit equivalent to the position it would have occupied otherwise, providing, of course, it was not disqualified for fraud. There is room for careful revision in most schedules, as well as for a clear statement of the power and limitations of a judge's duty, and nothing but good can come from an impartial discussion of this subject.—N. F. BARNES, *Eaton Gardens, Chester*.

Sweet-scented Musk Wanted.—Will you kindly tell me if it is possible to get plants of the old-fashioned strong-scented Musk with small yellow flowers? I remember that one small plant would scent the whole room or greenhouse. I have bought four plants this summer, three in Hants and one in Lincolnshire, all at different nursery gardens, but they have no scent to speak of. Has the strong-scented kind died out, and, if not, where is it to be obtained?—A REGULAR SUBSCRIBER. [The point raised by our correspondent is an interesting one. We have not seen a scented Musk plant for several years. At a recent meeting of the scientific committee of the Royal Horticultural Society this question was raised by Mr. A. W. Hill.—ED.]

Abutilons for Greenhouse Roof.—Not long ago a correspondence took place in THE GARDEN with regard to the different purposes for which Abutilons might be employed. Among the various uses was that of clothing the roof of a greenhouse, for which they are particularly well adapted. Any one in doubt upon the subject would do well to pay a visit to No. 4 Greenhouse at Kew, where a plant of the rich yellow-flowered variety, Golden Fleece, is covering an expanse of roof. The specimen is bearing a great profusion of its attractive blossoms, and not only has it been in this condition for a long time, but is likely to continue till the autumn. Not the least desirable feature when Abutilons are used as roof plants is that in the winter, when as much light as possible is an important consideration, the plants may be pruned back hard, to the great advantage of the different subjects underneath. On the other hand, in a genial temperature, Abutilons will, if required, bloom during the winter months.—H. P.

An Interesting Flowering Shrub.—While many of the members in this genus are either trees or climbers, *Casalpinia japonica* is remarkable in forming a handsome, though somewhat straggling, shrub some six feet in height. Except in the warmest parts of the country it must be regarded as tender, but given the protection of a wall with a southern aspect it seldom gets injured by frost. This species flowers freely every year at Kew, where plants have been grown in a recess outside the Temperate House for the past ten years. The pale yellow flowers, of which the uppermost petal is striped with red, are borne in terminal racemes on the young growths in June. The shoots, as well as the midrib of the large bipinnate leaves, are armed with stout spines. To flower this plant successfully very little pruning is required; it is, however, necessary to shorten back some of the longest shoots occasionally. *C. japonica* is a native of Japan. It was introduced into this country nearly thirty years ago by Messrs. James Veitch

and Sons, and first flowered in 1887 in their Coombe Wood nursery.—W. T.

THE ROSE GARDEN.

ROSES WITH BAD HABITS.

(Continued from page 400.)

Marquise de Sinety.—I fancy I can hear some readers saying, "Surely you are not finding a fault in this superb Rose!" but I must reluctantly confess that its open flowers are often very poor in colour and extremely shapeless. I know one could remove them before they attained to this condition, but, still, I wish it had a better finish.

Etoile de France, the parent of so many of our recent red Roses, including Leslie Holland, would be a superb variety if it did not have "fits of the blues." After a few tropical days the colour is glorious, but a succession of dull days will bring out the objectionable tint even in the half-open blooms.

Harry Kirk.—What a grand Rose this would be if we could always catch it right; but, somehow, from a hundred plants one could not cut a dozen good blooms at any one time, owing to so many in the large clusters paling to a very pale straw shade and being woefully thin and ill-shapen. Of course, one could disbud, but then this ought not to be necessary in a garden Rose. Then mildew! What a culprit it is in this respect.

William Shean.—Truly a wonderful Rose when fastened securely to a wire and well displayed upon an exhibition table; but how does it appear in the garden? I venture to say this Rose has disappointed quite a number of enthusiasts, who think more of their garden display than they do of the show-tent for unless the blooms are staked they present a sorry appearance. Personally, I see no more objection to staking Rose growths than doing the same with Carnations, but there seems an objection to it by the amateur grower.

Lady Ursula is another hang-the-head sort, a fault which considerably discounts its usefulness in the garden.

Lohengrin when seen at a show almost compels one to order it by reason of its size, fulness and shape, but it has a peculiar habit of changing colour to a sort of bluish pink, a shade it is impossible to admire.

Mrs. Aaron Ward.—Exquisitely beautiful when it comes its true Indian yellow colour; but far too frequently nearly white flowers will appear, which considerably spoil the effect when the Rose is massed.

Mrs. Stewart Clark is far too vigorous to be used with other Roses, and I fear it has spoilt many arrangements owing to this excessive luxuriance. It may not be a bad habit, but I think nurserymen are to blame in not describing its growth, for it is

often marked as being "Vig.," the same term being used for, say, Caroline Testout. Grow it as a big bush, as I saw it at its raisers' at Belmont; then it is all right.

Maman Cochet, where it produces one perfect bloom, yields a dozen split or malformed. Is this the fault of the Rose or the grower? I rather think the grower is often to blame, probably by growing it in soil much too strong and rich, or by faulty pruning. I once saw a grand plant upon a south wall, evidently very moderately pruned, and quite a number of the blooms were of good shape. It is very strange that the white sport comes more frequently good in form than its parent. P.

(To be continued.)

ROSE A PARFUM DE L'HAY.

IN spite of its cumbersome name, this is a very useful early-flowering Rose. It is a Hybrid Rugosa, but much nearer the Hybrid Perpetuals with its splendid foliage than Mrs. Anthony Waterer. It is brighter in its crimson colour; in fact, quite near the colour of General Jacqueminot. The flowers are large and double, rarely coming perfect, but when in bud are very pretty, and their fragrance is delicious, quite as unctuous as some of the best Hybrid Perpetuals. Mrs. Anthony Waterer has the unique habit of flowering the whole length of its growth, so that on standards the drooping shoots are quite of a crimson glow. The Rose under notice has not this peculiarity.

These Hybrid Rugosas are very fine things, and should be more frequently planted. If pruned down to about three feet or four feet, they make fine round bushes. This is better than leaving them unpruned, as some do, because then they become rather ungainly in appearance. If we could get a good crimson Conrad F. Meyer, it would be a great gain. This latter upon an east wall has been much admired this year, some of the blooms being quite of exhibition standard. E.

ROSE BLUSH RAMBLER.

HAD I to be content with one climbing Rose, I should unhesitatingly select Blush Rambler.

Year after year it comes regularly into bloom in June, and is literally smothered with flowers from base to summit. It requires no special treatment, simply needing to be well planted in full sun with a pole or pergola to climb up. Left to go its own way, there is no more pleasing sight in the Rose garden. It is perfectly hardy, and therefore needs no protection in winter. All that it asks for is that the old wood should be cut out after flowering, so as to allow the young shoots to ripen. Blush Rambler has the good quality of not having "bare legs" like so many climbing Roses, it being clothed with foliage, and frequently flowers down to the ground.

Weybridge.

THE GREENHOUSE.

MALMAISON CARNATIONS.

[In Reply to Several Correspondents.]

QUITE recently several of our readers have expressed a desire to know something about the general cultivation of these ever-popular flowers, and as the subject is of seasonable interest, we gladly accede to their wishes. In one instance the request is for information "from cuttings to flowering plants and to flowering them a second year." At the outset we may say at once that experience

is essentially a greenhouse subject, not one to be coddled to death in the close, stuffy atmospheric conditions of an ordinary greenhouse where artificial heat is applied or misapplied without rhyme or reason, but one to which overhead protection at all seasons of the year is an absolute necessity. Of equal importance, if any measure of success is to follow, is an airy structure where condensing moisture—that great creator of the dreaded rust—is a thing unknown. Light, therefore, and a free circulation of air are important factors in the case. Then it must not be overlooked that the Malmaison Carnation plant is nearly or quite hardy—we have, indeed, known the plants to endure for years in the open in both light and heavy soils—but for the reasons given above, and because the flowers are invariably ruined by wet, its cultivation in the open air is not seriously or generally undertaken. We make mention of the hardness of the plant, however, to demonstrate that, while requiring overhead protection, it is also quite opposed to artificial heat beyond that which maintains a dry, buoyant atmosphere. The need for artificial heat, then, is chiefly to dispel damp and to secure a temperature of about forty-five degrees or rather more. Hence, unless a house can be devoted to the plants, only such things as are likely to do under similar conditions should be associated with them.

Securing the Plants.—Established pot plants may be secured at almost any season of the year, while the young plants—the product of the current season's layers—are usually available from September onwards. The plants at that time are in 3-inch or 4-inch pots, and will be safe therein till the turn of the days, when a shift to 5-inch or 6-inch pots should be given. Occasionally the young plants are accommodated in a pit or frame, and these, if light and airy, answer quite well for a time.

Soil.—Rich pasture loam—that known as top spit and with a tendency to heaviness—is the best so far as the staple soil is concerned. It should have been stacked some months prior to use, and if manure was added at the time, no further manure will be necessary at potting-time. The addition of good leaf-mould, with a little soot and sand, will be all that is necessary, though bone-meal at the rate of a 5-inch potful to each bushel of soil is advantageously employed by some.

Potting.—In all the stages the potting must be firmly done. Loose soil about the roots would constitute a fatal error. The soil should be fairly rough, and where a sieve is used, that having an inch mesh will be found quite small enough. The pots should be perfectly clean and dry. New pots, by reason of their moisture-absorbing character, should be soaked in water for a short time, and subsequently allowed to become dry before being used. A free and ample drainage is very necessary.

ROSE BLUSH RAMBLER COVERING AN ARCH IN A WEYBRIDGE GARDEN.

has shown that by far the best results follow when the plants are propagated from layers, and that cuttings are only resorted to by experienced cultivators or propagators and for some specific purpose. In such circumstances, therefore, the cutting system is dismissed without more ado as being unsuitable to the amateur or beginner. The layered plant, on the other hand, and more particularly when established in a pot, is a good foundation, and with such, given attention to cultural details by the way, success may be secured with comparative ease.

Making a Start.—In the first place, we cannot too strongly emphasise the important fact that for all practical purposes the Malmaison Carnation

B.

At potting-time the ball of earth containing the roots should be on the dry side, the potting soil mixture being in a similar condition. Thus arranged, the soil can be firmed with impunity. Not so, however, should the soil be unduly moist, since the necessary ramming would render it adhesive, and therefore uncongenial as a rooting medium for the plants.

(To be continued.)

THE KITCHEN GARDEN.

THE FENNELS AND THEIR CULTIVATION.

THE common Fennel (*Foeniculum vulgare*) is a well-known plant in good gardens where a collection of herbs is grown for culinary purposes. It is a South European plant, and regarded as being indigenous to the coasts of Britain from Norfolk to North Wales. It is used for fish sauces and garnishing. It is a perennial, but a short-lived one under cultivation, especially if it is allowed to flower and seed; but this is not a serious drawback, as it is easily raised from seeds, which should be sown in lines 2 feet apart. Naturally, it enjoys a light, warm soil.

In addition to the above there are two other Fennels which are practically unknown in our kitchen gardens. They are, however, well worth cultivating in good establishments where variety is looked for; and many people who have enjoyed them in Italy are at a loss to know where to get seeds and how to cultivate the plants in this country.

Foeniculum officinale, or Long Sweet Fennel, is closely allied to the above, but is a much stouter plant, with less finely divided leaves. This plant is best grown as a biennial for use during spring, and should be sown during September, in lines 2 feet apart, on light, warm soil. It is generally used raw, the flower-stems being used while they are running up to flower. The *Carosella*, which is considered such a great

delicacy in Naples, is supposed by some authors to be a form of the above, or else closely related to it. The fresh, tender stems, still enclosed in the sheathing leaf-stalks, are broken in lengths and served up raw. The seeds of the above and the common Fennel are used in the manufacture of liqueurs.

Foeniculum dulce, Finocchio or Florence Fennel, is an annual and a native of Italy; it is the most important one for cultivation in this country. Compared with the above, it is a much shorter-growing plant, and very short-jointed at the base. The light green leaf-stalks are very broad at the base, and overlap one another so much at the base of the stem that they form an enlargement varying in size from that of a hen's egg to one's fist; this enlargement is white and sweet inside, and may be eaten raw, but is generally boiled, when it has a sweet, delicate flavour. Its cultivation is quite simple, as seed may be sown about the end of March in drills from 20 inches to 24 inches apart.

When large enough to handle, the seedlings should be thinned out, leaving them from 9 inches to 1 foot apart.

With the exception of plenty of water during dry weather, the plants require no other attention until the enlarged leaf-stalks are about the size of a hen's egg, when they should be half covered by drawing some soil up to them. In about a week or ten days the most forward may be cut for use. If required, successional sowings may be made throughout the summer. J. C.

THE ROCK AND WATER GARDEN.

A LOVELY WOODLAND ANEMONE.

(*A. APENNINA*.)

THIS is the wild Anemone of Italy, and takes the same place in that country as our own

effect. There are situations in most gardens where this Anemone could be planted and left to take care of itself, when, after a few seasons, lovely pictures, growing in beauty year by year, would result. In thin plantations or woods where the sun can reach it, charming effects may be obtained. It gives increasing proof of its value with each succeeding spring. In beds and borders its starry blue flowers, rising above the deeply-cut leafage, have a delightful effect; but it is when naturalised on grassy slopes or in woods of deciduous trees that it is seen at its best. It spreads its soft blue around the boles of giants of the woodland in yearly increasing breadths, here and there rising through a network of trailing Ivy and holding its own without apparent effort. The sight of a colony of these flowers, clothing a grassy knoll at the foot of a great Oak or Elm with a veil of blue, is a lovely picture on a morning in early spring, the colour-effect being enhanced if Lent Lilies in quantity are associated with them, the pale yellow of the

THE APENNINE WINDFLOWER (*ANEMONE APENNINA*), IN A ROCKY BANK. NOW IS THE TIME TO PLANT.

Wood Anemone does in our copses and woodlands. It is a charming little plant, with downy leaves, divided somewhat like those of *Anemone nemorosa*, and of a tender green hue. The blossoms are sky blue in colour in the interior and paler on the outside, with from ten to twelve star-like divisions, which are narrowly elongated and surround a cluster of whitish stamens. It blooms in April and flourishes in open woods, copses and shrubberies. It thrives best in a porous soil rich in humus. There is a pure white variety and one with dark violet flowers, as well as a double form; but none is as beautiful as the clear blue type. As it may now be procured in quantity at a very cheap rate, there is no reason why it should not be planted extensively in the autumn by all and sundry. To dot it about in small clumps in the beds is a poor way of growing it; but by planting it in the grass we can view it under conditions similar to those it luxuriates in on the Italian sward, and it creates a delightful

Narcissi forming, with the azure of the Anemones, the varied greens of the grass and of their respective foliage, a colour-harmony exquisite in its gradation of tints. Such glimpses as these, obtainable in almost every garden at a trifling cost, are far more satisfying to the eye than the infinitely more expensive and less natural breadths of gaudy bedding plants, to which, later in the season, the greater part of many a garden will be devoted.

A. apennina has been naturalised by the thousand in numbers of English woods, so much so that by some it is considered to be a native plant. Where it is happy and the soil is to its liking, it spreads rapidly, both by seed and by underground stolons, and soon occupies a large expanse of ground. In the rock garden it seems as much at home as when nestling at the foot of some monarch of the glade, and, blooming among the curtains of white Arabis, it is one of the prettiest features of the spring months. In the accompanying illustration it is shown growing at the foot of a steep rocky bank at

the end of a wood, where a few corms were planted many years ago. These have increased to such an extent that they now occupy the whole ground space at their disposal, and are a pretty sight when in flower in the spring, many of the blooms being pure white.

WYNDHAM FITZHERBERT.

CAMPANULA G. F. WILSON.

OF the many charming members of the Campanula family which delight us with their flowers from mid-June and onwards (just when the chief flush of the alpine garden is likely to be waning), that known as *G. F. Wilson* easily holds a prominent position. In stature it somewhat resembles *C. pulla*, but the foliage is more hairy, and it has much larger and wider, open flowers, while with me at least its constitution is much more vigorous.

The freedom with which it flowers is simply amazing, sheeting that portion of the garden which it inhabits with rich blue, and usually remaining in flower for six or eight weeks. This, naturally, depends on the weather conditions, however,

CAMPANULA G. F. WILSON, A DWARF PLANT FOR THE ROCK GARDEN.

since heavy rains will sometimes lay the growths on their side and otherwise damage them. In this respect, however, owing to its dwarfer habit (it rarely exceeds 3 inches in height), it is not so prone to destruction as its rather taller relative *C. pulloides*, which with me sometimes suffers rather badly.

I find that any tolerably sunny position in light, gritty soil with some humus added suits this decorative Bellflower admirably, while if it is desired to propagate it, every tiny piece of the cream-coloured underground stems which begin to "push" in myriads in the early part of the year (often about the end of March) will readily root if pulled off, potted up in light soil, and kept moist and shaded, very often flowering profusely the same season.

This plant looks particularly well if planted round the edge of a good-looking lump of stone in the alpine garden, both at its base and up the more or less vertical sides, so that when in flower the stone appears to emerge from a perfect garland of dainty bells.

REGINALD A. MALBY.

TREES AND SHRUBS.

THE BLUE-FLOWERED ABUTILON.

I AM sending you a photograph of the blue-flowered Abutilon, which we have here growing in the open, but sheltered to some extent, as it is in an angle of a wall, protected from north and east.

It was raised from seed and flowered well last summer, after which there were a number of button-like seed-vessels on it, but it did not produce good seeds. This year it has reached a height of nearly thirteen feet. It has been in flower for nearly two months, and was past its prime when the photograph was taken. It has set seed more sparingly this year, but they are round knobs and promise real seed. Any hints as to preserving the plant (I am told the plants always die after flowering profusely) or raising cuttings will be very welcome.

Dangstein, Petersfield.

(Mrs.) M. LANE.

A HANDSOME AMERICAN TREE.

DURING the early summer of the present year, a few abnormal flowers were produced by a specimen of *Cornus Nuttallii* growing in the Arboretum at Kew. Though not in their true character, they were developed sufficiently to show what an attractive plant a well-flowered example must be, while in the autumn the brilliant colour which gradually spreads over the leaves reveals another feature for which the species is famous. Writing of *C. Nuttallii* in the "Silva of North America," Vol. V., pages 70-71, Professor Sargent says: "The flower clusters are more beautiful and conspicuous than the flowers of any other tree of the Pacific States; and in early spring when the great flower scales have grown to their full size, it lights up the dark and sombre forests which are the home of this Dogwood as with a bridal wreath, and as with tongues of flame late in the year, when the beauty of the brilliantly coloured leaves and large heads of bright fruit is often heightened by the appearance of autumnal flowers."

In North America it is found as a moderate-sized tree 40 feet to 60 feet high, or, when growing under the best conditions, 100 feet in height, with a trunk up to 2 feet in diameter. Its ovate leaves are from 4 inches to 6 inches long, 2½ inches to 3 inches wide, and downy on the under surface. The small yellowish green flowers are borne in dense round heads, which are conspicuous by reason of the four large white bracts which surround each head. In autumn the buds for next year's flowers may be recognised at the points of the shoots. During September the leaves assume a bright red hue and are very conspicuous. In America it is said to luxuriate in moist but well-drained soil beneath the shade of coniferous forests at an elevation of 3,000 feet to 5,000 feet above sea-level. The wood of the trunk is stated to be hard, strong, close-grained, and suitable for cabinet-making and for turning into small articles.

W. D.

THE FLOWER GARDEN.

SWEET PEA NOTES.

Sutton Green and Hinckley.—I think everyone is now agreed that the duplication of the National Sweet Pea Society's trials was an excellent step on the part of the committee. Curious differences were observable in the same varieties at the two places, a stock being mixed at one and true at the other; but this does not detract from the undoubted practical value of the experiment, which ought to be maintained if within the bounds of possibility. The season has been such an extremely busy one that fewer people than usual were able to go with the two expeditions which started from London; but those who did were more than pleased with the manner in which both Mr. Foster and Major Hurst had carried out the many details in connection with their onerous task. They deserve universal thanks.

Honoured Varieties.—The year 1912 will be notable for the fact that there were scarcely any really outstanding novelties in the trials. I do not desire to suggest for one moment that there was nothing good, but simply that there was no variety which caused all the world and all the world's wife to send forth a song of delight and admiration. The floral committee noted this, and withheld the honour of reserving a variety for a silver medal next year, and did not even go as far as to give a first-class certificate. Does

[Unfortunately, it is only possible to cultivate this beautiful Chilean shrub, *Abutilon vitifolium*, successfully in the open ground in the milder parts of the country, but in Devonshire and Cornwall it is usual to find magnificent bushes 6 feet to 16 feet high and as far across. Although not a very long-lived shrub, it may be depended on to grow and blossom freely for a number of years, while it is readily replaced by growing young plants from seeds, which ripen freely. Cuttings inserted in pots of sandy soil in a close and slightly warm propagating-frame may also be rooted. When a bush is inclined to become loose in habit, it is a good plan to shorten the branches considerably in February. This will result in more branches and a greater flowering surface. The flowers of *A. vitifolium* are large and showy. On different plants they vary somewhat in colour, but are usually blue or violet, although white ones are known. The same bush may be expected to bloom freely for ten or twelve years, although bushes which have bloomed well sometimes collapse for no apparent reason.—ED.]

this mean that we have reached the supreme point in Sweet Pea development, or simply that raisers are lying low for a time with a view to startling us another season? I think that a negative answer must be returned to both of these questions. There is still room for improvement in our favourite annual, and it will come, though the advancement will be slower in the future than it has been in the past, while raisers who have distinct beauties are not likely to hold them back any longer than they are absolutely obliged, for fear that a rival should come along with something similar, but even better, and reap the golden harvest. We are always waiting and hoping for the pure blue and the pure yellow!

Beautiful Whites.—My friend Dr. Hinton of Heytesbury was good enough to send me a short time ago a few flowers of his new white Constance Hinton, which is a real beauty, and will undoubtedly enjoy a wide popularity when it is put upon the market. I dare not go as far as to affirm that it will turn out Etta Dyke, but it is the equal of that splendid variety in more than one respect. In the earliest stages of development there is a green marginal tinge, but this soon passes and there remains a pure white, large, but exquisitely refined blossom. Practically all the stems are fours, and the individual flowers are well set. Constance Hinton did well at both sets of trials, and was much admired. King White, from Messrs. A. Dickson and Sons, Limited, Newtownards, is full of promise, and will certainly be seen again. It was given an award of merit. Stark's Florence Wright Spencer was also excellent.

A Common Variety.—I wish it to be clearly understood that I do not use the word "common" in the deprecatory sense, but to indicate that the variety Decorator, which received an award of merit, came from several sources. It is most aptly named, for there cannot be many varieties which produce a more decorative effect in the row. The plant grows well, is extremely floriferous, and the rich cerise red colour makes it exceptionally conspicuous even in a big collection. Those sending it were Messrs. Dobbie and Co., Messrs. Stark and Son, and Mr. A. Malcolm of Duns, so it is fairly widespread already.

Other Novelties.—Mr. R. Bolton scored with two varieties. One of these is named Agricola, and it is of that peculiar mixture of rose and mauve that does not invariably do itself justice out of doors. It is a bold, handsome flower. The second was the monster lilac rose R. F. Felton. This is so very vigorous that, unless a tight hand is kept upon it, it will assuredly come on the coarse side. Bertrand Deal, named after its owner, rose mauve in hue, and Lady Miller, from Mr. A. Malcolm, palest cream, flushed

apricot, were the only others to receive awards of merit.

HORACE J. WRIGHT.

BULBS FOR AUTUMN PLANTING.

CERTAIN annual events always give me an unpleasant shock, in that they mark the too swift passage of Time. Birthdays are unwelcome milestones in life's journey, and Christmas, once

a death's-head at the feast of summer to remind us we must prepare for next season. It comes when the garden is ablaze with flowers and full of promise for another three months of luxuriance, when every space seems more than filled, and the chief work in hand is tying up those plants coming on and cutting down those going over, to give space and air in the crowded beds. Then suddenly "Bulbs for Autumn Planting" pulls one up on the curb, and dread visions of hitting those already in the ground and plans for the addition of others fill the good gardener's mind. Many there be, all the same, who are not good, and stifle their consciences with the thought that November is time enough to plant bulbs, and so put off the planning and ordering till then, and frequently December is near when those bulbs get planted.

I feel that I have a mission to such procrastinators and a message for beginners, and that I must proclaim aloud the wisdom of bracing the shocked nerves and grappling with the bulb question now that the catalogues have arrived. By ordering early you get the pick of the bulbs in the best condition for planting, and, also, many kinds, once in the ground, are rooting and improving in strength and vigour, even though they will not appear above ground for many months, whereas they would be losing weight and perhaps contracting diseases even in the best-regulated storehouse.

I am not inclined to sound the trumpet and call you to plant Daffodils, though they need early lifting and planting as much as any; for have not the readers of THE GARDEN a special High Priest of the Daffodil? Is it not our reverend friend's place, not mine, to preach upon that theme? To him, then, I leave the Daffodil and Tulip, his chosen mission field, while I plead for other, less popular plants, perhaps, but not to be omitted in any good garden.

What Shall we Plant?—How many ardent gardeners wail and lament to me every season that they cannot get Winter Aconites, Snowdrops, early Anemones and such plants to grow. Others are enraptured with, if not envious of, a neighbour's clumps of autumn Colchicums, Crocuses or Sternbergias. "I can't grow them." "My soil does not suit them." "All I plant are failures," so they wail; and to them I cry

aloud, "Read and mark, and order at once from your autumn lists."

Colechieums.—Remember these produce large, perhaps rather coarse, but handsome leaves in spring, so allow room for them and reckon on their deep, glossy effect among spring flowers in choosing their sites. Then go boldly ahead. The emperor of the family is the pure white *C. speciosum album*,

A GOOD SPECIMEN OF THE BLUE-FLOWERED ABUTILON
(*A. VITIFOLIUM*). (See page 414.)

eagerly looked forward to as a season of pleasant surprises and gifts arranged for us by our elders, now that we are older entails such efforts of organisation and shopping that the sudden realisation that the time has come to begin it all is always a shock to the nerves. A still worse shock for the nervous system is the arrival of the first list of "Bulbous Plants for Autumn Planting." It is

one of the loveliest of all bulbous plants, a White Swan Tulip in October. I remember when five guineas were asked—and given, too, by a few lucky possessors of such rarities—for single bulbs; but it is one of the consolations of advancing years to have lived long enough to buy this glorious treasure at the rate of 6s. a dozen. Messrs. Backhouse of York are the benefactors of the gardening world who raised it, and now distribute it at this low figure. The companionship of the rosy lilac typical form helps to show up the beauty of the white one, and if other good varieties can have space allowed them, Bornmülleri and giganteum are two that should not be omitted. The former has very large flowers, lilac, with a conspicuous white centre. The latter is much like speciosum, but has a greenish yellow tube that gives a pleasing finish to the large purple lilac blossoms.

E. AUGUSTUS BOWLES.

(To be continued.)

SOME NEW DAFFODILS.

[See Coloured Cover.]

With the exception of Bernardino, all the other Daffodils on the cover of this issue are specialities of

colouring round the cup is Lavender, which was raised by Mr. P. D. Williams, and which first saw showlight at Birmingham some few years since. Little Joan has not such a wide and pronounced edge, but it is a far more shapely flower, and one which would bring credit to the most select exhibit.

Just below it, on the right, is Bernardino, which is, as I always say, one of the *finest of all Daffodils*. I put it in the very front rank. Certain Daffodils we may call unitarians, some duotarians, others trinitarians, as far as they combine in themselves excellences for garden, exhibition and cutting. Bernardino is a trinitarian. Tall, robust, rapid increaser, floriferous and graceful is its character out of doors. On the show-table it has delicacy of colouring, good balance, shapely perianth and a general attractiveness which is catholic in its appeal, while when cut in a partly-expanded state, with a good long stem, and allowed to open in water so that all its beautiful apricot red tints are retained, it is certainly second to none in its loveliness. No one in the future will regret £2 spent on a bulb now. It will always be a great flower.

On the extreme right we have quite a different type, of which there are none too many—drooping

blooms *well* above the foliage, possibly a bit of the "rough-and-tumble" look about it. I have named it Mrs. Gamp. In the letter referred to, enough was said to whet my appetite; and a few bulbs of White Countess are coming this way to try conclusions next spring with my old lady.

It is increasingly difficult to keep pace with the red eyes. I have not seen Red Lady to know her. The fault may be mine and she has exposed her charms to unheeding eyes; or it may be that Mr. Bourne has picked it up out of Mr. Wilson's garden direct, or from his stand, where it would only be under number. The description is very taking, special emphasis being laid on the vivid red cup and the white over-lapping perianth. Mr. Bourne likes good new things. Judging from his excellent little illustrated price-list, he often falls a victim to their charms. It is full of novelties of all prices, from the rich orange-cupped Helios, which I almost think was the most striking flower of the 1912 season—price £15—down to White Countess and Selene, another giant Leedsii for the garden, which can be had, the one for 7s. 6d., and the other (Selene) for 5s.

Mr. Bourne won the gold medal of the Royal Horticultural Society for his collection of fifty at the Daffodil Show at Vincent Square this year. Considering the year, they were a very good lot, but I hear he is not satisfied altogether with his present ground. He has often told me that his wish is to put before his clients none but the best—the best varieties and the best-grown stuff. I know he will make every effort to do so. Hence it would not surprise me in the least to hear that he is seeking pastures *old* in a more favourable part of the British Isles for Daffodil culture than is the neighbourhood of Bletchley. For his own sake, and because he is the son of one whose memory every Daffodil-lover reveres, I wish him God-speed in his venture wherever he may finally settle down. JOSEPH JACON.

A RARE YELLOW PÆONY.

(PÆONIA LUTEA.)

This beautiful yellow Pæony is very little known, except to a comparatively small band of hardy plant enthusiasts. The late Mr. W. E. Gumbleton, one of the most discriminating of flower-lovers in his day, made a special study of the yellow Pæonies for some years, and three years ago we published a coloured plate of the yellow-flowered Pæonia Delavayi from flowers grown by him. *P. lutea*, of which we give an illustration, must certainly rank as one of the most beautiful of the yellow species. It was found in Yunnan in 1882 and sent to the Museum of Natural History in Paris, and has since been distributed. As it was introduced so far back, it is a matter for no little surprise that it should still remain scarce in cultivation. There are, however, one or two improved varieties in commerce, and the variety major, which surpasses the type in its intensity of colouring, is perhaps the best known. It is also worth recording that a fine double yellow-flowered Tree Pæony which bears the name of La Lorraine has recently been raised by the crossing of Pæonia lutea and a variety of *P. moutan*. *P. lutea* is a hardy species, requiring much the same treatment as the ordinary herbaceous and Tree Pæonies. It prefers a rich soil, and will thrive either under the shelter of a wall or in an open position. The flowering season is late May and June. For garden effect where choice plants are treasured, this gem is deserving of extended cultivation.

THE YELLOW-FLOWERED PÆONY (PÆONIA LUTEA).

Mr. Christopher Bourne. This gentleman, as readers of THE GARDEN know, has embarked in the Daffodil and bulb business, and it is his intention to become known as an introducer of refined flowers. Little Joan, figured in the plate, may be taken as a typical example of the type at which he is aiming. I admired it very much when I saw it on one occasion last spring. As may be judged from its proportions with regard to the others, it is on the small side (diameter of perianth $2\frac{1}{2}$ inches, cup three-quarters of an inch), and I fear would-be buyers will think very little is offered them for their money. But one must be prepared to pay if we want to acquire a novelty, and the delicate pink edge to the pale primrose centre is something which is at present very uncommon. The best-known flower with this pink tone of

or pendulous blooms, with a fairly long cup of red, and with white reflexing perianths. As Mr. Bourne says in his catalogue, they are Fuchsia-like in appearance. In old days we would have called Tritoma a Nelsoni. It has much of the character associated with this now-digested section, and, like them, it is a late bloomer. White Countess belongs to the giant Leedsii; I do not remember having seen it, but from what Mr. Bourne tells me, in a private letter written before I knew anything of this plate, it must be a nice thing. The cup never gets white and the perianth keeps flat. It came from Mr. Wilson, and it is described as a tall, fine garden plant. I know some of this good man's garden Leedsii. One, of which I bought the stock two years ago, is, in my opinion, the best I have ever seen in a garden—massive,

GARDENING FOR BEGINNERS.

HOW TO TAKE AND ROOT CUTTINGS OF BEDDING PELARGONIUMS.

At this season one's thoughts naturally turn to the increase of the different bedding plants for

1.—BEDDING PELARGONIUM SHOOT SUITABLE FOR MAKING INTO A CUTTING.

next year's display. Despite the fact that Pelargoniums are sometimes condemned, they still hold their own as one of the most popular of all subjects for the purpose, and our gardens would certainly be very much the poorer without them. Now is just the time to increase them by means of cuttings, which should be taken with as little delay as possible. In taking cuttings from the flower-beds, an important matter is to take those that will be less missed; that is to say, the bed should, when finished, show but few traces of having been interfered with in any way. At the same time, it may be pointed out that by far the best cuttings are formed of shoots of moderate vigour, as the very succulent ones are more apt to decay, a remark that applies equally to the weak ones that are overshadowed by the upper part of the plant.

Making the Cuttings.—A good length for the cutting is about four inches, and it should be prepared for insertion by making a clean cut with a sharp knife immediately below a joint and removing one or two leaves at the base. When a shoot is closely examined, it will be seen that each leaf has a wing-like scale at the base, which it is necessary to remove, otherwise moisture is apt to collect there and thus prove a seat of decay. In the case of most plants, it is very essential that the cuttings be inserted as soon as possible after being removed from the parent plant; but Pelargoniums form a decided exception to this rule, as they are, especially if rather succulent, all the better if laid out thinly on a bench for twenty-four hours before they are prepared for insertion. One effect of this is that the leaf-scales flag somewhat, and they can then be stripped off without difficulty, whereas when quite fresh the bark may possibly be torn a little in carrying out the operation.

Inserting the Cuttings.—The cuttings being all prepared, it must then be decided whether they are to be put in pots or boxes. This is, as a rule, determined by the question of the space available during the winter, as a greater number can be kept in boxes than in pots. If in pots, a good plan is to put four cuttings around the edge of a pot 5 inches in diameter, as may be seen in the illustration below. Whether boxes or pots are employed, it is most essential that they should be quite clean and effectually drained by placing a few broken crocks or oyster-shells over the bottom, disposing them concave side downwards. The boxes, of course, must have holes bored in the bottom, in order to allow the surplus water to pass away. A suitable compost for the cuttings may be made up of one part each of loam and leaf-mould, with half a part of silver sand, the whole being thoroughly incorporated together, and it will be all the better if passed through a sieve with a half-inch mesh, placing the rough portions which do not go through immediately over the crocks in the pots or boxes. In inserting the cuttings, the dibbler used should not be too pointed, otherwise a space will be left at the bottom of the hole when the cutting is put in its place, and this retards the action of rooting, for it is very essential that the compost is closed around the base of the cutting. Overcrowding, too, must be guarded against, while, on the other hand, it will be necessary to economise space as much as possible. By some a layer of clean sand is placed over the surface of the soil before the cuttings are put in (this was at one time universally done), but it has one great drawback, namely, it is difficult to ascertain the state of moisture underneath. For this reason it is by many discontinued.

After-Treatment.—The boxes or pots being thus filled with cuttings, they may be watered through a fine rose and stood in a sunny spot out of doors. If there is a frame available, so that they can be stood therein and the lights put on in the event of very heavy and continuous rain, so much the better. Still, it is not often needed at this time of the year. So treated, they will not take long to root, when, if there is plenty of space available

for the winter, they may be potted off singly; but where the question of room at that season is,

2.—THE CUTTING PREPARED FOR PLANTING.

as in most cases, a consideration, they may be left in the pots or boxes till the spring. During the winter, whether potted singly or not, they should be given a good light position in a structure safe from frost. The soil must be kept fairly dry, though not parched up, and the plants be frequently examined in order to remove any signs of decay. A shelf in the greenhouse is a very suitable place for these young Pelargoniums during the winter. H. P.

BLACK CURRANTS AFTER FRUITING.

I HAVE seen amateurs cut off the tops of the branches directly the fruit has been gathered, with the result that young shoots grew and formed tufts at the end of each one, effectually excluding the light from the centre of the bush. This bad practice unduly excited growth of a useless nature at a time when the wood and leaves should be maturing. Very old branches must be cut out now to admit light and air to the younger ones; then the latter will bear more and finer fruits next year. B.

GREENING SEED POTATOES.

MANY readers of THE GARDEN will now be selecting some of the Potato tubers for seed purposes next year. Indeed, all seed tubers should be picked out soon after the crop is lifted, and stored by themselves in cool, dry, well-ventilated buildings where plenty of light can reach them, but be safe from frosts. Before storing them in such places, however, the tubers, which should weigh from 2½ oz. to 3 oz. each, should be spread out thinly and exposed to the sunshine and light generally, under frame-lights or in an open shed. When thoroughly greened they will keep well through the winter. SHAMROCK.

3.—FOUR CUTTINGS PLANTED AROUND THE SIDE OF A 5-INCH POT.

GARDENING OF THE WEEK.

FOR SOUTHERN GARDENS.

The Flower Garden.

Lilium candidum.—The common white or Madonna Lily oftentimes thrives much more luxuriantly in cottage than in any other gardens, and does not seem so prone to disease. Recently I noticed a very fine effect caused by intermingling this subject with the scarlet *Lychnis chalcidonica*. The planting should not be deferred any later than possible. Have the ground well dug, selecting a piece of ground fairly porous and in good condition; while if the ground is heavy, add some light material, such as leaf-mould and road scrapings. Plant 5 inches or 6 inches deep, sprinkling a little powdered charcoal round each bulb.

Verbenas.—When grown in conjunction with other plants or separately on a sunny border, these plants make a striking display and are very effective, particularly for ribbon borders. The growths require to be periodically pegged down. Now is a good time to take cuttings for next season's display. Young growths taken off will soon root if dibbled fairly thickly into 5-inch pots containing a mixture (passed through a fine sieve) of loam, leaf-mould and plenty of sand. Make firm and stand in a cold frame, give a good watering in, keep close, and shade from bright sunshine.

Phlox decussata.—The varieties of these have been particularly fine this season and created a fine display, due, no doubt, to the occasional showers throughout the season, drought, especially on light soils, being fatal to their well-doing. Propagation may now be carried out and the cuttings treated the same as Verbenas, or dibbled into a shallow frame and kept close.

The Rock Garden.

Sedum kamtschaticum.—This is a fine plant for the rock garden and for planting beside paved walks at this season of the year. The growth is vigorous and the flowers are produced with wonderful freedom. Commonly known as the Orange Stonecrop, the orange yellow flowers are very conspicuous against the large green foliage. *S. glaucum* has also been an attractive plant and smothered with flowers.

Tunica Saxifraga flore alba pleno.—This is unquestionably one of the finest plants of recent introduction for the rock garden, and will become deservedly popular, particularly for its free and continuous flowering from early until late in the summer. The flowers are pure white, double, and graceful in habit, and the plant seems perfectly free in a dry season such as the last, but is also well able to withstand heavy rains.

Micromeria Douglasii.—For trailing over rocks or a wall, this North American plant is well adapted, being remarkably free in growth and of a trailing habit. The flowers, though rather inconspicuous, are, nevertheless, sweetly scented and of a whitish colour.

The Shrubberies.

Ceanothus azureus.—For flowering during this month there are several excellent varieties of this shrub, and two with which I am well acquainted and highly meritorious are Indigo (a variety with deep indigo flowers) and Perle Rose (a variety with large trusses of rose-coloured flowers). Another shrub of great merit is *Perowskia atriplicifolia*, the spikes of blue flowers contrasting well with the silvery tomentose foliage.

Plants Under Glass.

Early-flowering Bulbs.—The catalogues are now coming in freely, and I would advise the early ordering of those bulbs at least that are wanted to flower soon after Christmas or before, such as Roman Hyacinths, Narcissi and Tulips, and upon their arrival unpack them and store in a cool, dry position until potting or boxing is done. Almost any old potting soil may be utilised, but for preference a mixture of loam, leaf-mould, spent Mushroom-bed manure and coarse sand.

Chrysanthemums.—Those growing for big blooms will now need liberal feeding to build up the buds that are retained, varying the stimulants as much as possible. With artificial manures I think the better plan is to mix them in the water before applying. This is best done by gradually moistening and mixing in a pail of water, then stirring the contents into the bulk to be used.

Through constant waterings the surface-soil becomes sour, and when removing weeds lightly aerate the surface. If there is room, apply a little rich top-dressing. Keep the growths tied up as becomes necessary and remove superfluous shoots.

The Kitchen Garden.

Cauliflowers.—Between this date and the end of the month, according to the locality, is the best time to sow for plants to stand the winter, though in the South-West the first week in next month may not be too late. Select a suitable seed-bed, as previously advised, make a fine tilth and sow evenly but not too thickly, keeping the surface moist in the event of dry weather.

Cucumbers.—Make a sowing now for supplying fruits during late autumn and winter. Raise the seed, as previously advised, by sowing singly in small pots, and plunge the pots in a warm house. When germinated, elevate near to the glass. For this crop it is well to plant in a house that can, when necessary, be supplied with plenty of fire-heat, and also admit the maximum amount of light, otherwise the growth will be weak and fruitless.

Autumn-sown Onions.—For spring and early summer use the autumn-sown or Tripoli Onions are particularly useful, and I would certainly recommend a small bed being sown in any garden. If seeds are sown too early, the plants are liable to run to seed, but about the 20th of this month is a good date. Have the ground well worked, add plenty of soot and wood-ashes to the surface, and rake down finely before drawing the drills. White Leviathan, White Emperor and Giant Red Rocca are all good varieties, the latter keeping well.

Fruits Under Glass.

Strawberries for next season's forcing should by now be getting well established in their pots in which they will fruit. Keep the plants free from weeds and the runners picked off, but only in the case of leaves that are absolutely dead remove the foliage. Keep the plants well watered and damped over in the evening on warm days, and see that the pots stand quite clear of one another, so that the crowns may become well ripened.

E. BECKETT, V.M.H.

Aldenham House Gardens, Elstree, Herts.

FOR NORTHERN GARDENS.

The Flower Garden.

Sweet Peas.—These have made extraordinary growth, and it will be worth consideration whether or no to relieve the plants, at least of the top-most shoots, which otherwise will collapse and to a great extent spoil the effect for garden decoration.

Hollyhocks.—So far, the rust disease has been less troublesome than in some years, but it usually makes much progress once cooler nights arrive. The affected leaves should be removed every few days. See that the flower-stems are well secured, and the tips may be pinched out of the tallest, which will be effective in making the lower blooms finer. If seed for another year's stock has not been sown, it may still be done. If sown later the plants are very late in flowering.

Carnations are now in full bloom, and will from time to time need attention to remove the decayed flowers. Continuous-flowering varieties, such as the old Raby Castle and Duchess of Fife, will also need attention to see that the supporting sticks do not give way, and to tie the later stems loosely in before they fall over. Early layers will be well enough rooted to transplant. Nothing is gained by leaving them, because the roots spread a good deal, and a less well-rooted plant results if left too long. Belated shoots may yet be layered, but usually these must be wintered in pots, being too late in rooting for autumn planting, for which early-layered plants alone should be used.

The Wild Garden.

Bocconias.—There is no better time than the present for curbing the habit for over-extension displayed by these. The parts to be removed are first severed from the mass to be kept by means of a sharp spade, and the underground shoots, being first eased with a fork, are not difficult to draw out of the ground. The tall Eastern Polygonums are even more inclined to overrun bounds, and they may be treated in the same manner. Cutting down the stems only delays for the moment

what must be done later, when the operation can be less easily and perfectly executed.

Campanulas.—The seeded shoots of *C. latifolia* and any others of an allied habit should be removed forthwith, not only on account of appearance, but because the seeds germinate so freely as to become a nuisance. Caution must also be exercised with the Umbelliferae. *Heracleum*, for example, if left to seed, is almost impossible to keep under, dressing the superfluous plants with sulphuric acid, which must be applied singly, being perhaps as satisfactory a way as any. Foxgloves, as a rule, may be left to themselves, also *Honesty*. Any time from now strong seedlings of various plants may be introduced.

The Vegetable Garden.

Mushrooms.—Where material for forming Mushroom-beds is to be had, a commencement may now be made for a bed to come into bearing in October. The chief care is to see that the material is not overheated, which not only produces inferior Mushrooms, but considerably shortens the time of bearing.

Cucumbers.—Though early plants are still bearing, it is desirable to provide for autumn and early winter by sowing enough seeds to produce plants for a fresh stock. The plants in crop will now ask for some artificial heat day and night to induce the continued production of new growth. Water at the root will possibly need to be curtailed, and overcropping should be strictly discontinued.

Tomatoes.—Provision for an early crop next year must now be made. This may either be done by sowing seeds or by cuttings, which root quite freely, provided they are not killed with too much moisture. The drawback to cuttings consists in the stems getting too hard, which is prevented by careful treatment throughout, and these have the advantage in ripening fruit earlier than seedlings.

Parsley.—Some of the old plants may be cut over to make young growths to come on for spring picking, and the seedlings from a late sowing be thinned to 4 inches or 6 inches apart. Thereafter the ground should be nicely hoed and cleaned. The main crop, if given plenty of space, will now be quite handsome, and will provide splendid material up to Christmas at least.

The Plant-Houses.

Gloxinias.—Those grown coolly will now be in flower, and with seedlings of the present year will be very useful for the conservatory and house decoration. They require rather careful watering, otherwise the foliage and the flower-stems damp. Early-flowered plants may be dried off and placed for the winter under the stove stages.

Cyclamen.—These are now making their last crop of leaves, and those in rather small pots and thoroughly well rooted will be all the better for occasional dressings of manure. Shading, except on very hot days, should be dispensed with. Old plants may be shaken out, repotted and placed in cold frames, kept close, where they will shortly begin to grow. Water must be very sparingly and carefully dispensed until growth recommences.

Chrysanthemums.—Bush plants, if growing rapidly, should be rather under-watered for two or three weeks to harden growth and keep them from growing too tall. Meanwhile, aphid will, in all probability, attack the young expanding leaves, a pinch of Tobacco powder affording a certain preventive.

Hydrangeas.—Young plants intended to be forced early next year should have only a limited supply of water at the root, in order to harden the wood and induce the formation of flower-buds, gradually lessening the supply and keeping the plants quite cool. The foliage also will mature and decay before winter, when the plants will go to rest.

Humeas.—These must on no account be permitted to get dry at the root, which is fatal, and if the pots are stood on a cool, moist bottom it is beneficial to the plants.

The Fruit-Houses.

Peaches.—For the next few weeks these will ripen very fast, and it is of advantage, if it is essential to delay ripening, to shade the trees heavily with mats, which may either be placed in front of the trees trained to back walls or be spread over the glass. The object is to keep the temperature low; consequently it is imperative that something thick, such as mats, be employed.

R. P. BROTHERSTON.

Tynninghame, Prestonkirk, N.B.

ANSWERS TO CORRESPONDENTS.

RULES FOR CORRESPONDENTS.

QUESTIONS AND ANSWERS.—The Editor intends to make THE GARDEN helpful to all readers who desire assistance, no matter what the branch of gardening may be, and with that object will make a special feature of the "Answers to Correspondents" columns. All communications should be clearly and concisely written on one side of the paper only, and addressed to the EDITOR OF THE GARDEN, 20, Tavistock Street, Covent Garden, London, W.C. The name and address of the sender are required in addition to any designation he may desire to be used in the paper. When more than one query is sent, each should be on a separate piece of paper. Plants for naming should be clearly numbered and securely packed in damp grass or moss, not cotton-wool, and flowering shoots, where possible, should be sent. It is useless to send small scraps that are not characteristic of the plant. Letters on business should be sent to the PUBLISHER.

FLOWER GARDEN.

WATER LILY (A. L.).—You had better isolate the affected plant, first laying it on a bag or mat and syringing it with an emulsion of soft soap and paraffin, 4oz. of the former and a wineglassful of the latter to two gallons of rain-water. Should the pest occur on the other plants, you should obtain some Tobacco rag and place it in a sack in the tank. By moving the sack from time to time the water will become charged with the juices from the Tobacco, and in time clear off the pest. If only the one plant remains affected, the cheapest way would be to discard it by burning.

LILY DISEASE (J. H. W. T.).—We know of no cure of the disease once it gains a footing. It may be kept at bay, or at least prevented from doing material damage, by an early spraying with sulphide of potassium, say, half an ounce to a gallon of soft water. This should not be applied oftener than once in three weeks, and it is important that a light spray syringe, such as the "Abol," be employed to ensure the wetting of both the upper and under surfaces of the leaves. This should be started in May and kept up at intervals till the flower-buds are fully grown. All you can do at the present time is to collect and burn all diseased leaves and stems, and spray the plants once or twice during the season. Anything that is done—lifting and drying off and plunging the bulbs in a bag of sulphur have all been recommended—should be of a preventive order, as the spread of the disease is too rapid once it has taken hold of the plants.

SOWING ANTIRRHINUMS IN THE OPEN (Constant Reader).—You ask whether you may take the recommendation to sow these in the open—recently made in THE GARDEN at page 353—"seriously," and whether you "may depend upon plants so raised for your summer bedding?" Certainly you may! We have not only implicit faith in our contributor in such matters, but of our own knowledge know that the results stated are easy of accomplishment. The Snapdragon is virtually a hardy perennial, and July-sown seeds should, for your district at least, ensure seedlings large enough for going into their permanent quarters in October, or not later than mid-March if you decide to leave them in the seed-bed through the winter. Only in the event of a very severe winter and with late-sown seeds would the seedlings be likely to suffer in the open; hence the need for securing hardily-grown plants as opposed to such as are weak from an overworked seed-bed. This latter is the precursor of many ills, and is continued, despite frequent warnings to the contrary. You have failed in the past to get an early flowering by sowing seeds in "spring"—a rather indefinite term—and by reason of your late planting; and seeds sown now would give you no better results if you cannot plant the seedlings till the spring bedding plants are cleared. In such circumstances the case could only be met by potting the seedlings into 5-inch or 6-inch pots, so that their progress be not delayed and the check caused by transplanting be reduced to a minimum. An article on the Malmaison Carnation appears in this issue.

TREES AND SHRUBS.

QUICK-GROWING BUSHES AND TREES (J. F.).—Unfortunately, you say nothing about the size of the garden, and we are unable to give you any sound advice in the circumstances. If you will tell us this and give us also an idea of its position and surroundings, we will give you the names of suitable things. Please say also whether the house is to border the roadway, and, if so, at what distance from it. There are many things which might be planted in the months named. We hope, however, you will proceed cautiously, as the curse of many a garden eventually is the undue haste and density of early planting. The quickest-growing things, those you appear to have in the mind's eye, are not infrequently the most voracious and unbeautiful, and, while robbing the garden soil, prevent the introduction of more ornamental subjects. In any case it would not be wise to plant before the house is built, unless at the boundaries where no interference was likely.

THE GREENHOUSE.

CYCLAMEN AND GRUBS (C.).—The grub on the roots of the Cyclamen is that of the Raspberry weevil. It is likely to be found also feeding on roots of a succulent nature in other pots. The best way is to turn out the pots and pick out the grubs, but possibly you might be able to get rid of them by pouring into the soil (not touching the root) of each pot a few drops of carbon bisulphide. This is a very poisonous compound, very evil-smelling, inflammable and explosive, and must be used with the greatest care. The grub becomes a beetle, which feeds on foliage at night, and may be caught by spreading a sheet of paper beneath plants attacked and shaking them or shining a sudden light upon them.

FRUIT GARDEN.

INJURY TO APPLES (The Rosery).—The Apple trees have been badly attacked by the Apple leaf-curling aphides. It is too late now to do anything. The trees should next year, at the end of February or beginning of March, be sprayed with alkali wash, and if this does not suffice, as soon as aphids appears in the spring spray with a nicotine wash or with quassia and soft soap.

MELON FOLIAGE DISEASED (H. G. N.).—Judging from the appearance of the leaves, we think the plants have been growing recently in too moist an atmosphere. They have also the appearance of having made a too gross and soft growth by having too much soil to grow in. This condition nearly always brings disaster to the Melon at the later stages of its growth in causing the foliage to damp off, as in your case, or in canker. The Melon does not require very much soil to grow in; it likes a heavy loam, pressed as hard as possible, and in its later stages of growth should have free ventilation in fine weather, not too much water at the roots, and a dry, warm air.

STRAWBERRY PLANTS NOT FRUITING (M. G. K.).—Your experience with Strawberries has been unfortunate. We think the hot, dry season of last year is primarily responsible for the failure. The crown of the plants in consequence of the drought failed to develop a free growth of crown buds (flowering buds), hence the failure. We would give them another chance, as there is no reason why they should not flower next year if the runners in the first instance were taken from fruiting plants. Try another plan with a few new runners as follows, and you will have a heavy crop next year. Trench your ground 2 feet deep, add well-decayed manure freely (say, a bushel to a square yard), mix well with the soil and plant in rows 18 inches apart, the plants in the row being 15 inches apart. Instead of planting one plant in the row at this distance, plant three a few inches apart only, treating the three as one plant. Procure strong, well-rooted runners as early as possible, and plant out not later than the middle of July.

PEACH LEAVES (J. L.).—The Peach leaves are attacked by the Peach shot-hole fungus (*Cercospora circumscissa*). The fungus frequently fruits on the pieces of leaf that drop out, so that all fallen leaves should be picked up, and, when spraying is done, the ground below the trees should be sprayed as well as the trees themselves. We think, for spraying Peaches, you would find commercial copper carbonate better than potassium sulphide. It is made by making 5oz. of copper carbonate into a thin paste with water, adding three pints of the strongest ammonia (880), which should produce a clear blue solution, and diluting with forty-five gallons of water. The spray must be applied like a mist, and it is possible it may have to be repeated.

FIG TREE CASTING ITS FRUIT (Ficus Investilis).—Figs in gardens have frequently been planted in a haphazard way, with young trees raised from pips or seed. When this is the case, satisfactory crops seldom or ever follow. The best sort to plant out of doors is the Brown Turkey. There are many causes responsible for the Fig tree casting its fruit. The following three are the most common: (1) The overcrowding of the branches in the previous summer at the time when the tree was in full growth. It is a well-known fact in the successful culture not only of the Fig, but of all hardy fruit, that the first essential is that the shoots of the previous year's growth (these are the shoots which produce the fruit) should be well developed, and as perfectly matured as possible, by the end of the summer. Unless these shoots have been well exposed to all the light, air and heat possible during their season of growth, these conditions cannot be secured. See to it that the best shoots on your tree this year are not choked with weak and useless branches, shutting out light and air. Do not hesitate to cut out to their base such worse than useless shoots. (2) Dryness at the roots. Both the wood and foliage of the Fig are of rather a soft and pithy nature, and, therefore, to keep in good health, should not be allowed to suffer from want of water during their season of growth. Trees growing against walls are liable to suffer from drought. Water quickly percolates away into the foundations. Moreover, trees are sheltered from rain by the walls. For instance, a driving rain from the north is little or no use to a tree planted against the south side of a wall, and the same in respect to other aspects. Therefore good growers never fail to give their trees a good deluge of water during the summer, and even in autumn and winter, too, occasionally, using weak liquid manure at each watering. (3) Injury from frost. It frequently happens that the young embryo fruit is damaged by frost. The damage may not be apparent at the time, and the young fruit may grow afterwards to a certain size before this is found out; but the flowers fail to be properly

fertilised, and as a consequence fall. A good way to prevent damage by frost is to have some portable straw hurdles made to fit closely over the tree, which can be placed in position during hard frost in winter, and removed in open weather and replaced again if wanted. The stem and lower branches of the tree should be bedded down with straw or fresh leaves to the depth of 1 foot. This will protect the stem and roots as well. We have had trees covered up for a month or longer in hard frost, and no harm has resulted.

KITCHEN GARDEN.

TOMATO LEAF (W. J.).—The Tomato leaf shows round, greenish blotches, and has the appearance of having been in an over-moist atmosphere, or of having been fumigated while wet.

TOMATO (A. S.).—The Tomato is attacked by the Tomato black-spot disease. All such fruits should be picked off and burned, lest they spread the fungus *Macrosporium solani*, which is its cause. The plants should have attention to watering so that they do not become dry at any time, and now and then a little sulphate of potash should be given, for that tends to harden the skin and prevent cracking.

CUCUMBERS (C. L. de T.).—The temperature has evidently been allowed to fall too low for the Cucumbers, and they have also apparently been growing in sour soil. No fumigation or spraying can counteract these troubles. The little insects could be killed by fumigation with XI. All, but dusting with flowers of sulphur would be safer in the Cucumber-house. The fruits are gumming badly, and evidently suffering from bad conditions of growth.

CAULIFLOWERS (F. C. T.).—The Cauliflower has been attacked by the Cabbage-root maggot, a pest which is very prevalent this season, particularly in light soils apparently. In some places the whole of the Cabbage crop has been ruined by it. The grub is hatched from small white eggs, very like those of the blow-fly, deposited by a fly very similar to the house-fly on the roots of the Cabbages and other plants nearly related to them, in May onwards, two or three broods being produced in the course of the year. The grubs feed on the young roots and subsequently burrow into the stem. The pest is very difficult to deal with; but possibly the best means is to sow along the rows sand moistened with paraffin. This must, of course, be renewed at intervals, for the fly attacks the plants at all stages of growth.

MANURING TOMATOES (Anxious).—Do not be too hasty in giving your Tomato plants liquid manure. It is very probable that the pots are not full of roots, or the plants have not begun fully to fruit. Too much haste in using liquid manure is apt to generate coarseness, and often disease. To make liquid manure, put eighteen gallons of water into a large tub, then into that a bag containing 50lb. of pure horse-manure; let the bag be coarse and loosely tied. This should soak for forty-eight hours before being used; or you may obtain half a bushel of poultry-manure or of pigeon-manure, with which is added, in a bag, half a bushel of soot, and soak for the same time. Failing either of these, obtain 6lb. of bone-flour, 4lb. of kainit and 2lb. of sulphate of ammonia; mix these and put into a bag. At first it should not be given to each plant more than once a week. A fortnight later give twice the quantity. At the first watering a pint to each plant is ample.

MISCELLANEOUS.

HONEY DEW (C. S. D.).—The black deposit on the Currant leaves is a fungus growing on honey dew. The honey dew is the product of the aphides which have been feeding upon the Currant leaves. The Currant should be sprayed with Quassia and soft soap as soon as the aphides appear. There will then be none of this unpleasant material upon the plants.

EDUCATION IN FRENCH (Enquirer).—Your desire to gain experience of methods of gardening in France and to acquire a knowledge of the French language is laudable. If you write to the secretary of the French Horticultural Society of London, G. Schneider, Esq., 17, Ifield Road, West Brompton, London, S.W., we have no doubt he will help you in the matter.

HOT-WATER PIPES (W. R. H.).—Although it is against all the theories of hot-water fitting to bury the hot-water pipes in soil, we do not see any other remedy for a situation such as yours. If the trench was filled up with soil to a little distance beyond the wall of the fruit-room, and a small space arranged in the flagstones at either end to allow the escape of any accumulated heat, we think the amount which would penetrate through the 3 feet or thereabouts of soil would be so infinitesimal as to do no harm.

JAPANESE TOY GARDEN (F. T.).—In some parts of your country much use is made of the hardy Heaths, and they are very beautiful and free flowering when rightly used. Of such plants you may select at will, since all are good for the purpose. Of small-growing shrubs you cannot do better than select *Abies pectinata* nana, *A. subalpina* compacta, *Pinus Cembra* pumila, *P. Laricina* pygmaea, *Retinospora obtusa* nana, *Cassinia fulvida*, *Veronica* cypripedifolia, *V. Hectorii*, *V. gutierreziana*, *V. pineloides*, *V. carnifolia*, *V. buxifolia*, *V. decumbens* and *V. anomala*, all of which are beautiful. *Yucca filamentosa* and *Y. angustifolia* are both good, and *Genista tinctoria* fl. pl. should not be omitted. Just what you might employ advantageously would depend on the size of the garden and the space at disposal, though for a sun-kissed spot you could hardly err in any section of *Eucalyptus*

Saxifrage, Dianthus Erodium, Campanula muralis, C. zarganica, C. g. alba, any of the silver-leaved Achilleas, Rocky Mountain Columbines, Polygonum vacinifolium and Zauschneria californica would afford variety and variety till quite late in the season.

NAME OF FRUIT.—S. J.—Gooseberry Gunner.

NAMES OF PLANTS.—F. J. Keop.—Buddleia variabilis veitchiana.—D. D. D.—1. Charles Lawson; 2. Amadis; 3. Rosa pomifera; 4. Tuscan; 5. Félicité Perpétue.—W. B. A.—Ulmus glabra—Rhavatt.—Rose Tuscan; the other plant is Veratrum or Black Hellebore.

BOOKS.

A Year's Gardening.*—The title is very suggestive of the book, which in large degree is a calendar of a year's work in the garden and greenhouse, taking the days as they come, and giving hints as to requisite or desirable work in "Greenhouse and Frames," "Vegetable and Fruit Garden" and "Flower Garden." Of necessity, the information imparted is of true calendar brevity, and not always of the best type. For example, on July 1 it is suggested under the vegetables and fruits that the "month be started by collecting together all garden rubbish which may have accumulated." Surely in midsummer there is more important work to be done than this! And should not this department at that time be cropped to its utmost? Parallel advice continues on following days, and if important in its day or right place, is surely unimportant now, when every inch of ground should be occupied. In the main, however, the hints given are good and seasonable, and the gardener, whether amateur or professional, will find the calendar portion useful and convenient for reference. Following the calendar part, a few pages are devoted to alpine, rock and wall gardens, and here the author, while still very brief considering the importance of the subject, gives himself a little more rein, pointing out the wrong and suggesting the right. "Lawns: Their Making, Maintaining and Renovation," "Fruit Trees: Training, Planting and Pruning," "Fruit Destroyers and Garden Pests" and "The Vegetable Garden Month by Month" are some of the features of which the book treats in more or less detail, sufficient, indeed, generally to constitute a guide—a finger-post, as it were, by the way. The book, which contains upwards of forty illustrations, concludes with an alphabetical list of flowering subjects, hardy, tender, bulbous and the like, together with brief cultural hints. So far as we have observed, the book is singularly free from errors, albeit the author falls into the common one—common to catalogue and garden book alike—of spelling *Aubrietia* with one "i" only. We notice, too, that certain generic and specific names are hyphenated together without cause, as, e.g., *Hyacinthus candicans*, page 215, and *Lathyrus odoratus*, page 220, &c. The book is copiously indexed and well got up.

Chrysanthemums and How to Grow Them.†—There are thousands of cultivators of the "Autumn Queen," the amateur gardener devoting much attention to it and succeeding in producing every year extremely fine specimens, both as regards blooms and plants. New varieties are being raised every year, and nearly all require special treatment in order to bring them to perfection. Mr. J. L. Powell, the author, has given a great deal of very useful information in the book under notice. He

has studied the requirements of the beginner, advises him when to commence taking cuttings and how to propagate them. The period of growth under glass, the preparation of the soil, watering, and the science and practice of feeding are all subjects ably dealt with. Chapters are devoted to hints on growing plants to bear exhibition blooms, those for commercial purposes and the raising of new varieties. Insects, diseases and remedies are also dealt with. The chapter devoted to "Cultural Hints Month by Month" is one of the most useful in the book, especially to the beginner, and in a future edition the author would be well advised to extend it and give a few more details relative to the work of each month. The scale of points for judging plants is too high, namely: Equality of size and form of plants, 40 points; excellence of bloom, 35 points; foliage, 25 points; total, 100 points. To a novice this scale of points is apt to be bewildering. A total of 10 or 12 points would be sufficient, and half-points should be given. This part of the book should be revised as suggested. The photographs on page 66, showing the taking of the bud, are not clear enough to convey a conception of the work of bud-taking to a novice. These should be replaced by clearly-drawn sketches or better photographs in a future edition. The other photographs showing good and bad cuttings and how they should be inserted, also those showing how plants should be protected, are very good. The illustrations of individual blooms, specimens and groups in houses are very good and instructive. The author has ably dealt with border varieties as well as those for exhibition, and has given selections of varieties for various purposes. Chrysanthemum-growers will do well to purchase a copy of this useful book and study its contents.

Vines and How to Grow Them.*—The Grape Vine actually occupies only a small portion of this book, which is really devoted to references to a great number of climbing plants. "Climbing Plants and How to Grow Them" would have been a more appropriate title. This work is a fairly exhaustive one, dealing with climbing plants generally, both fine foliaged and flowering, and even Tomatoes are included. The author, Mr. William C. McCollom, deals in a very charming literary style with the uses and habits of Vines, when and how to plant, soil and cultivation, supports and trellises, pruning and management, insects and diseases, winter killing and how to prevent it. These are all very important points in the successful cultivation of Vines of all kinds. The book is lavishly illustrated, many of the photographs showing the different habits of the subjects under notice and their usefulness for covering old buildings, cottages, walls, trellises, pillars and stumps, as well as modern dwelling-houses. For such purposes attention is drawn to the proper use of the herbaceous perennial and the evergreen Vines respectively. Much very useful practical information is given; for example, in Chapter II., "When and How to Plant," the sub-titles are: Time to Plant, Spring *versus* Fall, Depth to Plant, Distance Apart to Plant, Transplanting, Holding Vines Over in Pots, Arrangement of Colours, Time of Flowering, Location. Some idea will thus be obtained of the useful information afforded. At the end of the book a list of Vines for special purposes is given, and also a planting table for Vines. In a single line the following appears relative to the Virginian Creeper: Botanical

name, *Ampelopsis quinquefolia*; common name, Virginian Creeper; height in feet, 50; kind of plant, hardy shrub; time of flowering; foliage Vine; colour of flowers; habit of climbing, tendrils and discs; when to prune, early spring; remarks, dozens of varieties, brilliant in fall. There are fifteen pages of such information given in tabular form respecting various kinds of Vines. This is quite an uncommon book, and will afford a vast amount of pleasure to all who become possessed of it.

Annals: Hardy and Half-Hardy.*—This is the twelfth of the "Present-Day Gardening" series being issued by Messrs. Jack, and of which Mr. R. Hooper Pearson is the editor. It is of a size uniform with those which have preceded it, and is written in a simple, practical style, dealing direct with the plants concerned in a really helpful way. The little volume—it is of about one hundred or so pages—is composed of some light-coloured plates of such typical examples as Zinnias, Marigolds, Sweet Scabious, Dianthus and others, and some five chapters dealing with "The Value of Annals," "Cultivation," "The Most Useful," those of "Less Garden Value" and "Selections," which in their several ways provide just that information which the plant-lover desires chiefly to know. Chapter IV., which treats of those "Annals of Less Garden Value," is of much usefulness—the separating of the chaff from the wheat, so to say—rather than to leave the amateur to flounder amid a host of kinds and varieties of which he knows little or nothing. It does not follow that those of lesser garden value have "neither charm nor comeliness, and no beauty to be desired"—far from it—nor does the author even hint at such a thing. But by placing them apart—setting them, as it were, on a lower rung of Popularity's ladder—the author, by awarding to them a second or third prize as distinct from the first or premier group in the case, has in nutshell form rendered a service to all who would grow these flowers. Too frequently in such books only the best is written of, and, of course, the best is good enough for all. But that that "best" might be secured to all, it is equally important that those plants of lesser value be brought into light, even if in negative degree. This, we are pleased to see, has been done. The arrangement of the plants throughout the book is alphabetical; the most ornamental of the species and varieties are given, together with cultural hints, the generic and popular names of each group appearing at the head. In these and in other ways the author, a well-known horticulturist and journalist, has done his part well. In a prefatory note we are rather surprised to see allusion to *Campanula pyramidalis* as an annual, the plant being of strictly perennial duration, often seen as a border subject and flowering annually. The plant, however, has a great decorative value if treated as a biennial. We have never seen it to be of service as an annual, and, indeed, it is not mentioned at page 27 among those of annual duration. We note, too (page 30), that the beautiful varieties of Corn Marigolds (*Chrysanthemum*) Eastern Star, Evening Star and others introduced by Messrs. Sutton are referred to *C. carinatum*, though obviously there is much external evidence of *C. segetum*. Such things are mere details, however, and in no sense diminish the value of the useful volume before us, which we commend to all flower-lovers.

* "A Year's Gardening," by Basil Harrave. Price 6s. London: Werner Laurie, Clifford's Inn, E. C.

† "Chrysanthemums and How to Grow Them," by J. L. Powell. Published by William Heinemann, London. Price 2s. 6d.

* "Vines and How to Grow Them," by William C. McCollom. Published by William Heinemann, London. Price 2s. 6d.

* "Annals: Hardy and Half-Hardy," by Charles H. Curtis; price 1s. 6d. London: T. C. and E. C. Jack. 67. Long Acre.

EDITORIAL NOTICES.

Every department of horticulture is represented in **THE GARDEN**, and the Editor invites readers to send in questions relating to matters upon which they wish expert advice.

The Editor welcomes photographs, articles and notes, but he will not be responsible for their safe return. All reasonable care, however, will be taken, and where stamps are enclosed, he will endeavour to return non-accepted contributions.

As regards photographs, if payment be desired, the Editor asks that the price required for reproduction be plainly stated. It must be distinctly understood that only the actual photographer or owner of the copyright will be treated with.

The Editor will not be responsible for the return of artistic or literary contributions which he may not be able to use, and the receipt of a proof must not be taken as evidence that an article is accepted. Publication in **THE GARDEN** will alone be recognised as acceptance.

Offices: 20, Tavistock Street, Covent Garden, W.C.

NOTES OF THE WEEK.

Garden Plans Competition.—In connection with the advertisement for plans for a small garden, which appeared in our advertisement pages some time ago, we are asked to state that the winner of the prize offered was Mr. Hugh R. Dixon, 73, Corringham Road, Golder's Green, London, N.W.

Phlox Frau Antoine Buchner.—This pure white Phlox has appealed to one very strongly this season, as much by reason of its handsome panicles as by its purity and good form. It is one to be noted for planting a little later, and, given good culture, will disappoint no one.

Roses in London.—It is by no means an uncommon expression to hear that Roses will not succeed in London, but this is not always borne out by facts. Just now in Hyde Park there is a bed of that grand variety Caroline Testout in first-rate condition, there being a good sprinkling of expanded blooms and a fine crop of buds to follow.

A Beautiful Clarkia.—When visiting the trial grounds of Messrs. Sutton and Sons at Reading a few days ago, we noticed a new Clarkia that is worthy of special mention. This is named Sutton's Double Scarlet, this name being derived from the colour of the flowers, which are a most pleasing shade of glowing rosy scarlet. It has a dwarf, compact habit, and each plant is freely branched, so that it is an excellent subject for the garden as well as for cutting. Grown in pots for greenhouse decoration in spring, this Clarkia would be very charming indeed.

Godetias as Cut Flowers.—Although Godetias are among the most prized of our hardy annuals for garden decoration, we do not remember seeing their merits as cut flowers brought to notice. Owing to the fact that the buds open well in water, Godetias last in good condition a long time when cut. We have had sprays of Lady Satin Rose and Double Rose, a beautiful pink variety, in water for ten days, and they are still quite fresh and pleasing. They are so easily grown from seed, which may be sown in autumn or spring, that they ought to find a home in every garden.

A Little-known Bulbous Plant.—One seldom sees the Puschkinias in flower in the garden of the average amateur. This is probably because one rarely finds a reminder of these little bulbs about the ordering-time, and this is our reason for penning this note at present. They are dainty Scilla-like flowers of graceful growth, as a rule, and of a pleasing white lined with a pretty blue. Of the few species, the one most usually offered is *P. libanotica*, of which there are two forms, *P. libanotica* itself and *P. l. compacta*. The latter is the more prized, but we are not sure

that we do not prefer the type, which has looser flowers. *P. scilloides* is sometimes offered, but one finds the names frequently interchangeable among bulb-dealers. The chief enemy of the Puschkinia is the slug, and bulbs should be planted in light soil about an inch or two inches beneath the surface.

A Notable Bedding Arrangement.—A tone of colour which has caught on with the fair sex of late is a peculiar yellowish terra-cotta. There is now in Hyde Park a couple of beds of a form of *Celosia pyramidalis* which is of just the fashionable tone of colour, and is thereby much admired. It is labelled *Celosia pyramidalis aurea*, but is of a distinct tone from the golden form usually met with. The plants are alternated with small examples of *Kochia scoparia*, and the bed is carpeted with blue *Lobelia*. The general effect is uncommon, but at the same time attractive.

Mesembryanthemum uncinatum.—In many directions this year, in Southern gardens, this pretty plant is flowering profusely, and it is as welcome as a flowering plant could be. The rosy pink flowers which terminate the branches are only rarely seen, and doubtless the great heat of the year 1911 has contributed not a little to their appearing now. The species is of shrubby habit and the whole plant of a glaucous blue, and when planted in a position of full exposure is quite welcome, even without flowers. It is well suited for the rock garden in the sunniest places.

A Beautiful Blue Alpine.—*Wahlenbergia vincaeflora* or *gentianoides* has been certificated under both names during the past few weeks, and is worthy of a note now (mid-August) because of its late flowering, a flowering which began in June and has never abated. Could any lover of alpines wish for more in a slender and graceful plant whose deep sky blue bell-flowers appeal to all? It loves a cool, sequestered spot, and looks exceedingly happy springing from a thin colony of the dwarfest of the crested Hart's-tongue Ferns, the dark green fronds being in delightful contrast to the rich blue flowers.

Campanula Stansfieldii.—This is one of the most valuable and easily grown of the late-flowering Bellflowers of lowly stature. Less dwarf than *C. pusilla* or *C. pulla*—for the plant may on occasion reach to 9 inches or so in height—it is yet of the pigmy class whose growth is of an ascendant character as opposed to those which trail. Pot-grown examples may have the horizontally-disposed bells of purplish blue dangling over the rim of the receptacle named, and very well they look. The plant is a profuse bloomer and most welcome in August. Culturally it might be suggested that it delights in a cool spot, where in sandy loam it will be quite happy.

CORRESPONDENCE.

(The Editor is not responsible for the opinions expressed by correspondents.)

Thalictrum dipterocarpum.—This is by far the most beautiful plant I have now in flower. It is about three years old, is over six feet high, and has flowers freely produced on longish stalks from the bottom of the plant. It is a most graceful plant, with its long, lavender-coloured flowers. I grow it in a rather damp and sheltered situation, though it has plenty of sun. It seeds and germinates freely, is easily reared and is quite hardy.—**GEORGE DIXON, Astle, Cheshire.**

Sweet Pea King White.—Although this fine new white Sweet Pea is not yet supposed to be "sent out," it has been exhibited in competitive exhibits this year, and, should it continue to show the same form, it will probably hold its own for a long time. As the writer has seen it exhibited it is a very fine flower in every way, and one which is likely to please all who like a white Sweet Pea—and who does not? I must say the name does not appeal to me, but that is nothing in the case of a lovely Sweet Pea suitable for all purposes.—**A. M. D.**

Eucalyptus globulus.—It is interesting to note that there are two fine trees of *Eucalyptus globulus*, commonly known as the Blue Gum tree, growing on the front of the Ilfracombe Hotel, Bournemouth. Both are long established, and have to be cut back each year owing to their rapid growth over the windows. They are about forty-five feet in height, of very good colour, especially the lower limbs, and very strongly scented. A little stream runs about fifteen yards from their base, into which they have thrown out their roots. They face full south, but are only slightly sheltered from the east winds.—**W. A. BATTERSBY, Bournemouth.**

Roses with Bad Habits.—The writer of the series of articles on this subject deserves the thanks of everyone who has experienced the difficulty of wading through long lists of names in the endeavour to find out a few that will give the best returns for garden decoration. With regard to Mrs. R. G. Sharman Crawford, my opinion is entirely at one with that of your correspondent, and though I have had some beautiful blooms, it is so liable to mildew that it will have to go. General Macarthur, too, is this season nearly as bad with mildew as the other, and on this account alone I am seriously considering its banishment. Killarney also gives a lot of trouble in this respect. Roses that hang their heads are also a nuisance in the garden, however fine the blooms may look when they are on the exhibition table—the worst of all places from which to make a selection of garden Roses. The fact is that Roses are now far too numerous, and an article from someone, such as your correspondent, on "Too-much-alike Roses" would be of great service to many.—**H. P.**

Judges Judged.—While the consensus of opinion as given on page 410 of *THE GARDEN* conforms to the principle set forth by Mr. John Wright, V.M.H., that "a judge must act strictly within the wording of the schedule," which judges of experience never for a moment doubted, I should like to add a further word as to recommending prizes. At the Sweet Pea Show what surprised me most of all was that the judges, immediately following their wholesale disqualifications, should append, or cause to be appended, to the class card a smaller one bearing a legend "recommending"

the prizes to the adjudged premier exhibits. This, of course, is a totally different thing to recommending "special" or "extra" prizes in certain cases where disqualification had been rendered necessary through error or oversight. In the two classes to which these minor cards were attached the prizes were offered for exhibits under emphatically-laid-down rules and regulations, and the judges in recommending the original prizes at all far exceeded their powers.—**E. H. JENKINS.**

— I have read Mr. Horace J. Wright's letter under this heading on page 386, issue August 3, and also the opinions expressed on the point by several eminent judges on page 410, issue August 17. I observe that the unanimous verdict is in favour of Mr. Wright's contention. My voice will be but as a whisper in the desert, I know, because I cannot aspire to such fame as the men who have already written. However, may I say a word for the judges who are alleged to have erred? Than our gardening judges none could be fairer; it is immaterial to them who wins or who loses. They do their duty without thought of pleasing or displeasing this or that exhibitor. But when it comes to the question of wholesale disqualification, as in the case at the National Sweet Pea Society's Show, out of which this controversy has arisen, I think that they are right to pause. I praise them for it. The rule was there, "double standards will disqualify." Did any of the exhibitors knowingly put in flowers with double standards with the deliberate intention of defrauding the society? I say, most emphatically, "No, not one of them." Should they, then, all be punished in the severest manner known in the show tent? Again I say "No." Had the judges thought the intentions of the exhibitors were bad, they would have had to disqualify; but accepting my view that the double standards were there in simple error, they took the lenient and, in my opinion, correct course. To adhere strictly to the letter of the law in such a case is to take too high a hand. From his notes in a previous issue of *THE GARDEN* I gather that Mr. Horace Wright has not forgotten an earlier occasion of disqualification in the history of the Sweet Pea Society. Does Mr. Wright know that his arbitrary action in insisting upon the rules being strictly interpreted almost wrecked the society on the threshold of its useful and prosperous career?—**H. R. H. T.** [We understand that the committee of the National Sweet Pea Society will not accept the judges' recommendations that prizes be awarded to exhibits containing double standards.—**ED.**]

Roses Lady Gay and Dorothy Perkins.—My experience of Lady Gay and Dorothy Perkins is exactly the same as the Scotch gardener's described by "Sub Rosa" in *THE GARDEN* of August 10, page 398. Dorothy Perkins grows strong and well, and bears beautiful large trusses of deep pink blooms, each bloom double the size of my Lady Gay, which comes paler, smaller, and does not look healthy in the foliage either. It is in rather a hot, dry position, and perhaps this may be the reason, for a neighbour of mine close by here finds, like "Sub Rosa," that Lady Gay does best for her in every way. I wonder whether the growers always name them rightly.—**ESSEX READER.**

— Several years since I planted some Roses of the variety Lady Gay from pots. These Roses were not very healthy when planted, but good soil was prepared for them, and it was thought that they would quickly root into this and improve in appearance. Our expectations in this respect

were, however, not realised. The plants made but poor growth, and this was not at all robust. The foliage was weak and sickly. I attributed this at the time to the plants being raised from unhealthy stock and grown rapidly under glass in strong heat. (It was soon after the Rose was in commerce.) Rose Dorothy Perkins, purchased at about the same time and from the same firm, was in every way satisfactory. I think Lady Gay is more robust, and produces a more uniform supply of flowers when budded. Own-root plants of this Rose should, if grown at all, be propagated from only the very best and strongest shoots. Dorothy Perkins can be grown on its own roots with every success. My experience has also been that the latter Rose will succeed in soil too poor to produce good flowers on Lady Gay, while the latter will grow and flower profusely without the amount of sunshine which seems absolutely necessary to the welfare of Dorothy Perkins.—**C. R.**

Laburnum alpinum.—I think "B." issue page 399, is quite right in calling attention to this Laburnum. The reason, perhaps, why one does not meet with it more frequently in small gardens is that its good qualities are unknown, and the common Laburnum is, of course, always sent out by nurserymen when a Laburnum tree is ordered, unless a special variety is asked for by the purchaser. In addition to the good qualities of the Scotch Laburnum mentioned by "B.," an important point with many having gardens by the sea or in exposed positions is the hardness of this variety. I can recommend Laburnum alpinum as a plant to grow by the sea in moderate shelter. The pyramid form is the best to plant, and the trees must be staked and made quite secure at the time of planting. It is almost impossible to secure standard trees in very exposed places. It is much better to start with small trees. The Laburnum is not fastidious as to soil, but prefers a good loam and thorough drainage.—**COLIN RUSE, Lambay Island, Rush, County Dublin.**

A Good Culinary Pea.—In reference to Mr. C. Turner's successful experience with, and recommendation of, the culinary Pea known as Veitch's Prestige on page 398 of *THE GARDEN* for August 10, I may perhaps mention the success I have experienced this year with a variety introduced by Messrs. R. Veitch and Son of Exeter and known as Western Express. This and another variety sent out by the same firm called Glory of Devon received awards of merit from the Royal Horticultural Society, the first in 1902 and the second in 1899. I have grown both kinds, and consider the flavour of Glory of Devon somewhat better than that of Western Express, though there is very little to choose between them, for both are excellent. Western Express is classified as one of the first-early sorts, and Glory of Devon as a main or middle crop Pea; but this year I have grown the former variety only, making three successional sowings, the first at the end of January and the others followed by intervals of two or three weeks. The rows ran north and south, so that the plants got the full benefit of what sun there was, and of rain there has been no lack. All the sowings bore an abundant crop of large pods containing on an average nine large seeds, but a good many of the pods bore ten seeds, so that the yield on shelling was very great. This, combined with the heavy cropping and the continuous supplies of the successional sowings, left no desire for growing other kinds.—**J. R. J.**

THE FLOWER GARDEN.

THE SPORTING OF CALIFORNIAN-GROWN SWEET PEAS.

Fremontia californica.—This is a fine shrub which deserves to be planted more freely in slightly-sheltered positions, for when seen with its numerous showy yellow flowers it is indeed a grand sight. It was originally discovered by Colonel Fremont in 1846, and the first plant to flower in this country was raised from seeds collected by Mr. Robert Wreneh, who sent them to the Chiswick gardens of the Royal Horticultural Society. Eventually, William Lobb secured seed, when plant-collecting in California, and from these a number of plants were raised, which were in due time put into commerce. Propagation is effected by cuttings, which are placed in sandy soil and kept under a bell-glass till rooted. At East Burnham Park, the country residence of Sir Harry Veitch, it is planted against a wall, where it is allowed to grow naturally, and not treated in the same way as most shrubs in a like position. Under these conditions it flowers annually.—S. T.

Snapdragons and the Rock Garden.

—The little note on this subject in your last issue (page 409) serves to remind one that there are at least two alpine *Antirrhinums* invaluable for planting in the rock garden. One of these, *Antirrhinum glutinosum*, is a low-growing or trailing species found growing wild in the Spanish mountains. The flowers, which are of a dull yellow, are produced in July and August, when most alpine plants have long completed their good display. The other species, *A. sempervirens*, is even more attractive, and flowers about the same time. It is a native of the Pyrenees and readily adapts itself to cultivation, as is clearly evidenced by the free-flowering colony shown in the accompanying illustration.—SPARTAN.

Zonal *Pelargonium Maxime Kovalsky*.

—A bed of this *Pelargonium* at Hampton Court arrests attention, especially at a little distance, by reason of its distinct tone of colour, which is a kind of 'yellowish scarlet or soft orange, difficult indeed to describe, but very attractive. Like many other good kinds—Paul Crampel, for instance—it was distributed some years before its merits were recognised, as it was sent out by MM. Lemoine et fils of Nancy in the spring of 1906,

and was given an award of merit by the Royal Horticultural Society last year. Apart from its value for bedding purposes, it makes a good pot plant, as the flowers, which are borne in large trusses, are of good shape and possess a certain air of refinement. Taken altogether, it is one of those varieties which, if not already grown, may well be noted for future additions.—H. P.

FORTHCOMING EVENTS.

August 27.—Royal Horticultural Society's Exhibition at Vincent Square, Westminster. Lecture at three o'clock on "Recently Introduced Water Lilies" by Mr. J. Hudson, V.M.H.

August 29.—Warkworth Horticultural Society's Show. Sandy Flower Show.

August 30.—Dunfermline Flower Show (two days). Highland Horticultural Society's Show.

August 31.—Flower Shows at Whaley Bridge, Jedburgh, Melrose and Symington.

DURING the present year there have been numerous complaints about the sporting of Sweet Peas, or, rather, many who have grown them have bluntly stated that the stocks were mixed, and naturally attributed the trouble to the carelessness of the vendor. Under the circumstances it was not unreasonable to do so, because such varieties as *Etta Dyke* and *Clara Curtis*, which have hitherto come absolutely true, have been giving a large percentage of rogues. Knowing as we do the vast amount of trouble that all reputable growers of Sweet Peas take over their stocks, we could not countenance such suggestions; and after making

matter a little further, this theory will not hold water.

There are two facts that induce us to arrive at other conclusions. One is that practically all varieties with mauve, lavender and various shades of blue flowers come as true, and in some instances more so, from Californian-grown seeds as from seeds saved in this country. Now, if the seed-growers in California were careless over some varieties, and allowed them to become mixed, it is only reasonable to assume that they would sometimes be lax with the blues.

Another, and even more convincing, point is that although the seeds may all be true, the resultant plants give the percentage of rogues already stated. Take, for instance, the two varieties *Etta Dyke* and *Clara Curtis*. It is well known that both have cream-coloured seeds, yet, although all the seeds may be this colour, the plants from Californian-grown seeds give a number of coloured

A BEAUTIFUL ALPINE SNAPDRAGON (*ANTIRRHINUM SEMPERVIRENS*).

enquiries in several directions, it would appear that the whole trouble is due to Californian-grown seeds. It is, of course, well known that a great many Sweet Pea seeds offered for sale in this country are grown in California, where the climatic conditions are usually much better for seeding Sweet Peas than in this country, a perfectly legitimate proceeding so long as stocks can be retained true.

We have seen instances during the last few weeks of Sweet Peas that were true when sent out to California to be grown, yet when the seed from these plants was grown in this country it gave from 10 per cent. to 15 per cent. of rogues. As already stated, this has happened with such varieties as *Etta Dyke* and *Clara Curtis*, which invariably come true in this country. The natural conclusion that the layman would come to at this stage is that the trouble is due to the growers in California, who have allowed the stocks to become mixed at seeding-time. But when we investigate the

flowers which, if due to mixing at seedtime, should have had dark-skinned seeds. To carry this a step further we may mention that seedlings of *Etta Dyke*, when 3 inches high, showed dark tendrils and axils of their leaves—a sure indication that they would not produce white flowers—yet, when they were lifted, the seed that was still adhering to the root-stem had a white integument. Although all the seeds sown were of the true colour and shape, the resultant plants gave maroons, mauves, and several other colours of which even a novice could detect the seeds before sowing were it a case of mixed stocks.

The above facts, then, force us to one of two conclusions. There must either be something in the soil or climate of California that induces certain varieties of Sweet Peas when grown there to break or sport the following year; or there must be some insect or other agent, unknown in this country, which effects cross-fertilisation. The latter theory would appear the more feasible of the two. A

keen grower of Sweet Peas tells us that Major Hurst, who has had charge of the northern trials of the National Sweet Pea Society this year, has proved that if flowers of white or cream coloured varieties from separate plants are crossed, they will in some cases give a percentage of red or purple flowers, thus indicating that colour factors for red and blue may be lying dormant in those varieties. The whole subject is one of the greatest interest, not only to the grower of Sweet Peas, but to the seedsmen who sell them. If any of our readers can throw light on the matter, we shall be pleased to publish their letters, but we hope they will condense them as much as possible.

BULBS FOR AUTUMN PLANTING.

(Continued from page 416.)

Snowdrops and Winter Aconites.—I believe the whole secret of success with Snowdrops and Eranthis is never to let them get dried up. Anemone blanda, and apennina, too, lose some small fraction

never have I seen enough of it in any garden; and many still lack *G. byzantinus*, a robust beauty that, if planted in August in cool but not sodden soil, will flower from mid-December till February; 5s. 6d. will give us a garden picture of 100 of these lovely Snowdrops during that dullest of periods, and in most gardens it settles down and increases happily from year to year if planted early. *G. Ikarie* is quite opposite in character from the last, in that it flowers after most other Snowdrops, producing its great drop-pearl-shaped flowers above wide, deep green, Scilla-like leaves in March. Be firm with yourself, and mark and order both of these at once. If you are starting off for summer holidays, order just the same and select their places in the garden, putting in a label and instructing your gardener to plant them there *immediately* they arrive.

Crocus is the family that next suggests itself, and here a little outlay will bring you great joy. *C. speciosus* costs 3s. a hundred, and I cannot believe the money could be better spent. It is the least particular, as to situation, of all the Croci, and

with white anthers and rich orange markings in the throat; a good grower in sunny nooks. *C. Salzmanii*, from Southern Spain and Morocco, is yet quite hardy here, and a very robust plant, giving large lilac flowers in October. *Zonatus* generally sends up a few blooms in mid-September, and continues till October is middle-aged. It is very easy to grow, a rapid increaser, and is of a silvery pink colour that is peculiar to itself. When these kinds are passing away, *C. longiflorus* comes into bloom, with its fragrant rosy lavender flowers. I am very fond of it, as it makes a wonderfully good mass if left alone for three or four years, and flowers so freely that it is one of the most effective of all when open in the sunshine.

There are many others worth growing—*asturicus* in several varieties, light or dark purple; *nudiflorus*, so plentiful in the Pyrenees that almost any plant you dig up brings corms of the *Crocus* with it, yet not often to be found in lists. But when found at a reasonable price it is quite a plant to acquire. Its large flowers are of a fine blue-purple and very handsome. *Medius* is not often seen in gardens, but half-a-crown will buy a dozen, and a dozen of its rosy lilac stars, wide open, showing the exquisitely pencilled throat and the rich scarlet stigmata like tassels of silk, will set you to saving up another half-a-crown or two for a further purchase another season. All these I have mentioned are reliable hardy kinds that should grow well in any garden worthy of the name. I cannot write any more, for it is time to practise what I preach and make out my orders for early planting.

E. AUGUSTUS BOWLES.

SEASONABLE NOTES ON AURICULAS.

Enemies.—Although it cannot be said that the enemies of the Auricula are numerous, they are persistent, and if left alone they will quickly ruin all the choicest plants in the collection. The grower who would achieve the greatest success must be prepared to give regular attention to the plants,

so that if an enemy does put in an unwelcome appearance it may be killed before it has had a chance to do material injury. The time demanded will not be much, provided that the examinations are made at frequent intervals and that they are thorough.

One of the worst pests, if it be not quite the worst, is the small grub that bores a minute hole in the bud and forthwith commences to eat out its centre. There is nothing effectual in regard to this other than incessant searching, and, as the hole is very small, close watch alone will reveal the presence of the enemy. When one is found, it will require no suggestion from me that it be immediately killed. It must be emphatically understood that this is an enemy which does not delight to show itself, but one that works insidiously, and must be sought for day by day.

Then it is well within the bounds of possibility that both slugs and woodlice are present in the garden, and if they can establish themselves comfortably in the Auricula-frame, they will do so and play serious havoc among the plants. Instant

PRIMULA MOLLIS, A LITTLE-KNOWN GREENHOUSE SPECIES FROM THE HIMALAYA. (See page 425.)

of vigour for every half-hour they are above ground, and I have never yet seen a garden that held too many of these treasures. Now, we will take such lists as Van Tubergen's from Haarlem, Barr's from nearer home, and T. Smith's from Newry, Ireland. What will the wise gardener mark for present planting? Zeal will mark much, discretion limit those marked to match planting space, and then, alas! the purse will have to cut numbers down to those it can provide coins for. *Eranthis hyemalis* costs 1s. 6d. per 100 from Holland. All should mark that with indelible ink, and the lover of strange plants might pencil a mark against *E. cilicica*. A dozen at 9d. are worth a nook in the rock garden or under a deciduous shrub, such as one of the choicer new *Deutzias*, for they flower when the old Winter Aconite is passing away, and their red stems and more finely-cut Toby-frills make a pleasant contrast with the older plant. The Snowdrop or *Galanthus* clamours next for early planting. I need not say anything in favour of the common single Snowdrop—it is, surely, too well known and loved to need my praise—but

will live and flower even under the shade of trees. Its flowers are large and stand up well, and are as blue as any known *Crocus*. The groundwork of most forms is really best described as blue, not *Nemophila* or *Delphinium Belladonna* blue, of course, but much bluer than many *Campanulas* that are so described. Then it is veined with a wonderful branching pattern of purple-blue veins, and outside, at the throat, is freckled with purple, and the stigmata are of a rich orange yellow that contrasts in a delightful way with the surrounding blues. On a sunny day in late September or early October a clump of *C. speciosus* is as lovely a sight as one can ever hope to see in an English garden. They multiply rapidly in warm, well-drained borders, both by seed and by tiny offsets, after the style of the "spawn" of *Gladiolus*. The variety *Aitchisonii* is very large—one of the largest flowers in the *Crocus* family, in fact—and of a pale lavender blue, and flowers rather later than the type. There is also a white form that is good. *C. pulchellus* is another inexpensive and delightful one to plant, of a charming cool lavender shade,

death must be meted out to them if progress is to be satisfactory. The woolly aphid, which encases itself round the collar of the plant, will cause death unless it is promptly brushed away. As far as my experience goes, it is impossible to prevent this pest, no matter how admirably, intelligently and carefully the plants may be managed, and one must, therefore, be constantly on the watch for it to ensure its removal before it can have done substantial injury to its host.

Potting.—If all work in connection with the potting has not yet been accomplished, it ought to be put in hand and pressed forward to completion in the shortest space of time conducive to carrying out the details with proper care. If it can be made convenient, pots which are exceptionally deep in proportion to their diameter must be given the preference, as the Auricula prefers to drive its roots downwards rather than curl them round the sides of the pots, as is the habit of many plants grown in our greenhouses. Fearful and wonderful mixtures of soil were supposed to be essential to success with Auriculas in the days of yore, but modern ideas are different, for they rule that the plants thrive best when a compost of sweet, plain food is provided, and there is nothing superior to the finest fibrous loam, with perhaps a little of something to open it if it is much on the strong side, to bring satisfaction. Watering is always a matter that demands thought and care, and especially so immediately after potting, when the roots have not had time or opportunity to secure a hold of the fresh material. An excess then will spell souring, and it will require the utmost attention again to restore the plants to good health. On the other hand, dryness to the point of dustiness will also spell disaster, and the cultivator must, therefore, strive assiduously to find the happy medium—pleasant moistness.

Plants Growing.—In favourable conditions many plants are now making steady advance, and it is wise to encourage this by every means. Give water before the soil becomes really dry, and test the pots at least thrice a week to see that a further supply is given at precisely the moment when it will do most good. Any leaves which show the slightest signs of decay ought to be at once removed, as the trouble will inevitably spread unless this is done. The surface of the soil in the pots should be gently pricked over to keep it open at all times, as this facilitates and encourages the admission of fresh air. This goes far to maintain the roots in excellent health, and the soil in sweet condition. F. R.

A NEW GLADIOLUS.

Wonderful improvements have been wrought among late-flowering Gladioli in recent years, and this fact was forcibly brought to our notice at the recent exhibition of the newly-formed National Gladiolus Society. Many novelties of sterling merit were shown on this occasion. On this page we illustrate one of the latest creations, named Crown Jewel. It is a strong-growing variety, bearing exquisite spikes of salmon pink flowers with a yellow blotch on the lower petal. This novelty was shown by Messrs. Kelway and Son, Langport, and recently received an award of merit from the Royal Horticultural Society.

THE GREENHOUSE.

PRIMULA MOLLIS.

THIS half-hardy Primula deserves more extensive cultivation. It is easily raised from seed, and makes a beautiful foliage plant. The large lobed leaves are heart-shaped. The margins are waved, notched and roundly toothed. They are soft and velvety to the touch, and the rich green surface, being densely covered with soft, silky hairs, gives the plant a very striking appearance. The long leaf-stalk is also pubescent. The calyx in shape is like an inverted cone, and of an intense red colour; it is also hairy. The lobes are acute. The flowers are borne in umbels (three

A NEW GLADIOLUS; CROWN JEWEL.

to five) on a long hairy scape. The corolla, rose-coloured, stands well out beyond the calyx. The photograph reproduced on the previous page was taken by Miss Amy Cameron, Trinity, Duns.

Morelands, Duns.

JOHN MACWATT.

MALMAISON CARNATIONS.

(Continued from page 413.)

Watering.—It is perhaps here more than anywhere that that fineness of judgment so impossible to impart, yet so essential to success, is so desirable. Soils and temperatures are definable in words, while water and its application to such plants depends not only upon the latter, their size and vigour, but upon the season, upon environment and many other things. That the Malmaison Carnation is peculiarly sensitive in the matter of

watering, and quickly resents an overdose of it, all cultivators know quite well. Careful watering, therefore, is a matter of great importance at all times, and during autumn and winter the plants may go for days without requiring any. To some extent watering may be regulated by the active growth or otherwise of the plants, but in no case should water be afforded in dribbles or medicinal doses. If a plant is dry, water it thoroughly, *i.e.*, give it sufficient to moisten the entire body of soil, after which let it become dry again before any further supply is given. We take our meals at stated intervals; we drink when we are thirsty; and plants should be catered for in like manner, and studiously withal.

Potting On.—A solitary layer produces in the first season of flowering a single stem, and, if sub-budded, one large flower and around the base of the stem several shoots, each of which if retained would flower the following year if the plant be potted on. This second potting is called a "shift" in garden parlance, and differs in no wise materially from the earlier potting into 6-inch pots. The same soil mixture and similar precautions must be observed throughout, together with extra staking as required. The potting of the old plants should be done very soon after the flowering is over, providing the plants with a liberally large pot at the time. Few plants probably among soft-wooded subjects are of a more exacting nature than Malmaison Carnations, and a full measure of success is only meted out to those who attend to cultural details for twelve months of the year.

THE ROSE GARDEN.

BEST ROSES OF THE YEAR IN A SCOTTISH GARDEN.

LAST year we had a very fine show of Roses, but owing to the great drought and heat the blooms were very thin and ephemeral. At the same time, the wood, if less robust than usual, was beautifully matured, and in no previous season have the plants come so well through the winter. For the first time in a fairly long experience I did not find a single dead plant, and we cultivate, roughly, seven hundred or more. The spring here was exceptionally dry, only 1.78 inches of rain having fallen during April and May. June was very wet, which, however, just suited the Roses, as in this late upland district we can never have blooms of Hybrid Perpetuals and Hybrid Teas until July. Our only advantage is the possession of a good stiff loam and an abundance of stable-manure, and these are, of course, valuable assets when growing Roses. The first three weeks of July were, on the whole, fine, and the first crop of blooms was in grand condition. Without exaggeration, I have never seen a finer lot of Roses anywhere, and certainly 1912 has been by far the most successful season we have ever had here with the Queen of Flowers. I will now mention a few of the very best varieties for this cold district, in the hope that it may be of some interest to others who have a similar late locality to contend with.

General Macarthur.—Certainly the finest dark red garden Rose. This year the blooms were of

enormous size and gorgeous colour. It is delightfully sweet, has grand foliage and promises a very fine autumn display.

M. Paul Lede.—One of the finest light Roses I know. Slightly variable in colour; sometimes this rivals a fairly good Lyon. Why is this fine Rose so much neglected?

Lyon.—Much finer than ever before. As the plants age, the habit seems to improve. Always best in dull weather. Withstands rain fairly well.

Mme. Ravary.—The best yellow Rose here. A free and constant bloomer. Best in dull weather.

Juliet.—A fine grower, but rather shy bloomer with us. The colours are unique.

Marquise de Sinety.—Glorious colour, large flowers, but shy bloomer. It has grand foliage, but a rather straggling habit.

Lady Ashtown.—One of the best pink Roses. This season the colour was deeper and brighter than ever before.

Viseountess Folkestone.—This old favourite has fairly excelled itself this season.

Fran Karl Druschki.—Very fine indeed on a south wall, but, being later than the majority of bush Roses, was caught before opening, where grown as a dwarf, by mist and rain.

Mrs. W. J. Grant.—Finer than ever before. A delightful Rose when it succeeds, as it has done this summer.

J. B. Clark.—Wonderfully fine this year. Even as a dwarf is flowering freely and giving very large, perfect blooms.

Ulrich Brunner.—Very fine indeed. This variety never fails. It withstands damp better than most.

Salamander.—One of the brightest red Roses we have. Has been extra good this season.

Pharisaer.—Very fine indeed.

Mrs. R. G. Sharman Crawford.—Particularly fine. What a pity this Rose is scentless.

The last two are not yet (August 5) in bloom, but promise to be finer than ever before. Shower of Gold is a lovely thing and flowered freely, although only planted last autumn. C. BLAIR.
Preston House Gardens, Lintlithgow.

ROSES WITH BAD HABITS.

(Continued from page 412.)

Richmond is very deficient of petals, much more so than Liberty, and although it is perhaps a better grower, it does not please me so much as the old favourite. Until we have a better, Richmond will no doubt be planted largely, but I would advise all planters to be chary of accepting the glowing accounts of some Continental novelties said to be superior to Richmond and other reds, for my experience is that they are not.

Homere is almost a Rose of the past. We could endure its malformed flowers before we had so many lovely Hybrid Teas, but now it is not worth the space it will quickly occupy, for it is a prodigious grower. Going through the village of Hockley in Essex recently, I should think ten out of every twelve Rose plants seen were Homere, and they made no appeal to me, being devoid of colour and form, although I grant at times it is very pretty.

Dr. O'Donel Browne is much too vigorous to plant with ordinary Hybrid Teas, as a plant of it would spoil any arrangement where compactness of growth is desired. The same may be said of

W. E. Lippiatt, both superb in their individual bloom, but too near the Hybrid Perpetuals in growth to make good Roses for planting with the ordinary Hybrid Tea. I think it will soon be time to grade the various Roses according to growth, so that the planter may know just what to expect, and I would commend this suggestion to the publications committee of the National Rose Society. Such another Rose is

Mrs. James White, a very nice variety, but far too vigorous unless we treat it on the same lines as we do Mrs. Stewart Clark and such-like, that is, as pillar Roses or as free bushes. The ordinary Rose catalogue

does not differentiate between such Roses, which are described as being vigorous, with, say, Laurent Carle, which also is vigorous, but not of the rampant half-climbing order.

Mme. Melanie Soupert will yield quite a number of very uninteresting open blooms, although the buds and half-open flowers are so lovely. Of course, we can cut these off, but I think it is a fault in a Rose when it does not finish well.

Mrs. Arthur E. E. Coxhead is a superb Rose in every way save colour, and even this at times is all right, but generally it is a shade that fails to appeal to most individuals. The same may be said of

Exquisite, a most beautifully-formed Rose and of delicious fragrance, but the colour of the older flowers is of a dull magenta shade. I have seen this Rose superb in colour as well as form, but it possesses the bad habit alluded to.

Coming now to a few of the Rambler section, I think it is a pity raisers choose to ally unappropriate

A VIEW IN MR. ARNOLD WEISS' WATER-SIDE GARDEN.

Hugh Dickson.—A grand dark Rose of most exquisite perfume. A fine grower, with good foliage.

Mrs. John Laing.—Better than ever before, but, lately, spoiled by the rain.

Mme. Melanie Soupert.—A magnificent pale Rose. When half expanded the colouring is exquisite, and even when fully open most telling in the garden.

Captain Hayward.—Still one of the best dark Hybrid Perpetual Roses. A particularly free bloomer and highly perfumed.

Liberty.—Particularly fine this season. The blooms, if rather small, are of good substance and the colour brilliant.

Killarney.—Better than ever, and, so far, free from mildew.

Caroline Testout.—Still unbeaten as a pink garden Rose. Very fine indeed this season.

Clara Watson.—Colour and size of bloom much better than usual. A grand pale Rose.

Gustav Grunerwald.—Better than ever before. A really good Rose.

While the foregoing have been the cream of the collection this year, the following have also been good in every way: Le Progrès, S. M. Rodocanachi, Marquise Litta, Prince de Bulgarie, George C. Waud, Richmond, Mrs. David McKee, Mavourneen, Helen Keller, Dr. Andry, Frau Peter Lambert, Jeannie Dickson, Margaret Dickson, Paul Neyron, General Jacqueminot, Alfred Colomb, Betty, Exquisite, Gladys Harkness, Hugh Watson, La France (letter than for several years), Mme. Isaac Pereire, Mrs. Aaron Ward (very fine), and York and Lancaster.

Climbing Roses.—The best this season are Hélène, Una, Dundee Rambler, Ards Rover, Mme. Isaac Pereire, Climbing Caroline Testout, Grüss an Teplitz, White Dorothy and Dorothy Perkins.

THE PAVED ROSE GARDEN AT DRYNHAM, OATLANDS CHASE.

names with some of these. For instance, Longworth Rambler does not ramble in the ordinary sense of the word, and if any have planted it to cover an arch, they will have to wait. The same may be said of

Ards Rambler, a Rose more fitted for a pillar than to ramble on an arch.

Aglaia is a very shy bloomer, and one that needs great care when pruning. In fact, it deeply resents the knife or shears, and should be given a position where it may ramble away undisturbed.

Goldfinch is a good Rambler, but its name might lead one to suppose it is all golden in colour, whereas the clusters contain a lot of very pale, nearly white, flowers that detract much from the general effect. I thought we had a real good thing in the

Perpetual - flowering Crimson Rambler, but it is shockingly addicted to mildew, the clusters of bloom being quite marred by the fungus unless checked early.

White Dorothy, when going off bloom, changes to a sort of dirty pink, which is anything but attractive, and we are glad, really, when we can cut away the sprays.

Now, I daresay there are other Roses with bad habits, but I will leave it to others to bring their names forward, and I think a ventilation of this subject before planting-time arrives may save readers a considerable amount of disappointment. This list of Roses with bad habits is an extensive one. The first instalment appeared in *THE GARDEN* July 27; page 379, and no less than forty well-known varieties have been included. It is not claimed that this

list is a complete one, and readers are invited to express their views on Roses that may have been omitted. P.

A BEAUTIFUL GARDEN NEAR WEYBRIDGE.

The gardens at Drynham, Oatlands Chase, near Weybridge, possess many attractive features, and of them an extensive paved Rose garden is one of the most pleasing. Roses are favoured flowers with Mr. Arnold Weiss, the owner of this garden, for here

may be seen an admirable collection of Roses bearing evidence of suitable surroundings and good cultivation. Many old favourites, as *Caroline Testout* and *La France*, are observed, which in their season yield a profusion of flowers. The Rose-beds are bordered by a line of Carnations, and the Rose garden is separated from the pleasure grounds by a well-trained Yew hedge. In the centre of the Rose garden is a fountain and Lily pool, which is quite in keeping with its setting of flagstones. Leading from the Rose garden to the flower garden and pleasure grounds is a flight of steps made of old paving-stones, and no opportunity has been lost to render them attractive and in harmony with the beautiful surroundings. From a glance at the illustration of these informal garden steps it will at once be observed that between the chinks of stone and in every available niche such plants as Thyme, Arabis, Mossy Saxifrage, and Sea Pink or Thrift have been planted, and, more than that, have taken kindly to their surroundings, to which they are so well adapted. This is a phase of gardening both simple and beautiful, and it might often be applied with advantage in other gardens.

STEPS LEADING FROM THE PAVED ROSE GARDEN TO PLEASURE GROUNDS.

trees in the background enhance the beauty of the scene.

Many beautiful flowering shrubs are to be seen in these gardens, and Rhododendrons have been extensively planted in bold groups for early summer effect. We were much impressed by a grand plant of *Abutilon vitifolium*, which in early July was carrying a good display of its showy mauve flowers.

Not the least imposing feature of these gardens is a beautiful alpine and moraine garden, which at the time of our visit was still in course of construction. This rock garden was originally shown at the Royal International Horticultural Exhibition, where it was so much admired by Mr. Arnold Weiss that it was afterwards removed in its entirety to his garden at Oatlands Chase. These gardens are laid out with taste and skill, and are so arranged that an effective display of flowers or foliage may be had at all seasons of the year.

KITCHEN GARDEN.

SEASONABLE NOTES ON VEGETABLES.

Spring Cabbage.—The careful cultivator who appreciates the immense value of this crop in the early months of the year will now have at least two sets of plants, the earliest of which will be ready for their permanent positions, while the later are still in the seed-bed. Immediately a suitable piece of ground falls vacant, it must be prepared by the deepest and most thorough digging and the generous but judicious incorporation of rotten manure—a excess will spell sappy growth that will succumb to the weather; a shortage will mean poor progress and quality. Planting must be done firmly, and a distance of 15 inches, or even rather less, will answer both in and between the lines. The young plants in the seed-bed must be thinned to allow abundant space, and should be removed to nursery beds before they become crowded if the permanent position is not quite ready.

Harvesting Onions.—In a dry season the harvesting of the general crop of Onions does not present any serious difficulties, since they will finish off splendidly on the surface of the bed or on a gravel path; but after a wet period, such as we have experienced this year, rather more care will be necessary, as the plants are sappy. It is wise to be on the safe side in the matter of drying off, even though it involves more time and labour, because, unless the bulbs are thoroughly ripened, it is certain that they will not keep through the winter, no matter how favourable the place of storage may be. The best method of keeping them is in ropes suspended in a position where they will have unlimited supplies of fresh air with no damp; but if this is inconvenient, they may be stored in thin heaps in a dry, airy room. Frost need not worry the grower for a moment if the place is dry.

Winter Greens.—It is more than likely that the whole of the Broccoli, Kales, Savoys and Brussels Sprouts are now in their permanent quarters; but if not, the sooner the task can be finished the better. Indeed, it is already on the late side for most plants. After planting it cannot be said that they make serious demands upon the time of the grower, but they must in no circumstances be neglected, or they will inevitably show signs of it sooner or later. Frequent hoeing should be an inflexible rule, because at the same time as it admits sweet, fresh air to the soil, it prevents weeds from becoming established. It is by no means uncommon to see some of the plants growing too rapidly, and when this occurs the grower

the better, as the possibility of heating is reduced. It is necessary that the place of storage shall be absolutely frost-proof.

Autumn Onions.—There can be no question as to the importance of having a good bed of Onions from autumn-sown seeds, and now is the time to make a start in the majority of gardens. The most popular varieties for the purpose are the Tripolis and Roecas; but the best that I have tried for weight of crop, excellence of quality and long-keeping properties is Sutton's Globe, and those who have not grown it ought to do so. Although the seedlings will be ultimately moved from one position to another, the soil must be thoroughly prepared by deep digging and the intelligent incorporation of manure. It is imperative to success that the drills shall be made firm before the seeds are sown, and all weeds must be suppressed. H. J.

CLETHRA ARBOREA, A FREE-FLOWERING SHRUB FROM MADEIRA.

TREES & SHRUBS.

CLETHRA ARBOREA.

ALTHOUGH introduced in 1784 from Madeira, it was not until July 30 of the present year that the Royal Horticultural Society bestowed an award of merit upon this handsome shrub. Doubtless there are many other valuable plants of time-honoured reputation whose merits have not yet been recognised. This beautiful shrub, unfortunately, is not sufficiently hardy to warrant its cultivation in the open, except in favoured counties such as Devon and Cornwall; consequently it is usually grown as a greenhouse subject in inland gardens. The illustration on this page shows the pure white fringed flowers depending from the under sides of the branches in their usual freedom.

A RARE SHRUB.

(*FALLUGIA PARADOXA*.)

In both gardening and arboriculture an indispensable family is the Natural Order Rosaceæ. A rare monotypic genus belonging to this numerous plant race is the Mexican and New Mexican *Fallugia* or *Sieversia*, a low, hardy under-shrub of singularly graceful appearance. It has many small leaves of somewhat thick velvety texture scattered up its slender white twig, each twig terminating in a solitary virginal white bloom. The flower, characteristic of the Rose family, 1 inch or more in diameter, with its bunch of numerous golden-tipped stamens, is a combination of Flax-like grace, Roek Rose fugacity and texture, and wild Rose attractiveness. It thrives in a warm, sunny position in light, sandy soil, and is increased by the freely-produced seeds. To the lover of rare foreign plants a good specimen in full flower is a pleasing revelation, and is additionally valuable on account of its late flowering season, in early September. W. R.

should go over the quarters when the soil is just on the dry side and tread firmly down close to the stems. This will slightly check the root action and favour hardier progress.

Lifting Potatoes.—The lifting of Potatoes must be proceeded with as the tubers become ripe enough. It is, of course, conducive to excellence of flavour and keeping properties to leave them in the ground as long as possible; but there is always a danger that second growth will set in if the weather turns wet, and in that event the value of the crop will be considerably reduced. The tubers ought to be handled with the utmost care, and no attempt should be made to store them until they are perfectly dry, and even then the smaller the heaps

GARDENING FOR BEGINNERS.

A SIMPLE METHOD OF STORING FRUIT.

I NOTICE in your issue of the 3rd inst. an enquiry from your correspondent "J. C. Le S." asking if fruit could be kept in vacuum receptacles. Is it worth the trouble "J. C. Le S." suggests? If so, let him try it. I opine he would find, when once he opened these vacuum tins, the contents would rapidly succumb.

I have kept my fruit in a most satisfactory manner on lattice trellis stores, and have taken the trouble to make and enclose a plan of one which I trust you will understand and that it may be of use, which will afford me pleasure after the courteous and helpful replies you have always accorded to my enquiries. My stands are made from rough sawn deal (odd pieces, in fact), and are, as you will see, 5 feet by 5 feet by 2 feet 6 inches. I have kept Reinette du Canada on them until the middle of June, and attribute this success to the free air space all round the fruit, which must not, of course, touch each other. I keep mine in a dry attic, and, as you will note, every fruit thereon is visible there. You will note on the plan a rough perspective view of the stand, and it is important that the strips shown at the four corners should be added front and back to attain perfect rigidity. The whole is a knock-down arrangement. I fasten the triangular strips to cross bearers, preferably with string, tightly lacing it; but there are other means by which this can be done should the space between the triangular spines be too much or too little.

T. H. P. DENNIS.
Chelmsford.

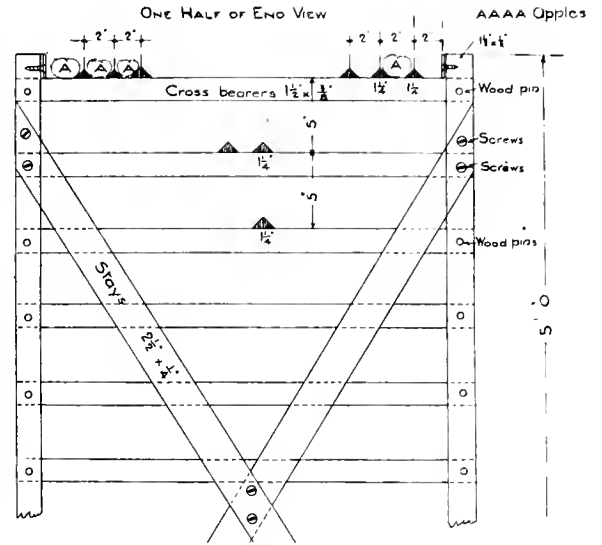

COARSE GRASSES ON LAWNS.

LAST year, owing to the exceptionally dry weather, many fine grasses died on

lawns, and the coarser and deeper-rooted ones spread considerably. Where the latter were left to make all the headway they could, they have now become very conspicuous on the lawn. There are two courses open to owners of lawns—either to wait until next winter before attempting to eradicate the coarse grasses and weeds, or to do so at once, to sow lawn grass seeds in a small quantity of new soil and have nice plants before winter comes. I strongly advise the latter plan. As long as the coarse weeds and grasses are left, so will the killing of the finer grasses go on; this must be so, as the big ones spread. Coarse weeds of all sizes may easily be killed by two or three drops of oil of vitriol in the heart of the plant. The oil of vitriol is a poison, and also burns the skin, so that due precautions should be taken. Uproot the coarse grasses,

put in some fine soil, sow grass seeds and roll well; also water if rain does not

and cropped for the first time this summer. In another ordinary digging or trenching would much

improve it, but the cultivator must lose no opportunity to get the soil into the best possible condition. In no case must the clayey subsoil be brought to the surface and mixed indiscriminately with the top layer for at least three years. At the end of that time, through yearly tillage, the soil to a considerable depth will be vastly improved, and some of the subsoil may then be mixed with the surface portion.

In many gardens there is a clayey soil and also a light one. In such cases the cultivator should, while carrying out trenching work, throw out spadefuls of the clayey subsoil at

a few weeks' time the lawn will have a greatly-improved appearance, and the work of renovation may go on during the winter months.

HOW TO IMPROVE GROUND FOR VEGETABLES.

EVERY year new plots are dug up and cropped with vegetables. In some instances the newly-broken soil is very good, and does not need much labour to bring it into a good condition for yielding first-rate crops; but in the majority of cases a good deal of labour is needed and much care in the working of the soil and the application of manures. There is no time better than the present for "taking stock," as it were, of the real state of ground which was broken recently

every few yards as the work proceeds, wheel it away to a corner of the garden, tip it down in rough heaps, and leave it there for the frosts and weather generally of winter to act upon it. One turning may be advisable about the end of January. By the end of April the stiff loam will be in a pulverised state and very suitable for mixing with lighter soil. The soil which is added must be kept near the surface, not buried, then it will still be under the influence of the weather. Rotted manure may be mixed with the clayey portion of the soil this autumn, and with the lighter portion next February. The pulverised clayey soil would be splendid for Roses. In the heavy soil Broad Beans, Cabbages, Cauliflowers and winter greens may be grown; and in the lighter soil Dwarf Beans, Peas, Beet, Celery, Potatoes and Carrots may form the principal crops. By judicious treatment from year to year the soil would be so much improved and enriched that very heavy crops could be obtained from it at a low cost as regards the tillage.

AVON.

GARDENING OF THE WEEK.

FOR SOUTHERN GARDENS.

The Rock Garden.

The Recent Rains that we have experienced have caused rather a sodden and bedraggled appearance, and considerably detracted from the general show of the few late-flowering subjects. Weeds have, however, grown apace, and careful hand weeding has been necessary. As soon as an improvement in the weather is apparent, the ground should be lightly forked up, and any places badly washed be surfaced with a compost containing plenty of porous material.

Cuttings.—Some of the subjects root very quickly, and any that show signs of having callused and rooted should be removed, potted if necessary, and placed where they may receive more air to prevent them becoming drawn, so that those which require it may be kept close and shaded from bright sun.

Fuchsia procumbens.—This is an interesting little trailing species that has flowered well this season. Unfortunately, here it is not quite hardy; therefore a few cuttings are best inserted at this season and wintered in a cold frame.

The Flower Garden.

Gaura Lindheimeri.—This is an extremely useful subject for the flower garden at this season, producing sheaves of flowers invaluable for cutting, while for continuity of flowering it is hard to beat. Seed sown in the spring will produce flowering plants the same season, but the second year gives a greater abundance, and the plants make dense growth and should not be planted less than 2 feet apart. Transplanted seedlings may be planted out in their permanent quarters now, and will be found quite hardy.

Chrysanthemum maximum.—The varieties of these have been particularly fine with us this season, and have made a wonderful show in the borders, while for cutting they are indispensable. Of the large-flowering varieties *The Speaker* is undoubtedly the best, the size of flower, length and strength of flower-stem exceeding any other variety with which I am acquainted. *Chrysanthemum maximum Daviesii* has small flowers, but is very free and useful.

Cosmeas.—These are among the most useful annuals that we grow at this season, and where cut flowers are in request the three varieties should be grown. They also make charming table decorations. The plants make good growth if planted in the shrubby border and a little attention is given at planting-time to fork up the soil and add a little decayed manure. Each plant should be afforded a neat stake, to which the principal growths should be looped up occasionally, otherwise they may suffer damage from winds.

Pyrethrums.—No delay should now be allowed as to any attention that may be necessary as regards division or replanting of these in the borders. If the plants are not split up into too many pieces, they will be found to thrive much better than if left till the usual season for attention to the borders.

The Hardy Fruit Garden.

Strawberries.—As soon as the runners have become well rooted in the pots into which they were layered, they may be planted out into the open ground where it is intended for them to fruit as soon as ready, and thus get well established before winter. The ground should be in good condition, and the bed allowed to settle before planting out. Knock out carefully from the pot and plant with a trowel in straight rows, leaving 18 inches between the plants and 2 feet between the rows.

Black Currants.—These require but little pruning beyond keeping the bushes within bounds and the removal of some of the oldest fruiting wood to encourage the younger growths and a shapely tree. Before long any attention that may be needed as regards staking should be given the plants, and the quarters of these and other bush fruits must be kept clear of weeds by occasionally going through them with the draw hoe.

The Kitchen Garden.

Onions.—The culture of large Onions is now fairly general, and apart from their value for exhibition purposes, they are valuable for use

in the kitchen. To ensure their keeping qualities a little care is necessary in the proper ripening and harvesting of the bulbs. No further stimulants must now be given, but by taking off the rough outer skin and so exposing the bulb to the sun and air, perfect ripening is afforded. Any signs of splitting can be further prevented by partially lifting the bulbs with a fork. When lifted, place on a soft layer of wood-wool or hay and lay out of doors when dry till thoroughly ripened, when they will be found to keep sound for a very long time.

Parsley.—Make a sowing in a sheltered position in the garden for lifting and planting in skeleton frames for winter use. Thin earlier sowings as necessary, and if the weather is showery, the thinnings may be transplanted out of doors with ease.

Runner Beans.—Keep the plants well supplied with water at the roots. When the growths have reached the top of the stakes, stop the shoots; this will cause the plants to break freely at the base. Keep the Beans picked as soon as fit, and if the foliage becomes too thick it may be partially thinned.

Plants Under Glass.

Fuchsias.—If plants are wanted for decorative purposes in the greenhouse next year, cuttings may now be inserted and struck in a warm house. Place four or five cuttings of half-ripened shoots in a 3-inch pot in a sandy open compost. When rooted, pot singly into small pots and move on as becomes necessary.

Humeas.—Seed may now be sown for producing next year's stock of plants. Sow the seed thinly in pans or direct into 3-inch pots and raise in a warm greenhouse. If the former way is adopted, pot the seedlings off as soon as large enough and avoid injury to the roots. Shade for a few days; after then expose to the light on a cool shelf and give more air.

The Greenhouse.—Keep the occupants in as healthy a condition as possible by sponging and occasional light fumigations. Many of the climbers will benefit if the growths are thinned out and regulated, and always endeavour to let them grow as naturally and gracefully as possible. The plants will greatly benefit, both in health and appearance, by an occasional rearrangement, washing the pots and the surroundings and raking over the base, whether of ashes, gravel or other material.

E. BECKETT, V.M.H.

Aldenham House Gardens, Elstree, Herts.

FOR NORTHERN GARDENS.

The Flower Garden.

Propagating Geraniums.—It is usually about this date before cuttings of Geraniums can be taken without the risk of making the beds unsightly. There is yet plenty of time to strike them for them to become established before the winter. My plan, after taking the cuttings, is to dress them ready for insertion in cutting-boxes; then leave them to dry for about two days, after which they are dibbled into the boxes.

General Work.—There is no intermitting labour in picking off decaying leaves and flowers and keeping gross-habited plants within bounds. The beds and borders should be examined for this purpose at least once a week, but twice a week would be better. Weeds have been extra troublesome, and extensive herbaceous borders, on account of the wet, had to be hand weeded three times. These, however, where the plants are closely planted, are now a negligible quantity; but there is constant work in keeping the plants in order, particularly in removing old spikes and decaying flowers and cutting-in overgrown plants.

The Rock Garden.

Hesperis.—The double Scotch or French Rocket is a capital rockery plant where effect is an object. It has, however, a disagreeable habit of dying if left too long, and therefore annual propagation has to be resorted to. The plants should now be lifted and pulled to pieces singly, and these be planted in cutting-boxes and placed in a cold frame till spring, when each will be strong enough to produce a spike of flowers the ensuing summer.

Saxifrages.—The low-growing, spring-flowering species, such as *sancta*, *Rhei* and the muscoides,

flower more profusely when pulled to pieces and replanted in fresh ground, and this operation may be effected now or soon. The little clumps should be only a few inches apart to ensure the whole space to be covered. An easier way is to pull out pieces from the groups without lifting, dressing with finely-sifted rich soil. Offsets of the *pyramidalis* section may be taken and replanted forthwith, the single pieces coming to flowering size in considerably less time than when left on the parent plant.

Erinus alpinus.—This pretty little flower is sometimes unreliable, and needs to be raised from seeds at intervals. Seedlings sometimes appear among stones, and these, if necessary, should be lifted and rearranged. Odd corners of rough steps suit them well.

The Vegetable Garden.

Onions.—Winter Onions will be certain to need hand weeding and the ground stirred with some sharp implement. If any of the spring-raised crop is running to seed, pinch out the stem at once, otherwise the bulb will cease to swell. In some seasons the foliage is much infected with Onion rust, and perhaps the best way to treat this is to cut off the infected leaves below the diseased parts. If allowed to progress, it undoubtedly injuriously affects the keeping of the bulbs throughout the winter.

Cabbages.—It is too soon for the main lot of these to be ready to transplant, but any specially large seedlings, if transplanted in the course of the next week, may come in some weeks in advance of the general crop. Thin out small ones if too close in the seed-bed, and remove any weeds such as Groundsel and Chickweed.

Lettuces and Endive.—Continue to plant out seedlings of these as they become ready. One can never be sure which will come in most useful for winter and early spring cutting, early sowings in mild weather turning in too soon, while later ones come just right, though perhaps of no great value in late seasons.

Radishes.—A large sowing made in the course of the next few days will be of much value as a late crop. Sow quite thinly in finely-pulverised soil and thin out if the seedlings come too close, else the greater part will run to leaves. These, if all goes well, will produce roots to use over many weeks.

Hardy Fruits.

Gathering Apples.—Lord Suffield, Lord Grosvenor, Victoria and Golden Spire may be mentioned as varieties which, if heavily cropped, may have the more forward fruits gathered, when the later ones will be considerably enlarged in the course of two or three weeks. Irish Peach may be gathered in the same way, only the trees will need to be inspected every two or three days, and a watch should be kept on other early-ripening varieties, especially those favoured with a wall.

Pears.—Clapp's Favourite usually commences to ripen at this time, and, like *Jargonelle*, matures very rapidly, but is not so liable to rot in the centre as the latter. Dr. Jules Guyot is another fair-flavoured variety which must be watched. The fruit of this kind keeps rather better than the others named.

The Plant-Houses.

Pelargoniums.—Spring-struck plants of the decorative section should now be advanced enough to be repotted into 6-inch pots. Rough rotted turf, dried cow-manure and a little sand suit them well, making the material rather firm, especially that in the under part. Give abundant ventilation, and remember that aphid is an intolerable nuisance.

Calceolarias.—These ought to be advanced enough for 4-inch pots. A rather heavier compost than that advised above is suitable. Keep the plants as cool as possible, and damp or moisten under and about them. Dryness at the root is to be deprecated above everything. If aphid appears on the under side of the leaves, dust with Tobacco powder.

Cinerarias.—Six-inch and 7-inch pots should be used for the larger plants of these, using leaf-mould and old Mushroom-bed manure to the loam and potting loosely rather than hard. Give the plants plenty of space in the frames, the leaves after this potting coming large and demanding extra space; and it must not be forgotten that they will do much better in cold frames than anywhere up to November.

R. P. BROTHERSTON.

Tynninghame, Prestonkirk, N.B.

DAFFODIL NOTES.

SOME MODERATE-PRICED DAFFODILS FOR SHOWING.

BEFORE I begin my list I would once more urge the great importance of early planting. It makes all the difference in the world. I would like anyone who is sceptical upon this point to buy a dozen of Emperor and plant half of them as soon as he gets them and the rest two months later. Then, when April comes, I would ask him to note and measure the results. Early planting means vigour and size. It also means better health for the bulb and greater increase. Dealers are fully aware of this, and those who list the more expensive varieties generally put a note in their catalogues to the effect that about the end of August or early in September their sales for these will cease, as they will then plant what is unsold. In a garden border it does not matter so very much if this or that bloom is not quite as large as it might be. Nor when the prices are low is it so important to get all the increase we can from our purchase, nor is the health question of such primary consideration. The first point is hardly noticed, and the results of the second and third are soon put right by buying new ones another season. Not so with the expensive "show" ones. Size at an exhibition means much. Increase and good health denote an adequate return for the money laid out.

Having urged the importance of early planting, I am now going to take the Royal Horticultural Society's List, section by section, and call the attention of would-be buyers to some of the more moderate-priced bulbs that are included in them. The word "moderate" needs defining. For my present purpose it may be said to be anything between two shillings and two pounds.

Division I.a, Yellow Trumpets.—This is an easy section to provide for. Such kinds as Hamlet, Cornelia, King Alfred, Lord Roberts, Monarch, Mervyn, Outpost and Mrs. H. J. Veitch are all flowers of good quality, although as grown in my garden I cannot say they are every one of them very good doers. Monarch does fairly well, but Lord Roberts but poorly. In some gardens the reverse takes place. Mervyn has its years, one good and the next bad. I feel I must give such warnings to put people on their guard and to prevent them expecting every kind to do as well as the good old Emperor. Lesser-known ones are the Rev. R. D. Williamson, a deep yellow, valuable for its lateness; Golden King, a new introduction of last year, of which I think highly—it promises to be a good doer; and Cleopatra, later still than the Rev. R. D. Williamson, a splendid thing and of large size, tall and very refined. Messrs. Barr and Sons have an excellent picture of it in their 1911 list. Two very beautiful deep rich yellows, almost rivalling the still unapproached Maximus, are Goldsecker and Leiden Jar. I have not grown either of them, and only know them for their appearances at shows; but they are always described as vigorous and strong in trade lists.

Division I.b, White Trumpets.—This is a coming section. There are a fair number of most lovely things coming along—Ailsa and Countess of Stamford, for example, but they are very dear now. Even Florence Pearson, which is one of the most robust, is not a quick increaser, while White Knight, probably the most refined Daffodil in

creation, is a very slow one. This means prices are slow in coming down; but everything comes to him who waits, and we can now buy Mrs. Robert Sydenham, which is a good, well-made flower, with a somewhat long and narrow trumpet, for 30s. from Miss Currey, and Mrs. G. H. Barr for the same figure from Messrs. Cartwright and Goodwin. One of the best of all low-priced ones is Princess (12s. 6d.), which only seems to be listed by Mr. Wilson. It is not large, but is well formed. As I have just bought some myself, I feel I can recommend it. Another show bloom is Treasure Trove, price about half-a-sovereign. I think it will be a fair grower. In pots it is exquisite. Loveliness and Lady of the Snows are two good varieties. I see in looking over old notes the former has frequently caught the writer's eye.

Division I.c, Bicolor Trumpets.—When we leave the well-known Duke of Bedford, Weardale Perfection, Glory of Nordwijk and Mme. de Graaff we have very few of moderate price. Cygnet is one of the best. It is of the pale type, and has a long trumpet, strikingly rolled back at the mouth. Judge Bird is a glorified Empress. Coronet is a beautiful flower, by no means large, but very taking on account of the deep tone and the bold contour of its trumpet. Queen Emma, one of Messrs. van Waveren's productions, I have not been able to find in any British list. I cannot think why, as it is an exceptionally good bloom for exhibition. It is on the early side. So, too, is William Baylor Hartland, a huge flower, well formed. The perianth is ivory white and harmonises well with the trumpet. I had some remarkable blooms this spring that, had they appeared in the Narcissus committee room of the Royal Horticultural Society, would, I think, have secured it an award of merit.

Division II.a, Large Chalice-cupped Daffodils with a Yellow Perianth.—Blackwell, Autocrat, Gloria Mundi, Homespun and Lemon Queen are well-known types of this section, which, to tell the truth, I always find a little difficult to fill when I am getting my blooms together for a show. One naturally thinks there must be no end of suitable varieties, but there are not. Some day, when Cœsus, Queen of Hearts, Helios and such flowers as Tammerlane are within the reach of ordinary pockets, there will be plenty to pick from, for there are many now in existence, and these will in time find their way into the market. Solfatare, and more particularly Noble, are excellent in every way. Both are on the late side, and both have good form and substance. I consider the latter a very fine thing indeed, and one that will be a Daffodil as long as it lives. Marguerite Durand is now placed in this section. When it opens it looks like a Leedsii, which indeed it is, but as it grows older it takes on a peculiar shade of pale canary. It should be allowed to grow on the plant, and must not be cut in the opening bud stage. Giraffe is a plant of great vigour, and has solid-looking, overlapping perianth segments and a large expanded crown much frilled at the edge. Of those of lesser value I would pick Cœur de Lion, a fine flower in a young state, with an open reddish cup; Northern Light; and Red Cup, a notable flower, owing to the orange glow in the yellow perianth.

Division II.b, Large Chalice-cupped Daffodils with a White Perianth.—This is one of the easiest sections to fill if one had to show in a six or a twelve class. There are any number of good flowers. Taking the more expensive first, we have Bernardino, Fleetwing, Charles, Lady Moore, Great

Warley and Pedestal. Fleetwing, Pedestal and Great Warley are bicolors. Charles and Lady Moore are mentioned because of their very striking cup, which has a fairly well-defined broad band of red round the edge. I call them both very excellent substitutes for Challenger. They are both most effective in any collection, and, what is also good, they are very distinct from other varieties, although of the same look themselves. Whitewell has now earned itself a position, and it bids fair to be one of the most popular show flowers. Amber is of the Nelsonii type, with a fine bit of pale orange in its cup. Lady Margaret Boscawen and Brigadier are fine bicolors, the latter being the more pointed. Steadfast is even better, but it is very late. Orangeman, when it does well, is most effective, its hold, orange cup always standing out conspicuously.

JOSEPH JACOB.

(To be continued.)

NEW AND RARE PLANTS.

FIRST-CLASS CERTIFICATES.

Montbretia Star of the East.—Judged by the progress of the modern Montbretia during the past eighteen or twenty years, this remarkable variety has advanced by a single bound at least a decade from all its fellows, outdistancing the best of them in size—the individual flowers are $4\frac{1}{2}$ inches in diameter—in purity of colour-tone and refinement, and not less so in the great flat flowers, whose presence is as a blazing fire. In their opening hours the flowers assume an almost blood orange tone; later when more expanded, a paler, rectified orange colour prevails, which contrasts well with an almost primrose yellow base. The reverse of the flowers, like the oncoming buds, is of an intense red orange over all, so that from any point of view the variety is of the picture-making order. Not least among the many good attributes of this unique variety is its fine branching habit, which promises a long succession of flowers. We congratulate the raiser upon so signal a triumph, regretting that such an epoch-making plant has not brought more tangible recognition to the worker. Exhibited by Mr. G. Davison, Westwick, Norwich.

Lælio-Cattleya Glaucus.—A unique and very highly-coloured hybrid raised by crossing Lælia purpurata and Lælio-Cattleya rubens. Of perfect form and compact habit, the dominant colour of the flowers is a vivid ruby red, with bright yellow disc. The hybrid does not partake of the character of Lælia purpurata, and some doubt was expressed as to its parentage. Be this as it may, it is a striking novelty, and worthy of its high award. Shown by Lieutenant-Colonel Sir George Holford, K.C.V.O.

Lælio-Cattleya Godmanii.—This is quite a distinct hybrid, remarkable for its large crimson lip. The petals and sepals are of an intense rosy hue. Parentage: Cattleya Iris × L.-C. callistoglossa. Shown by F. Du Cane Godman, Esq.

AWARDS OF MERIT.

Kniphofia Unique.—In colour best described as a reddish scarlet K. Nelsonii, from which, indeed, it is a seedling. The plant is $3\frac{1}{2}$ feet in height, with all the freedom of flowering of the original species and with considerably improved vigour. We regard it as a welcome border plant of middle height, and one specially suited to massing because of its distinctive colour and free-flowering. From Messrs. Wallace and Co., Colchester.

Cosmos White Queen.—A graceful and elegant variety, quite pure in tone, that should be much

in demand. It is quite an acquisition. Exhibited by Messrs. Dobbie and Co., Mark's Tey and Edinburgh.

Rhodostachys andina.—An interesting Bromeliad from the Chilian Andes, whose rose pink flowers, crowded on a hemispherical receptacle, are rendered the more conspicuous by the orange anthers. The arching or recurving leaves are strongly spined, of a greyish glaucous green, and arranged in a dense regular rosette. This interesting plant is not a novelty, but one whose rare appearance in public calls for more than ordinary notice. Exhibited by Mr. J. T. Bennett-Poë, Chesbunt (gardener, Mr. Downes).

Lælio-Cattleya luminosa Mandarin (*L. tenebrosa* Walton Grange variety × *C. dowiana aurea*), from Lieut.-Colonel Sir George Holford, K.C.V.O.

Brasso - Cattleya Ilene (*C. dowiana* × *B.-C.* Mme. Chas. Maron), from Messrs. J. Veitch and Sons, Limited.

Odontoglossum Empress Eugenie (parentage unrecorded), from E. H. Davidson, Esq.

Odontoglossum nigrescens (*O. Edwardii* × *O. cirrhosum*), from Messrs. J. and A. McBean.

The foregoing awards were made by the Royal Horticultural Society on August 13.

FLOWER TRIALS AT WISLEY.

The following plants have been adjudged awards of merit at Wisley after being inspected by the visiting committee appointed for that purpose. The varieties are not necessarily novelties—some, indeed, are well known and largely cultivated—one object of the trial, apart from its informative character, being to confirm previously-expressed opinions and, in the case of the Violas, to set a hall-mark of merit on those varieties which, by their persistent flowering appear best suited to garden-decoration generally.

VIOLAS.

Edina (Dobbie).—Of rich royal purple colour, habit compact and dwarf, free-flowering, and generally regarded as an advance on the well-known Archie Grant.

Pencaitland.—A fine pure white with yellowed lip; good perennial habit.

Walter Welsh (Dobbie).—Colour rich golden, the flowers slightly rayed. Of rather tall growth, but almost indispensable for its colour.

Maggie Mott (Dobbie).—This well-known pale blue needs no description. It is indispensable to all lovers of the Viola.

Lavender Queen (Mr. Cuthbertson, Rothesay).—A good dark lavender blue shade, with rather conspicuous dark rays to the flower. Habit and freedom of flowering excellent.

Snowflake (Mr. Cuthbertson, Rothesay).—A splendid white-flowered variety with yellow eye, perhaps the best white self in the collection.

Jubilee (Mr. Cuthbertson, Rothesay).—Fine purplish maroon, free, and a good carpeter of the soil.

Mrs. Chichester (Mr. Cuthbertson, Rothesay).—White with mauve shading and pencilling. A most pleasing and effective variety.

W. H. Woodgate (Forbes, Hawick).—This is of almost plumbago blue colour, and as distinct as it is desirable.

John Quarton (Forbes, Hawick).—A good all-round blue of excellent habit and freedom of flowering.

Mrs. Davidson (Forbes, Hawick).—Blue with lilac red shading distinct

King Cup (A. Dickson).—Rich golden colour, free-flowering, and with a good carpeting habit of growth.

Bessie (A. Dickson).—White, shaded lilac, and with yellow eye.

Palmer's White (Mr. Palmer, Derby).—A sturdy-habited variety and a good yellow-eyed flower withal. Excellent in every way.

SWEET PEAS.

Mrs. Routzahn (Dobbie).—This is probably one of the indispensables of the cream pink section, and is an exquisite colour combine.

Tennant Spencer (Dobbie).—Rosy purple to purplish mauve. A fine handsome-looking flower, quite a top-sawyer in its way, and good for garden or exhibition.

Isobel Malcolm (Dobbie).—An ivory or cream coloured flower of exquisite quality wedded to a plant of wondrous vigour and freedom, as well as profuseness of flowering. Quite in the front rank.

Hercules (Stark).—This variety stood out well in the collection, as befits the giant it really is. It is of rose pink colour; in brief, a glorified Countess of rare substance.

Premier (Stark).—Intense crimson, with no traces of scorching. A remarkable and striking bit of colour, and probably unique in this respect.

HOLLYHOCK.

Newport Pink (for strain).—The long line of fifty-two seedling plants made a fine display, and were absolutely true to colour—a good rose pink. From Mr. Dreer, Philadelphia.

The following awards were made as the result of trials held at Wisley:

MELONS.

First-class certificates were granted to the well-known varieties Hero of Lockinge and Frogmore Scarlet, both sent by Messrs. James Veitch and Sons. An award of merit was made to Royal Favourite, sent by Messrs. Sutton and Sons.

MARROWS.

The following were each granted an award of merit; Bush Green, sent by Messrs. Barr and Sons; Moore's Cream, sent by Messrs. R. Veitch, Exeter; and White Bush, sent by Messrs. Nutting, Southwark Street, S.E.

ANSWERS TO CORRESPONDENTS.

RULES FOR CORRESPONDENTS.

QUESTIONS AND ANSWERS.—The Editor intends to make THE GARDEN helpful to all readers who desire assistance, no matter what the branch of gardening may be, and with that object will make a special feature of the "Answers to Correspondents" columns. All communications should be clearly and concisely written on one side of the paper only, and addressed to the EDITOR OF THE GARDEN, 20, Tavistock Street, Covent Garden, London, W.C. The name and address of the sender are required in addition to any designation he may desire to be used in the paper. When more than one query is sent, each should be on a separate piece of paper. Plants for naming should be clearly numbered and securely packed in damp grass or moss, not cotton-wool, and flowering shoots, where possible, should be sent. It is useless to send small scraps that are not characteristic of the plant. Letters on business should be sent to the PUBLISHER.

FLOWER GARDEN.

PEONIES GONE WRONG (*Northwood*).—The most probable cause of the blind buds is the great drought of the summer of 1911, which precluded the development of the crown-buds on which the flowering depends. We can only suggest a very generous treatment of the plants at the present time as a means of modifying an even worse state of things another year, watering and affording liquid manure to the plants with the greatest freedom. There have been so many failures with these plants this year that

we published a special article on this subject in our issue for July 13.

SWEET PEAS (*H. W. S.*).—Bud-dropping is as prevalent as ever this season in well-grown plants on rich soil. It is more than probable that when the plants settle down to free flowering the trouble will almost, and probably entirely, cease.

PINK (*R. de la Poer*).—A very pretty, and apparently distinct, variation of the common Mule Pink, quite worth perpetuating if freely flowered. We are assuming it to be a Mule Pink from the flowers alone, though, had you sent some of the growth, we could have given a more definite answer.

CARNATIONS UNSATISFACTORY (*H. W. S.*).—We should ascribe the trouble with your Carnations to excellent grown and severe disbudding. Vigorous plants must have an outlet for their energies, and disbudding to a limited number of stems with only one bud on each does not provide it; the flower comes either abnormal, as in your case, or coarse. Allow more flowers, and you will probably have them perfect.

LILY DISEASED (*M. C. T.*).—Your plants are badly attacked by the well-known Lily disease, which in some parts has been attended by dire results. All you can do at the present time is to collect and burn every atom of the diseased leafage or stem-growth, and at the end of July lift the affected bulbs, give them a sulphur bath, dry them, and subsequently transplant in a fresh position. In the ensuing year, should the disease reappear, syringe the plants at once with sulphide of potassium, 1oz. to two gallons of rain-water. As a preventive measure you might employ this once every ten days from March to June, wetting both upper and under surfaces of the leaves.

SWEET PEAS (*E. M. B.*).—The Sweet Peas are attacked by eelworm. It is doubtful whether anything that can be done will cause them to recover; but you might try earthing them and use a stimulating manure, such as nitrate of soda. It is very doubtful whether the making of a hole in a clay soil and filling with a lighter soil is a wise measure, for the hole is apt to act as a catch-pit for water and the soil to become waterlogged. Great care should be exercised to see that the drainage is always thoroughly efficient. Eelworms are frequently introduced with stable manure if it has not been well matured before use, and especially if it is from animals fed with Clover hay. The soil before it is used for growing Peas again should be turned right over, so as to bury the eelworm-infested part as deeply as possible, and dress well with potash.

TREES AND SHRUBS.

AMPELOPSIS (*M. H. W.*).—Without seeing the plant and the conditions under which it is growing, no definite statement can be made respecting the cause of the shoots dying off. Old plants are sometimes attacked by canker. Fortunately, Ampelopsis Veitchii is a particularly quick-growing climber. Your best plan will be to root out the old one in autumn or spring, work in some fresh loamy soil, and put in a strong young plant.

LIME TREES (*L. E. T.*).—The common Lime is one of the best trees for clipping and training as you suggest. It is also a quick-growing tree, and would soon form a screen. *Tilia petiolaris* and *T. dasystyla* are, perhaps, improvements on the common Lime, *T. vulgaris*, in some respects, for they keep cleaner, and the leaves do not turn yellow so early in autumn. Should you require an evergreen, you might plant Austrian Pine. The Horse Chestnut is also a good deciduous tree for the purpose, but it is somewhat heavier than the Lime.

ROSE GARDEN.

BLACK SPOT ON ROSES (*M. A.*).—Unfortunately, you can do little to check this pest now, as it has such a hold upon your plants. It may be kept in abeyance if the plants are frequently sprayed with sulphide of potassium from the commencement of their growth. It is not likely to spread much more, as the visitation is nearly always simultaneous. You should, however, persevere in having infected leaves gathered up and burnt, and in winter have about an inch of the surface soil removed and burnt.

ROSE LEAF-CURL (*Mrs. Mallock*).—We have noticed that this troublesome disease seems especially to attack Roses growing in light soils. It is generally supposed to be caused by an insect—one of the sawflies, but we believe it is a fungus. At present it seems to be a mystery as to its origin, but we believe it is brought into the soil upon roots of plants that have come from infected districts. We would advise you to transplant your Roses next autumn, giving them some good loam, and prior to replanting well wash the roots. Pick off all the worst leaves and burn them.

ROSES, MANURE AND INSECTS (*Miss E.*).—Sulphate of iron is not a desirable manure to use for Roses; occasionally its use improves the colour of the flowers, but there are much better and safer manures to use. One of the best manures for Roses is Tonk's manure. This contains a very small proportion of sulphate of iron. A quick-acting and valuable manure for present use is Clay's Fertilizer. Dissolve 1oz. in a gallon of water, applying twice a week. From what you say, the pale yellow fly is the winged form of the common aphid, or green fly. Spray with a nicotine solution or diluted quassia chips extract, made by pouring boiling water on the chips. Soft soap is a good safe remedy. The piece of plant enclosed may be Spinach; but, please send when in flower, and also enclose a leaf or two from the base, as these are different from those on the stem and are useful for identification.

EDITORIAL NOTICES.

Every department of horticulture is represented in **THE GARDEN**, and the Editor invites readers to send in questions relating to matters upon which they wish expert advice.

The Editor welcomes photographs, articles and notes, but he will not be responsible for their safe return. All reasonable care, however, will be taken, and where stamps are enclosed, he will endeavour to return non-accepted contributions.

As regards photographs, if payment be desired, the Editor asks that the price required for reproduction be plainly stated. It must be distinctly understood that only the actual photographer or owner of the copyright will be treated with.

The Editor will not be responsible for the return of artistic or literary contributions which he may not be able to use, and the receipt of a proof must not be taken as evidence that an article is accepted. Publication in **THE GARDEN** will alone be recognised as acceptance.

Offices: 20, Tavistock Street, Covent Garden, W C

NOTES OF THE WEEK.

Honour for a Nurseryman.—Mr. Henry Merryweather, head of the well-known firm of Messrs. H. Merryweather and Sons of Southwell, Notts, has been appointed a Justice of the Peace for the county of Nottinghamshire.

Our Rose Articles and Coloured Plates.—To avoid confusion, all articles written by our contributor who has hitherto signed them "P." will in future appear over the signature of "Dane-croft." In response to the request of a number of our readers, our coloured plates will in future be published as separate sheets. They will not appear on the cover except on special occasions.

Linaria alpina rosea.—This is one of the prettiest of alpine flowers now in bloom, and which has also been flowering for some weeks past. The flowers are coloured a rosy pink, which is in contrast with a rather rich orange-coloured palate. The glaucous grey of the frail, almost succulent leaves and stems is also a feature of the plant, which is well suited to colonising in stony soil on the rockery. Occasionally the plant is seen to do well on old limestone walls, and anywhere it is both pretty and distinct.

A Hardy Pelargonium (*P. endlicherianum*).—If only because of the distinct beauty of its rosy and white flowers and the fact that in favoured places it is one of the most profuse of summer and early autumn flowering plants, this, the only species of the genus possessing any claim to hardiness, is worthy of every care. In Southern or South-Western England the plant may be safe in the open; elsewhere it may be well to lift it each year. The species is one of comparative rarity, though growing moderately well in sandy soils.

A Beautiful Evergreen Shrub.—In those favoured gardens where *Desfontainea spinosa* will thrive it should be encouraged to the full, because of the rare combination of scarlet and gold with which its tubular flowers are robed. These, brilliant and exceptional as they are, appeal the more strongly by reason of the striking contrast of the dark olive green leaves, and which constitute so good a foil to the flowers. In short, this too-little-known evergreen shrub is a plant of wondrous beauty and charm.

Clematis chryscoma.—This very rare and exceedingly beautiful *Clematis* was many years ago known in this country, but was, unfortunately, lost to commerce. Recently it was reintroduced from China, where it was found in the high altitudes of the Yunnan Alps. It belongs to the sub-shrubby section, and is perfectly hardy. The four-petalled flowers are produced on 3-inch stalks from the axils of the leaves, and are 2 inches to 3 inches across, white, with a slight suffusion of rosy lilac. The foliage is slightly woolly, like the leaves of the *lanuginosa* type, and, growing only

about eighteen inches high, it promises to become a very acceptable pot plant. It is not yet sufficiently propagated to be put into commerce, but next year may possibly see it listed.

Saxifraga cæsia.—A nice tuft of this well in flower has just arrived from Switzerland, which says much for the lateness of the season there this year. Quite heavy falls of snow, we are informed, were experienced in early August, with much cold and wet. In this country the pretty white-flowered *Saxifraga* referred to usually flowers in June. It is one of the miniatures among silvery kinds.

A Double-flowered Tunica.—If not the plant for effective display at a distance, the pretty carpeter and trailer, *Tunica Saxifraga flore pleno*, is desirable because of the pinkness of its "rosy" flowers. Thin and wiry of growth—not enough of it to please some—it is welcome to those who like to have all classes of plants—some for display and others to interest—so that their rock gardens may contain food for the mind as well as the eye. This pretty plant asks for nothing more than gritty loam and a fairly deep root-run.

Variation in Black Currants.—At a recent meeting of the scientific committee of the Royal Horticultural Society, Messrs. J. R. Pearson and Sons wrote that their Black Currant bushes were similarly affected to those mentioned on page 385 of our issue dated August 3, but that the trouble was not due to pruning. A letter on the same subject was read from Mr. E. Ballard, who suggested that forcing by too much manure or too hard pruning was the cause of the "throw back," or sporting, in Black Currants, and that the trouble is common among the Worcestershire growers.

Tamarix pentandra.—This is one of the daintiest of July and August flowering shrubs, for in habit it is light and graceful, while its tiny flowers, which are a delicate shade of rose, are very pretty. Although the plant had been known previously, it was brought prominently to notice about eleven years ago, when it was figured in the *Revue Horticole* under the name of *T. hispida æstivalis*. Subsequently it was called *T. Pallasi rosea*, but it is now known under the name which heads this note. Growing 3 feet to 4 feet high, it produces plumose branches clothed with bright green leaves, and among these the flowers are freely interspersed, the upper half of each shoot being covered with blossoms. The plant is usually cut hard back in spring, thus enabling shoots 3 feet long to be formed each year, for it is from strong young shoots that the best results are obtained. The branches removed during January are excellent for cuttings. These, cut 9 inches long and placed in the open ground in a similar manner to Currant cuttings, root during the following summer, and in two years' time form excellent flowering plants. Good loamy soil suits this *Tamarisk*, which is equally useful for seaside and inland gardens.

CORRESPONDENCE.

(The Editor is not responsible for the opinions expressed by correspondents.)

Calceolaria hyssopifolia.—Under this name a kindly-disposed correspondent sent me in spring a *Calceolaria* which has given much pleasure during the summer, and it is still in flower in the open. I fear, however, that it will not prove hardy, as I find that it is a native of Chili and Ecuador. It is quite pretty, with its narrow, rather glossy leaves and yellow and canary flowers. It is of shrubby habit, and should be a good subject for growing under glass or for planting out in summer. Here it is about a foot high, but I am told that it will grow to 2 feet. It is not a new species, but is not to be seen every day.—S. A., *Dumfries*.

Roses Lady Gay and Dorothy Perkins.—With regard to the correspondence in your columns as to the relative merits of these two Roses, may it not be that the difference of opinion arises from the way the plants have been propagated? Some people strike these from cuttings. *Lady Gay* does not succeed well in this way, and the plants are not long-lived. Others work them upon unsuitable stocks. Grown properly, I do not think there is much to choose between the two, but I prefer *Minnehaha* to either. The blooms are a brighter pink and are carried in sprays instead of close clusters, giving a more elegant appearance. Also it is a splendid doer, either as a climber or standard.—A. H. PEARSON, *Lowdham, Notts*.

Sweet-scented Musk.—The old-fashioned strong-scented Musk with small yellow flowers used to be grown by nearly every cottager in the country, and I used to see odd plants regularly in windows. Possibly some reader of *THE GARDEN*, seeing and reading "A Regular Subscriber's" letter on page 411, issue August 17, will communicate with the Editor, and in this way disclose the whereabouts of some pots of real old-fashioned Musk. Some years ago I noticed a clump of it in a herbaceous border in a large garden I had charge of. It was under the partial shelter of a *Magnolia* tree, but it flowered freely every year. I fear this clump was accidentally destroyed by some of the workmen while making alterations in this particular border. Plants in pots will live and flourish for ten or fifteen years without being disturbed. Readers will be interested to learn, through the Editor, particulars of the plant in question. There is no difficulty in procuring plants of the non-scented Musk with small yellow flowers.—SHAMROCK.

—With reference to "A Regular Subscriber's" query as to sweet-scented Musk and the Editor's remarks thereon, I would also like to say that I have for some years past bought plants from numerous advertisers who pretended to have the scented variety, but in every case they were not scented, or very slightly so. I should, therefore, be glad if any advertiser or reader of *THE GARDEN* could inform me where I could get a plant of the genuinely scented variety. No doubt it is to be found somewhere, probably in a cottager's home or in that of a country nurseryman.—A. SAUNDER, 6, *Holmewood Gardens, Brixton Hill, S.W.*

Paulownia imperialis after Flowering.—The excessive heat of last summer, combined with favourable conditions this spring, were undoubtedly the chief reasons why *Paulownia imperialis*, with its huge spikes of lavender blue flowers, was such an

attractive feature during June of this year in the few gardens in which this handsome Japanese tree is grown. In most cases it would now be laden with an unusual crop of fruits, which are ovoid, acuminate, and about an inch long. These should be removed for the benefit of the tree, as they would take a lot of nutriment from it, and the seeds seldom come to maturity in this country. This operation should be done with great care, for quite close to the bunches of fruit the flower-buds are already formed for next season's display, providing they can survive the winter and late spring frost.—F. G. PRESTON.

Matthiola bicornis.—For a number of years it was my duty to supply many plants possessing fragrant foliage or fragrant flowers, and I was well served by this small but deliciously-scented flower. Like your correspondent the Rev. Joseph Jacob, who has drawn special attention to the plant on page 410, issue August 17, I used to scatter the seeds thinly on the surface of the soil and rake them in. At first I made the mistake of sowing the seeds too thickly; result—decay of overcrowded plants in bad weather. The present summer has been very favourable to this plant. On account of the flowers closing during bright days, I used to scatter a few seeds of *Mignonette* among those of the Night-scented Stock, as it is commonly called; and, furthermore, I have also had Zonal *Pelargonium King of Denmark* planted 2 feet apart in the same bed, so that there was never any lack of blossom in it.—B.

Sending Seeds and Plants Abroad.—Though an ardent American, I have for many years bought, and encouraged others to buy, seeds, bulbs and plants from British dealers and growers. This I believe to be a vital stimulant for our own growers and seedsmen. May I through these columns, however, give a word of advice concerning the best methods of sending from England to this country? The *Parcels Post* is the medium, the conveyor. Though an order must be divided into several parcels if the plants sent are of such character as *Delphiniums* or *Pyrethrums*, no method of transportation is safe except the *Parcels Post*. Under no circumstances should one permit the express companies to forward such an order. The delays in New York would almost invariably mean death to the piteous occupants of the box or parcel. To prove my faith by my works, I enclose a small picture of *Myosotis* from Sutton's seed in my garden last May. You are at liberty to publish it if you wish.—(Mrs.) FRANCIS KING, *Orchard House, Alma, Michigan*. [Unfortunately, the photograph, which depicted excellent plants, was not sharp enough for reproduction.—ED.]

Preparing Lobelia for Winter.—The hints given by "B." (see issue August 10, page 405) for preparing and keeping *Lobelia* through the winter are well enough so far as they go, but they do not go quite far enough; hence I make no apology for the following by way of supplementing them. For some years I had to provide any number from 25,000 or 30,000 upwards, and did it as follows. Quite early in August—sometimes in July—when the first flush of blossoms was past, the plants were cut down to within an inch of the soil, and the latter being lightly pricked up, the surrounding surface, as also the newly-cut-down plants, were given a mulching of finely-sifted, sandy and rather rich soil, which was subsequently gently watered to settle it down. With the lapse of two or three weeks both new growth and new root-fibres were abundant, and at any convenient time the plants

were lifted, divided up as freely as possible, and planted an inch apart in shallow boxes of rich sandy loam. Consigned to a frame—a manure frame with declining or exhausted heat for preference—and thoroughly watered, the young plants started into growth immediately, and, cut over with scissors once or twice subsequently, usually covered the boxes by October in much the same way as those bedded out in summer. I always found *Lobelia* so treated to delight in ample supplies of water, and to such an extent that the branches sent out rootlets with great freedom. In this way a large percentage of the early cuttings were of the Irish standard, *i.e.*, ready-rooted ones. Six or a dozen plants treated as above would be ample for most amateurs, while for the large number I had to provide, 100 plants always gave sufficient, and were planted in reserve for the purpose. The material difference of "B.'s" plan as compared to my own is that "B." relies upon the partly-resuscitated vigour of the old plants, while I go in for the creation of an entirely new plant, characterised by the freshness, vigour and growth freedom of youth.—E. H. JENKINS.

Judges Judged.—Having been asked to give my opinion upon this subject, I now do so, but quite irrespective of the case of the Sweet Peas that gave rise to the question. Every judge should do his best to correctly interpret the strict reading of the schedule as it pertains to the rules and regulations laid down therein. Wherever I have had any doubts upon this point, my plan has been to consult some responsible members of the committee. If a schedule be not sent me when I am invited to act as a judge, I always request that one be sent upon my acceptance of the invitation. Then, in my spare moments—possibly upon my journey, if not before—I read the schedule up and look out for all moot points in particular. These I carefully note and consult my colleague upon. Sometimes a rule may be read in diverse ways, either in favour of the exhibitor or in favour of the society. Such cases have to be well thought out. No judge should ever act without studying the schedule previously. When any society invites a judge to act, it is always better to there and then send a schedule so that it may be considered. After the awards have been made, more particularly in a keen competition, every judge should be able to give his reason definitely for the decisions arrived at if he be called upon to do so by the society. I do not, however, believe in doing this to every exhibitor without a cogent reason. No society should impose upon the judges any kind of work not immediately associated with the actual judging. By this I mean such as sticking on the awards or in any unnecessary booking. All this takes time, which is too valuable to be expended in such work. Judging should always commence to time. The exhibitors themselves are often to blame for any failure to comply with this regulation. Judges are sometimes called upon to do unpleasant things, such as where absolute deception has been practised with the intent to defraud. On the other hand, I have had to deal with instances of palpable oversight, such as staging nineteen plants instead of twenty, or in putting one more fruit of a Pear, a Peach or a Fig upon a dish. In these instances I have asked the committee to either set the matter right themselves, or call upon the exhibitor to do so himself. In conclusion, let me say that all societies should do their utmost to make the rules and regulations as plain and explicit as possible. Then the judges should do their best to comply with the same.—JAMES HUDSON, V.M.H.

Japanese Irises.—I enclose a photograph of Japanese Irises growing here on the edge of my piece of water. They have been planted now a good many years, and invariably do well. I have to protect them with wire from rats, which are very fond of the tuberous roots. You may like to reproduce the photograph in THE GARDEN.—**GEORGE DIXON, Astle Hall, Chelford, Cheshire.**

Coreopsis verticillata.—This bright little Coreopsis is at present very pleasing in the garden of Mr. James Davidson, Summerville, Dumfries. Its light and graceful foliage is always pleasing, and, when well supplied with the pretty yellow flowers, a good plant is among the most useful of the border plants of July and August. In this garden it is less than two feet high. Not so well known or so large-flowered as *C. lanceolata*, it is a more perennial subject in most gardens.—**S. ARNOTT.**

Begonia carminata.—Of late years a considerable amount of attention has been directed towards the shrubby-growing Begonias and their value for various decorative purposes. Varieties such as President Carnot and Luzerna have of late made considerable headway in popular favour, while the old *Begonia coccinea*, a tall-growing species from Brazil, with large, pendulous clusters of scarlet flowers, is, as a rule, much better grown than it used to be. Between this just-named species and the white-flowered *Begonia Dregéi* the variety *carminata* was raised some years ago by Messrs. J. Veitch and Sons; indeed, it was given an award of merit on July 9, 1895. For greenhouse decoration during the summer months it is of considerable merit, while its season of beauty often extends well on into the autumn. It forms a neat, bushy specimen, which will bloom freely when from 18 inches to a yard in height. The flowers, which are borne in drooping clusters, are of a pleasing carmine rose tint. This *Begonia* is readily propagated from cuttings, and the young plants so obtained grow away freely. As a greenhouse flowering subject it is one of the most useful, and is deserving of extended cultivation.—**H. P.**

JAPANESE IRISES BY THE WATER-SIDE IN A READER'S GARDEN.

THE ROCK AND WATER GARDEN.

PLANTING A ROCK GARDEN.

NOW is the time to plant a rockery, the earlier the better. It gives the plants an opportunity to become established before the winter sets in, and this specially refers to early spring flowering alpines, for they then give a better show of bloom. Where special care can be taken and protection given, rock plants can be planted in nearly any month of the year. A low rockery made in front of a herbaceous border or shrubbery can be planted to make a very effective display with dwarf alpines of bright colours

Easily-grown Alpine Plants.—Alpine plants, which thrive well in any ordinary soil, are not grown so extensively in small gardens as they ought to be. Alpines can be obtained in a variety of colours, including white and rose to deep red or crimson. *Dielytra eximea* has reddish purple blossoms in drooping racemes, with a groundwork of Fern-like foliage, which gives the plant a beautiful effect. *Draba* forms a beautiful carpet, and usually flowers in April. In *bruniceifolia*, yellow, and *dodeana*, snow white, we have two charming kinds. *Edraianthus* has flowers similar to the alpine *Campanulas*, bearing drooping, bell-shaped flowers of deep blue colour. *Epimediums* are charming rock plants, bearing small purple-crimson and yellow flowers and foliage of lovely soft green, which turns in the autumn to a most lovely bronze. Heath (Ericas), which prefer airy situations, are very useful for the alpine garden. *Genista tinctoria flore pleno* is a native shrub with slender branches and pretty double yellow flowers. *Gentiana acaulis*, too, with its intense dark glowing blue flowers, must not be forgotten. *Geum Rossii* is an acquisition, with its finely-cut leaves and bright yellow flowers, as is *Gypsophila prostrata*, beautiful in its spreading masses and loose, graceful panicles of white or pinkish flowers. *Iberis Little Gem* and *I. stylosa* are two neat varieties of Candy-tuft, and as white as snow. *Hypericum* (Rose of Sharon) must not be overlooked. *Hutchinsia alpina*, a neat little plant with shining leaves and myriads of pure white flowers, when established becomes a dense mass. It should be given an open position facing south. Last, but by no means least, are the *Helianthemums* or Sun Roses. No plants put forth brighter colours than these. They will grow in any soil, and are not particular to position, though they like sun for preference. There are many varieties, ranging in colour from pure white to the palest pink, sulphur to deepest yellow and orange, and deep rose to darkest red. Alpine *Phloxes*, *Campanulas*, *Sedums*, and *Viola cornuta* and varieties are all easily grown, and will thrive in almost any soil and position. J. L. E.

ALPINE FLOWERS IN SEASON.

Among many plants now in bloom none is more interesting than the

pretty *Campanula carpatica* White Star. This has large, pure white flowers of a very bold character, and makes an unusually fine display. It is growing in the moraine section.

Tunica Saxifraga alba plena is a pretty and quite an uncommon plant. It is very graceful and free blooming, and is making a fine show.

Lewisia Howellii is flowering for the second time. This is also in the moraine section. I might mention here that we have all the set, and these are growing freely and are apparently quite at home.

FORTHCOMING EVENTS.

September 4. — Carlisle and Cumberland Horticultural Association's Show and Fruit Conference (two days). Kelso Flower Show. Glasgow and West of Scotland Centenary Show (three days).

September 5.—Preston and Fulwood Horticultural Society's Show (three days). Dundee Flower Show (three days).

September 6.—Leek and District Horticultural and Agricultural Show (two days). Kilmarnock Horticultural Society's Show.

September 7.—Société de Horticulture de Londres Meeting. Chorlton-cum-Hardy Horticultural Society's Show. Waterhouse Flower Show.

and spreading habit. There are many desirable plants with very free-growing habit which will become as bad as weeds if left to themselves. These should occasionally be trimmed up. Permanent rockeries should now be weeded, and in uprooting the weeds care should be taken not to disturb the roots of the alpines more than one can help. To have a successful rock garden, always secure plants with as long a flowering season as possible. Many plants are far ahead of others in this respect, and a very careful survey should be taken of a good collection.

Pratia Arenaria. a small creeping plant, is growing and flowering in full sunshine, although many people grow it in shade.

Philesia buxifolia is flowering quite freely in a position sheltered from the sun. Its Lapageria-like flowers show up very beautifully.

Mitraria coccinea, in a similar position, is now a mass of flowers, the scarlet blooms showing to great advantage among its bright green foliage. It is quite a large plant, measuring 5 feet each way.

Opuntias in Variety have been, and are now, in great glory, and have produced a quantity of blooms. They are extremely interesting, so rarely do we find them in outside positions. W. A. Cook.

Leonardslee Gardens, Horsham, Sussex.

THE FLOWER GARDEN.

THE MADONNA LILY.

THE most prized Lily of the garden, as it is also the most chaste, is the beautiful Madonna Lily,

as it were, by an environment well up to the standard of merit of the subject itself.

Such work might reasonably be called "planting for effect," and certainly far too much is done without any such aim or object. In the case of this Lily, however, such positions as those indicated may mean something more, the drier, poorer soils playing their part in keeping at bay—to some extent, at least—a leaf disease which is not infrequently of an overwhelming character when the plant is grown in richer soils and in more open places. The Madonna Lily is so prone to fail in what one might describe a good position, and succeed in quite unorthodox places and soils of a very diverse character, that no definite rule can be laid down respecting it.

Years ago the plant seemed quite indifferent to heavy soils or light or partial shade or full exposure, if occasionally, apparently by great height or vigour, displaying a preference to soils of a rather holding nature. It was not always so, however, and a long tenure of the soil or the reverse had almost invariably played a part. To-day, however,

periodical transplanting is suggested—far from it, since probably no Lily better repays for being left alone. Many, however, delight in adding to their existing stock, and all such should endeavour to get the work of planting done during the present month or as early in September as possible. In this way root-fibres and leaf-growth will be encouraged to develop in their season, and in turn enhance the chances of success. To delay the planting till late in the season or till winter has arrived is wrong, and one object of this note is to prevent a recurrence of work destined largely to result in failure and loss. E. H. JENKINS.

SWEET PEA NOTES.

Coarse Flowers.—I have been pleasantly surprised at the comparatively few really coarse blooms that have come under my notice. The season has been one which would be expected to favour this in soils that were heavily dressed with organic manures and had concentrated fertilisers as supplements, but the fact remains that I have seen fewer than last summer. There have been unmistakable indications of disappointment at shows when flowers on stems 20 inches or more in length were passed over for those shorter and infinitely more refined; but the march of education is steady if slow, and it seems probable that the ungainly, floppy caricatures of Sweet Peas have ceased to meet the approbation of the majority of judges. This is as it should be, for when once we lose the gracefulness, elegance and refinement of the Sweet Pea, its claim upon our affections will be gone. The delicious fragrance that was so characteristic of the older varieties is nearly lost. In a mass there is distinct perfume, but it is not as sweet as that of old and, unless I am much mistaken, there is not nearly the penetration about it. One wishes that this could be retrieved, but, failing that, the other charms of the flower must be retained inviolable.

A Six-bloom Stem.—A regular reader of THE GARDEN is proud of a six-bloomed stem, but unfortunately he does not give the name of the variety which produced it. He writes: "I picked from my garden a six-bloom Sweet Pea on August 23. Each bloom was perfect and each had a separate stalk. My gardener

thought it uncommon, having never seen a six-bloom one before. The blooms grew on a thick, rather flat stalk of good length, and did not appear to be two stalks growing together." There seems little doubt from my correspondent's own description that the stem was a fasciated one. These have been by no means uncommon this year, and I have heard of several sixes.

A Surrey Record.—When one speaks of Surrey in connection with Sweet Peas, one's mind involuntarily turns to Addlestone and Mr. Stevenson's wonderful record as a grower and an exhibitor; but the reader to whom I wish to allude now is Mr. A. W. Lambert, gardener to Mr. P. E. Pilditch, L.C.C., Bartropp Lodge, Weybridge Heath. With an interesting letter came two photographs which, although they are not quite suitable for reproduction in the pages of THE GARDEN, show clearly that

MADONNA LILIES, WITH A YEW HEDGE AS A BACKGROUND.

Lilium candidum, which is known to all. Not merely is it the admired of gardeners and gardening folk, since the poets of all ages have sung its praises, just as the artist has loved to paint it or the sculptor to reproduce, so far as is possible, somewhat of a sculptured beauty whose uniqueness none will deny. The best of such representations, however, fall very short of the real thing, and probably must for ever remain as examples of a "base, awkward imitation." In short, no picture of it could possibly equal the garden picture at its best—albeit that "best" is but rarely seen—the effect is best when the planting has been of the thoughtful order and care has been taken to so arrange the clumps or groups in near proximity to Holly or Yew or other dark-leaved subject, so that all the good of which the plant is capable stands out in bold relief—mirrored and framed,

the best-informed cultivators are seeking after a sign, and the most that can be offered includes a position of comparative dryness and not a little warmth, in conjunction with shallow planting and unmanured soils. Doubtless the disease which almost swept this unique Lily out of cultivation a score or more years ago greatly weakened the stock, a weakness from which no complete recovery has been made. But while one may not lay down dogmatic rules as to soil and other things, one can at least speak with emphasis upon the all-important matter of the

Time for Planting or Transplanting.—So nearly akin to evergreen is the Madonna Lily that only a short period of comparative inactivity exists between the flowering and the reappearing of a new basal leaf-growth, and the work of transplanting should be done at that time. Not that

MONTBRETIA STAR OF THE EAST, A NEW VARIETY WITH FLOWERS $4\frac{1}{2}$ INCHES IN DIAMETER.

Mr. Lambert is an exceptionally skilful grower, and if he is not already a member of the National Sweet Pea Society and an exhibitor at its exhibitions, the sooner he remedies the fault the better it will be for his reputation. I am pleased to see that such excellent results are achieved at Bartropp Lodge on plants grown in the old-fashioned way on Hazel sticks. One picture shows a vase of three stems, including Mrs. Hardcastle Sykes with five blooms, Helen Lewis with six blooms, and Tennant Spencer with eight blooms, but the second and third named have every indication of being fasciated stalks. Mr. Lambert sends some interesting details about his collection, which comprises the best varieties in commerce, and I congratulate him on his success. His letter concludes with a reference to what he aptly describes as a Sweet Pea freak that carried no fewer than twenty buds.

Double Standards.—I do not suppose I shall be the first to inform the Sweet Pea loving public that the committee of the National Sweet Pea Society at a recent meeting decided that the prizes recommended by several judges for exhibits containing blooms with double standards should not be awarded. I am extremely glad of this. I am keenly alive to the disappointment that it will cause, but it is imperative that a society shall stand by the rules published in its schedule if it is to go on from strength to strength and retain the respect of its members. The point which we shall now await is the abolition of the rule or regulation which decides that the inclusion of flowers with double standards will disqualify. H. J. WRIGHT.

MONTBRETIA STAR OF THE EAST.

As described in our last issue, page 431, this remarkable variety has advanced by a single bound at least a decade from all its fellows, outdistancing the best of them in size, colour-tone and refinement. When shown at the meeting of the Royal Horticultural Society on August 13, it created quite a sensation, and received the high

award of a first-class certificate, a very exceptional mark of honour for a florist's flower. The individual flowers measure $4\frac{1}{2}$ inches in diameter, and are of a fine orange red tone, borne on branching spikes which promise a long succession of flowers. It was shown by that successful raiser of new Montbretias, Mr. G. D. Davison, The Gardens, Westwick, Norwich.

AN EARLY MICHAELMAS DAISY.

INDIVIDUALLY the flowers of *Aster acris* are not specially attractive, as they are so starry as to please comparatively few. Yet when seen on the plant in a mass they are valuable in the border, and one has even seen this Starwort employed in the exhibition stand with a distinct gain. Yet it is as a border or wild garden plant that it is best. Its defect is that it requires support, as it is almost hopeless to expect it to remain erect, unless in the most sheltered position, if unsupported by a stake. It forms such quantities of flower that the thin stems cannot support the weight of the inflorescence if there is much wind or rain. Unless the staking

is attended to timeously, the stems are twisted and a good plant of reasonable neatness becomes hopeless. If staked and tied in good time, it makes, however, a handsome plant, the small, neat foliage harmonising well with the starry purple flowers. There is a pink variety, and also a dwarfier-growing one called *A. acris nanus*, together with one called *A. a. draconuloide* with large, pale lilac flowers. I am far from saying that *A. acris* and its varieties rank among the *élite* of the Starworts, but their early-flowering habit is acceptable to many, and one would be unwilling to lack their flowers in August. S. A.

PLANTING HARDY FLOWERS.

WHAT are hardy flowers? They are plants with flower-stems which die down to the ground yearly, but, having rootstocks, remaining alive during the winter. Therefore they come under the same category as hardy perennials. Most hardy flowers should be planted (with few exceptions) now and up to the middle of November. Such things as *Pyrethrum*, *Tritomas* and *Scabiosa caucasica* are best left over until the end of March or the beginning of April. If one wishes to be successful in growing hardy plants, the border or bed must be properly prepared. This is the first step in the right direction. There are so many different varieties and species of hardy flowers that it would be impossible in these columns to write of the requirements of all, so I write broadly of what will answer the purpose for most of them. The ground

should be thoroughly well trenched or dug two or three spades deep, so as to loosen the soil, care being taken to get the best soil at the top. During the trenching or digging well-decayed stable manure should be added, spreading it well about in the trench, as this offers a good opportunity of getting it well mixed with the soil. J. L. E.

COLOURED PLATE.

PLATE 1453

THREE GOOD GLADIOLI.

DURING recent years few flowers have undergone such vast improvements as the Gladiolus, and the modern forms now rightly claim a place in the very forefront of our hardy border plants. Their simple cultivation, stately bearing and beautiful colours endear them to all, and they add a touch of brightness to our gardens at this season when it is most needed. The improvements that have been effected have not been in one direction only; the entire plant has been changed, in most directions for the better. By careful hybridisation such firms as Messrs. Kelway and Son of Langport have given us plants of greater vigour, larger flowers, and such a wide range of colours as our forefathers would have thought impossible. The accompanying coloured plate has been prepared from flowers kindly supplied by Messrs. Kelway, and represents three of their newer varieties. When the tops of Gladioli have been blackened by frost, the plants should be lifted, with their leaves entire, and hung up in a cool, airy but frost-proof place to dry. When thoroughly dry, the tops and any other refuse may be removed and the corms stored in a cool but frost-proof place for the winter.

A NEW HYBRID FOR THE GREENHOUSE: HEMANTHUS ANDROMEDA. (See page 438.)

THE GREENHOUSE.

A HYBRID HÆMANTHUS.

ON page 437 we give an illustration of the new *Hæmanthus Andromeda*, which received an award of merit from the Royal Horticultural Society at a recent meeting. It is a showy variety of light orange scarlet colour, and was exhibited in grand form by Mr. Cory, St. Nicholas, Cardiff. The following observations regarding the origin of this novelty have been sent to us by Mr. C. G. van Tubergen, jun., of Zwaneburg, Haarlem: "Referring to your note on *Hæmanthus Andromeda*, may I inform you that this hybrid has been raised in my nursery by crossing *H. Katherinæ* with *H. magnificus*, the former being the seed-bearer. A hybrid of a somewhat similar character has lately been raised in Germany by crossing *H. Katherinæ* with *H. puniceus*. The latter hybrid, which goes under the name of *H. King Albert*, is, however, neither so free flowering nor so large flowered as *H. Andromeda*, probably owing to the fact that here a special variety of *H. Katherinæ* was selected as the seed-bearer, and also because *H. magnificus* is larger flowered and altogether a better plant than *H. puniceus*. By crossing *H. Katherinæ* again with *H. Andromeda* I obtained a still larger-flowered hybrid than *H. Andromeda*. This secondary hybrid I named *H. Flora*."

ZONAL PELARGONIUMS FOR FLOWERING IN WINTER.

If we take the size of the plant into consideration, I daresay we should find, if a census was taken, that more Zonal Pelargoniums were grown in pots in this country than any other kind of plant. It is a plant that may be had in flower all the year round, and when the right varieties are grown their freedom of flowering is very marked. No wonder, then, that amateurs generally favour such a valuable subject for the furnishing of their greenhouses and conservatories, as the display made is a brilliant one, and especially cheering during the dull days of winter.

The Small Plant.—The value of the small specimen cannot well be over-estimated, as directly a cutting is rooted it produces a truss of blossoms, and usually the truss is an exceptionally fine one, so the cultivator has not long to wait after the insertion of the cutting for the flowers to appear.

Inserting the Cuttings.—About the end of August cultivators who wish to have some nice flowering plants in the depth of winter and in spring should insert cuttings. The latter are usually quite plentiful at this time, but after a

sunless and cool summer, such as we have experienced, the stems will be very sappy, and much care is necessary in dealing with them, else there will be loss through damping. The best compost is one of fibrous loam and leaf-soil in equal proportions, with sufficient sand to make all porous, this sand being added when the compost is first mixed. More sand must be placed on the surface of the soil in the pots just before the cuttings are put in. Some cultivators make use of the ordinary garden loam, but this turns sour, is fibreless and quite unsuitable. Manure must not be mixed with the compost, but some well-rotted manure may be placed in the bottom of each pot on the

soil firm around each cutting, give a thorough watering, and then place the pots in a warm frame or on a shelf in a greenhouse and admit plenty of air, but do not overwater. As soon as the cuttings are well rooted, repot them in 3-inch or 4½-inch pots and still retain them on warm, dry shelves. Much feeding must not be done before the first week in February, as it would induce a sappy growth at the expense of flowers.

Double-flowered Varieties.—King of Denmark, rose salmon; Improved Raspail, deep orange; Hermine, pure white; Gloire de France, salmon and white; Dagata, rosy mauve; Fascinator, orange, salmon and white; and Golden Glory, orange.

Single-flowered Varieties.—Phyllis, cerise; Lady Folkestone, blush pink; Barbara Hope, salmon pink; Mrs. Ewing, pale salmon; Mary Beton, white; The Sirdar, scarlet; and Paris, white and pink. Avon.

FLOWERS FOR GREENHOUSE BASKETS—SCHIZANTHUSES.

THESE are lovely plants for greenhouses and conservatories, and amateur cultivators who wish to have a nice display of blossom in the spring and early summer days cannot afford to be without a batch of plants. The strains now on the market are much superior to those one met with even a dozen years ago. There are hundreds of glass structures in town and suburban gardens which are only just sufficiently heated to keep out frost, and the owners often experience some difficulty in selecting plants which will survive the occasional low temperatures which must prevail. Schizanthuses are really not difficult plants to grow, and they will thrive in the average greenhouse. Seeds should be sown now either in pots or pans, and the resultant seedlings duly transplanted into the smallest pots.

In the first case it is necessary to disturb the roots of the seedlings and pot them separately. When one or two seeds are sown in a tiny pot, if more than one plant appears, all except one must be removed at a very early stage. The single specimen should be repotted, first, in a 3-inch pot, then in a 3½-inch pot, afterwards in a 5-inch pot, and finally, in a 6½-inch or 7½-inch pot. Usually, however, the single plants are flowered in 6½-inch pots. Give the young plants cool-frame treatment until the middle of September, then place them on a very sunny shelf in a greenhouse, leaving them there until the end of February. From that date until the flowering stage a position on a front bench in a greenhouse is the best for the plants.

Loam, leaf-soil and sand should be used for raising the seedlings in; manure is not necessary nor desirable. At the first and subsequent repottings a small quantity of well-rotted manure may be added to the compost, also some old mortar rubble. The variety *wisetonensis* should be pinched to

A SPRAY OF *CISTUS CYPRIUS*, A LITTLE-KNOWN ROCK ROSE OF HYBRID ORIGIN.

drainage material. Fill the pots as follows: First put in a hollow potsherd, then several smaller pieces. On the latter place a small portion of fibrous turf or several half-decayed leaves, and then the rotted manure, filling up each pot with the mixed compost and making it moderately firm. Use 3-inch pots for the cuttings, inserting one only in each pot; then, in due course, the rooted cutting can be repotted. Select cuttings with short joints and leaves of medium size, not those with sappy stems and large, succulent leaves. Remove the lower leaf and all the prominent scales from the stems, as these if left on will decay and result in the decay of the stem itself. Make the

cause a branching habit. Two pinchings will be enough; the flowers will then be large ones. Too much stopping weakens the shoots, and the latter then bear smaller flowers. Judicious feeding is very beneficial when the plants have well filled their pots with roots after the final potting. A beginner should grow the variety *wisetonensis* first, then add other varieties, such as *S. retusus* and *S. Grahami*.
SHAMROCK.

TREES AND SHRUBS.

ROCK ROSES.

THE Gum Cistuses, or Rock Roses, are a showy family of evergreen shrubs, and so easily grown that at least one or two should find a place in the warm corner of the smallest garden. The delicate nature and attractive colour

of the flowers, in particular those with large glistening white blooms, prettily spotted with dark crimson, make a gay show during the summer. In open positions, except in mild localities, most of the species benefit by protection in winter, as, being natives of South Europe, they are only sufficiently hardy to stand mild winters. The covering provided may be Bracken, Yew or Spruce branches. The best position for the more tender Rock Roses is at the foot of a warm south or south-west wall. Light loam, well drained, is the most suitable soil, as the roots are impatient of excessive moisture in winter. Seeds, cuttings and layering form ready means of increase. Sow the seeds in spring in a cold frame or slightly-heated greenhouse, using light, very sandy soil; prick off in boxes or pans, and later pot off each plant singly. Keep the young plants in pots in the frame the first winter and plant out in spring. August is a good time to insert *Cistus* cuttings in a cold or slightly-heated frame. Layering may be done in spring or summer.

A glance at the illustration is sufficient evidence of the free-flowering qualities of *Cistus Loretii*, a hybrid between *C. ladaniferus* and *C. monspeliensis*. The plants last in this condition for some weeks, for though the individual flowers are very fleeting, others open in rapid succession. *C. Loretii* is also distinctly valuable, as the flowers remain open in the afternoon much later than those of most of the species. The flowers are white, with the familiar five dark blotches. It forms a nice shapely bush 3 feet or more in height. *C. cyprus* (see illustration on page 438), is also a hybrid, 5 feet to 6 feet or more in height, the result of crossing *C. laurifolius* and *C. ladaniferus*. This plant is, unfortunately, figured in the *Botanical Magazine*, t. 112, as *C. ladaniferus*, a species from which it is markedly distinct, the most important being that while the flowers of *C. ladaniferus* are solitary, those of *C. cyprus* are in clusters of three or more. *C. ladaniferus* is also not so hardy. Both have the white spotted flowers. *C. albidus* is one of the most familiar purple-flowered species. The name, which to some may appear strange for

a plant with purple blossoms, refers to the leaves, which are clothed with a dense white tomentum.

The hardiest species of the genus is *C. laurifolius*, which is a vigorous grower, reaching a height of 6 feet or more. The large green leaves and pure white flowers, combined with the previously mentioned qualities, make this one of the most desirable and useful Rock Roses.

THE KITCHEN GARDEN.

TWO TROUBLESOME TOMATO DISEASES.

EVERY summer season brings to Tomato-growers at least two diseases and numerous specimens of them to the Editor. Both can, partly by cultivation, partly by spraying, be avoided to a large extent.

it is apt to be ric, for then the ideal conditions for the germination of the spores are present, yet I have met with growers who pride themselves on the fact that "we never ventilate," and their houses have not belied them. A too rich soil, encouraging rank growth, also lays the plants more open to attack. The maintenance of a fairly dry, buoyant atmosphere is a great aid to keeping the pest at bay.

Black Spot of Fruit.—The second trouble which is so common is the disease known as black spot. The fruit is attacked by a fungus called *Macrosporium solani*, and a black patch, somewhat depressed below the general level of the skin of the fruit, is produced. This patch is often at the "eye" end of the fruit, but not always only there. The spores are produced after a time, and may be carried to other fruits, on the feet of insects and in other ways. The important point is that the fungus can gain entrance, at

THE FREE-FLOWERING ROCK ROSE, *CISTUS LORETTII*.

Leaf Spot.—The first is the Tomato leaf spot, due to the fungus *Cladosporium fulvum*. Large yellowish spots appear on the leaf, and the thick felt of fruiting fungus branches of a brownish colour on the under surface of the spots. The spores from these branches are scattered by the wind, spraying, picking, insects and so on, and each is able to start a new centre of infection if the conditions are suitable. They are so minute that they may be present through the winter in any crevice in the house, on any piece of refuse Tomato plant and so on, and quite without their presence being known.

The disease is known almost wherever Tomatoes are cultivated under glass, but I have never seen it in the open air. Growers who ventilate their houses whenever possible are rarely troubled to any serious extent by this disease; but where a close, somewhat moist atmosphere is maintained,

least most readily, perhaps only into the fruit through cracks in the skin, so that the grower's aim must be to keep the fruit from cracking as far as he possibly can. The disease occurs both indoors and out. Fresh manure used in the compost seems to encourage the growth and attack of this fungus, and it should be strenuously avoided. A sufficient supply of potash aids in keeping the skin from cracking, and it may be applied now and then in the form of a solution of sulphate of potash in water at the rate of about half an ounce to the gallon. An irregular water supply also conduces to cracking, as may be readily seen in Tomatoes grown outdoors. Spraying, together with the removal of diseased parts, is also an important preventive means, and the best spray to use is undoubtedly home-made Bordeaux mixture such as is used in spraying Potatoes, provided always the materials are pure. SCIENTIST.

LETTUCE DUKE OF CORNWALL.

FREQUENTLY in the culture of vegetables or salads some few varieties stand out with greater prominence than others, and when well known become standard varieties owing to their general excellence. The above Lettuce comes under this category, as it has this year and last summer, during a period of great heat and drought, proved of great value, being of splendid quality and remarkably tender. Duke of Cornwall hails from the West of England, as its name implies, and has received an award of merit from the Royal Horticultural Society for its excellence. From seed sent by Messrs. R. Veitch, Exeter, at the trials of the National Vegetable Society the above was most noticeable for its perfect growth and crispness in a season when Lettuce was somewhat poor. There is no variety that I have grown which remains sound for a longer time when fully grown, and this is a great advantage. In addition, it is large, with a firm heart, and the outer leaves are much crested, in this way somewhat resembling Endive. Grown in good land, the plants often weigh as much as 3lb. or 4lb. and, having a flattish growth of the Drumhead type, with large, compact hearts, there is no waste, thus making it more valuable. Without doubt this is one of the best summer Lettuces we have of the Cabbage variety. W.

THE FRUIT GARDEN.

THE PACKING OF APPLES AND PEARS FOR MARKET.

THE growing of fruit for market has in the last fifteen years undergone a great development. The market-grower of thirty years ago was, with a few notable exceptions, a farmer who devoted some part of his land to fruit culture, and the fruit was grown on standards in grassland in the majority of cases. The increasing tendency towards specialisation has not left the fruit-grower untouched, and now all the leading men are devoting a large portion, if not the whole, of their land to fruit alone.

CALIFORNIAN APPLES PACKED FOR THE ENGLISH MARKET.

This development has had many important influences, and perhaps the greatest has been the abandonment of standard trees for bush trees or half-standards, and their culture on arable land. These modern growers were soon convinced that the most important factor for success was the selection of a variety suited to their soil and of high cropping powers, coupled with a firm flesh, which would enable the fruits to be marketed in good condition, and production of a sufficient quantity to supply the market for some considerable time. This led to a stringent selection, and the result is that in place of the dozens of sorts which formerly were marketed, most growers are now content with some half-dozen or less.

The next consideration was how to get the fruits to the consuming centres with a maximum of expedition and a minimum of damage. The bushel basket has many disadvantages which are obvious, and the alternative, the copying of the boxes of our Colonial and American competitors, was considered, and has now been adopted by very many of the larger growers. Perhaps the principal advantage of this method of packing is that it enables the producer to establish a brand, or trade-mark, thus obviating the disheartening practice which formerly lumped the good and bad together, and so lowered the price of the best to an average below its real merits. The box has, in the opinion of the writer, too many advantages to allow such small discouragements as will always fall to the lot of an innovation to check its adoption. It is evident, however, from the interesting show held at Ashford last year, when all fruit was exhibited in boxes, that some considerable practice and skill is needed for such efficient packing as we see in the case of Canadian and other foreign Apples. Various systems of laying the fruit in the boxes have been proposed, and these will vary according to the shape and size of the fruit.

The accompanying illustration of Apples shows what is called the "three two" pack, which is generally used for medium-sized fruit. The layer below will be laid on the same system, except that the "two" will come over the "three," resting in the depressions between those below. When smaller fruits are used they are often placed in equal rows, and the largest often permit but two abreast. It is most important that a standard size box should be used, and a useful size is 20 inches long by 14 inches wide and 10 inches deep.

In packing, the box is started upside down; that is, the fruits are piled in from the bottom of the box—that is, on the lid of the finished box—this being placed, of course, upside down, where it is desired that the fruit shall be the right way up when the box is opened, as in the illustration. Great judgment is necessary in filling the box, so that the fruit shall bulge slightly above the box. This is necessary so that, when the lid is nailed on, it shall act as a spring and hold the fruit firmly enough to prevent it moving, but not so firmly as to bruise. The fixing of the lid requires a clamp or press, which is a table having two metal arms, which seize the lid and, when pressure is applied to a foot-lever, press it down so that it can be nailed on. The nails must only be driven in at each end of the box, or the virtue of the "spring" of the wood lid will naturally be lost. The only other necessary appliance is a broad table, on which a good amount of fruit can be spread to enable the packer to select fruit of suitable sizes.

The packing of Pears is, from the softer nature of the fruit, a still more delicate matter, and here I would suggest that for all the more tender varieties the necessary firm packing should be

THE CALIFORNIAN METHOD OF PACKING PEARS FOR COVENT GARDEN.

gained by filling the box less full and covering with wood-wool and compressing this when the lid is affixed, so that the actual contact of wood and fruit is avoided. The use of paper on choicer dessert fruits adds much to their appearance, and gives at the same time a chance for the grower to get his name or brand noticed. An attractive label on the outside of the box is, of course, a necessity, and when a reputation is once established, this should sell the fruit without the need of opening the box. It cannot, of course, be too much emphasised that strict uniformity of sample and grade is the essence of success, and such a practice as "topping" not only damages the perpetrator, but also the whole fruit industry.

Care in gathering and storing is only one degree less important. That it will be difficult to educate packers there is little doubt; but I cannot believe that this is impossible of accomplishment with patience in this country as well as in others. The future of the fruit industry in this country depends upon improvement in distribution perhaps more than in any other direction, and that the systems of box-packing will aid in this direction cannot be open to doubt. The greatest credit must be given to the authorities at Wye College, Kent, for the impetus they have given to this matter, and those interested should write and enclose 6d. for a most interesting pamphlet, in which the various systems are described and the fullest directions given.

But why should the box method of packing stop at Apples and Pears? Plums and Cherries in America are marketed and sent for enormous distances in boxes, the latter fruit being packed in small boxes holding about a pound. Plums, if gathered early enough, would travel quite safely if well packed in boxes holding a dozen pounds or so, such as we see the Gages in which are sent from France and Spain to this country in such large numbers. I hope some enterprising grower will experiment in this direction, as the glut of Plums in Kent and Worcester, coupled with the extravagant prices asked in towns distant from these counties, make it evident that a market often exists which difficulties of distribution only hinder from being supplied.

Maidstone.

A. E. BUNYARD,

GARDENING FOR BEGINNERS.

HOW TO RAISE AND GROW HOLLYHOCKS. ✓

ALMOST everyone is familiar with the Hollyhock, for it is suitable alike for the town and the country garden, while the border must be a very small one which cannot find a place for a group of three or four plants. The

Hollyhock is one of those good old-fashioned herbaceous subjects seldom missing from pictures of gardens of bygone days. Hollyhocks were at that time extensively propagated from cuttings, named varieties being popular. Present-day strains of seeds are so pure and reliable that seedlings are now largely depended on, for as a rule they are less susceptible to disease. The tall, stately habit of the Hollyhock is a valuable addition to any mixed flower or herbaceous border, particularly those of considerable size, while masses in shrubbery borders or single plants growing up among the shrubs add considerably to the beauty of the garden.

Both the single-flowered and double-flowered Hollyhocks may be readily raised from seeds, coming very true to colour, and, unlike the Carnation, if one sows seeds from double Hollyhocks the seedlings all come double, and seedlings from single Hollyhocks all have single flowers. Both double and single varieties are notable for their rich and varied colours. Seeds may be purchased in mixture or in the following colours separately: Double—white, cream or sulphur, yellow, flesh, pink, rose, red, crimson, orange yellow and rose pink; single—white, yellow, pink, rose, deep red and other colours.

How to Raise Seedlings.—The raising of seedling Hollyhocks presents no difficulties to the cultivator. Seeds may be sown thinly in the open ground in drills from April to June, in a cold frame or cool greenhouse in August and September, or in a heated greenhouse during January or February. Strictly speaking, the Hollyhock is a hardy perennial, the roots lasting from year to year in the ground, pushing up annual growths which flower in summer. So readily are they raised from seeds that it is quite easy to treat the Hollyhock as a biennial, or even as an annual by sowing the seeds in heat early in the year.

Treatment of Seedlings.—The April to June raised seedlings should be transplanted about nine inches apart when ready during the summer, moving them to their flowering quarters in March. Seedlings raised in frames in late summer and autumn may be pricked off in boxes when ready, keeping these in the frame during the winter, and potting off singly about February preparatory to

planting outside during April. The procedure for the January or February raised seedlings will be similar, except that when pricked off in boxes they should be kept in heat till growing freely, and they will not be ready to plant outside till May.

How to Grow the Plants.—Hollyhocks will grow in most soils, yet no plants yield better

carmine. Double—Black Knight, dark crimson; Eucharist, yellow; Flora, pink; Stephen Phillips, rich rose; White Lady; and Viscount Wolseley, rich red. Named varieties are propagated by cuttings in late summer or spring and by division of the clumps, March being a good time. Insert the cuttings in pots of light, sandy soil,

placing them in a cold or slightly-heated frame at the end of the summer or in a heated frame in March. Any difficulty experienced in keeping the named varieties during winter may be obviated by lifting the roots in late autumn and placing them in a frame for the winter.

The Hollyhock Disease.—The dreaded Hollyhock fungus (*Puccinia malvacearum*) may be kept in check by spraying with a solution of Condy's Fluid or permanganate of potash, and also with a mixture of soft soap and sulphur dissolved in water. Messrs. Webb and Brand, the well-known Hollyhock specialists, use the following mixture: Slake one peck of lime, and when cool add one peck of soot, 1 lb. of flowers of sulphur and half an ounce of sulphate of copper (finely powdered). Pass the mixture through a fine sieve and dust the plants well over with it three or four times during the growing season, preferably early in the day while the dew is still on the plants.

A GROUP OF HOLLYHOCKS. SEED MAY BE SOWN NOW IN COLD FRAMES.

results when planted in deeply-tilled and liberally-manured ground. A mulching of decayed manure is beneficial in May or June, and frequent waterings should be given during dry weather. By sowing seeds in April and September or early spring in heat, the season of flowering will extend from July until October. Three feet apart each way is a suitable distance to plant Hollyhocks. They grow from 8 feet to 12 feet high.

Good Named Varieties.—Would-be growers who have a fancy for named sorts are recommended the following: Single—Brooklands, white; Corona, yellow; Pom-pom, dark maroon; Rosy Morn, pale rose; Brodrick, rich red; and Penzance,

new shoots are freely made; but they do not bear flowers. The latter are borne on the young shoots made during the previous year, and if a sufficient number of these be left, not only will they flower freely, but the blossoms will be very large and pure in colour. The result will be, year after year, wreaths of the Mock Orange blossom. Furthermore, the plants will increase in vigour and their form be improved. Some of the older wood should be cut out and, if overcrowded, a few of the younger branches, too; then the remaining ones will mature and yield a plentiful crop of blossom the following year.

SHAMROCK.

PRUNING THE MOCK ORANGE.

THE flowers of this plant are very lovely during the latter part of May, throughout June and the early part of July. In some gardens, however, one sees very fine hushes which do not blossom freely, and this flowerless condition is chiefly owing to the wrong way in which the pruning is done. Old specimens, left unpruned from year to year, rarely fail to bear flowers, although the latter are small. If the young wood is cut back injudiciously, new shoots are freely made; but they do not bear flowers. The latter are borne on the young shoots made during the previous year, and if a sufficient number of these be left, not only will they flower freely, but the blossoms will be very large and pure in colour. The result will be, year after year, wreaths of the Mock Orange blossom. Furthermore, the plants will increase in vigour and their form be improved. Some of the older wood should be cut out and, if overcrowded, a few of the younger branches, too; then the remaining ones will mature and yield a plentiful crop of blossom the following year.

GARDENING OF THE WEEK.

FOR SOUTHERN GARDENS.

The Flower Garden.

Lawns.—The grass will not need cutting so frequently now as it did in the earlier part of the season, but once a week at least the machine should be run over to remove the straggling growths and so improve the appearance. During damp weather rolling occasionally will be of great benefit, and especially to lawns or turf that were newly laid this spring. Now that it has become thoroughly settled, the edges may be cut into proper shape with the edging-iron. This work requires to be carefully done, and, where possible, should always be carried out to a line.

Bedding Plants.—Propagation during the next week or two will be in full swing, and many are the plants nowadays brought into the scheme of summer bedding. With some of the plants the full stock must be propagated at once, whereas with others it is sufficient to root a quantity for stock purposes and propagate again from them in the spring. The latter include *Iresine*, *Alternanthera*, *Mesembryanthemum*, *Ageratum*, *Cuphea* and variegated *Nasturtium*.

Lantanas are most effective, and standard plants take a considerable time to grow, but useful bushy plants can be rooted and grown on in the New Year from cuttings obtained from a few stock plants, which should be potted up and stood in a shady and sheltered place when the bedding is over, well watered in and wintered in a cool house.

Swainsona galegifolia alba is an attractive bedding subject, the white flowers being freely produced and harmonising well over almost any dark groundwork. A stock should be propagated at once by taking cuttings and rooting them in a warm house or pit with bottom-heat.

The Rock Garden.

Coroeka Cotonaster.—When the bulk of the flowering subjects are passed it is then that a careful selection of suitable shrubs, discriminately planted, proves a great attraction. This New Zealand subject is, to all purposes, practically hardy and exceptionally well adapted for planting on rockwork, being of slow growth. The branches are curiously intermingled, which, together with the small round foliage, makes it distinctly interesting.

Muehlenbeckia varians.—This is another shrubby subject eminently suited for trailing and generally associating with rockwork. It is of quick, rampant growth and well suited for covering barren places.

The Water Garden.

General Remarks.—Now that growth on the various subjects, both aquatic and semi-aquatic, is completed, before they die down and become dormant any alterations necessary to improve the appearance for next season should be noted. For instance, the more vigorous *Nymphaeas* will probably need restriction, and these, unless their position is marked, are difficult to find. Note what subjects succeed best by the water's edge, and plant more extensively if needs be. One of our showiest subjects for late summer was *Senecio Ledebourii*, throwing up large heads of yellow flowers on stout stems above bold and handsome foliage. If the Water Lilies become badly infested with aphids, as they sometimes do, spray with a good insecticide when the flowers are closed.

Plants Under Glass.

Malmaison Carnations.—As soon as the young plants are sufficiently rooted, sever the layers from the parent plants and very carefully lift with a hand-fork for potting up. For ordinary-sized plants 3-inch pots will suffice; but where a large number of roots have been formed, use slightly larger receptacles. Pot fairly firm and stand in a shallow frame facing south, and shade if necessary for a few days.

Calceolarias.—Continue to pot off into small pots the seedlings as they become large enough. As with many other subjects, do not discard the tiny ones, as oftentimes these are the best and eventually make not only the best plants, but possess the richest markings. Use an open compost and grow quite coolly. Stand the pots on inverted ones over a good bottom of cinder-ashes, so that slugs cannot reach the plants, and damp the surroundings often and shade from sunshine.

Cyclamen.—To obtain strong plants for flowering next autumn, seed-sowing must not be delayed. Whether the seed is sown and raised in heat, or allowed to germinate more slowly on a shelf in a cool structure, is a matter of opinion. Sow the seeds thinly in spare pans or boxes, so that there is no need to disturb them immediately they are germinated. Avoid an over-depth of soil and use plenty of drainage; then the compost will remain for some time in a sweet condition. Keep the plants due to flower this winter growing by the use of occasional stimulants and the free use of the syringe in warm weather, especially keeping them shaded from bright sun and their surroundings moist. As the flower-buds show colour above the foliage, remove them by pulling them clean out from the base.

The Hardy Fruit Garden.

The Fruit-Room.—Whatever this may be, the interior should be thoroughly cleaned out without delay and got in readiness for storing the fruit.

Gathering of Fruit.—This requires carefully attending to, and especially with Apples that are to be kept for some months. With the earlier-maturing varieties that refuse to keep satisfactorily it is not so important. When to gather is another question frequently asked, and this also has a great bearing on their keeping properties. With late keepers allow the fruits to hang as long as possible, unless, of course, they drop badly, when picking should be carried out, and even then many will be found to part badly from the trees; but do not be tempted by the first few to fall. Handle carefully and do not place too many in bulk. If possible, finally store in a single layer and on a base where the air can permeate through, and label the varieties accordingly.

Pears require especially careful handling, and should certainly not be placed any thicker than one layer, so that as they ripen they may be selected for consumption. Frequently examine these, otherwise many will over-ripen.

The Kitchen Garden.

Spring Cabbage.—The earliest plants of the first sowing should be planted out as soon as ready. It is a good crop to follow the Onions. Well dig the ground, working in any farmyard manure. Make firm and plant in rows 18 inches apart and 1 foot between the plants, so that in early spring the alternate ones can be removed for filling gaps, which often occur after a wet winter.

E. BECKETT, V.M.H.

Aldenham House Gardens, Elstree, Herts.

FOR NORTHERN GARDENS.

The Flower Garden.

Lobelia for Stock.—Plants that have been doing duty in the greenhouse, as well as surplus ones in pots, must not be permitted to flower any longer, else they may damp off during winter. If there is none in pots, then delay no longer in taking rooted slips off old plants; but as a rule these cannot be depended on to winter safely.

Roses.—The first crop of flowers passed off very quickly, but now the beds are again well furnished, and there is a great display of the late-blooming climbers. Mildew has been apparent owing to the very wet weather, especially where the beds are confined. Any weak or decaying wood should be cut clean out if it has not been done already. It helps *Aimée Vibert* considerably to shorten the bloomed-out shoots, the late crop of blooms soon covering the plants again.

Making Up Blanks.—*Chrysanthemums* and *China Asters* will be found of much value now and later to fill up blanks made by earlier-flowering plants. These and many other plants transplant successfully with very little care. I invariably find that men attempt to lift too much material with each plant, which causes the ball of soil to split. No more soil than will attach itself to the plant should therefore be lifted. The ground should be well stirred previous to planting, the plants set deep into the ground, and the soil immediately saturated with water and kept saturated for a few days till new roots have protruded. *African Marigolds* should not be lifted till they are in flower, when the singles can be kept from the doubles, each being massed by itself.

Lilium candidum.—This is the time most suitable to lift and replant this Lily. It is a very

accommodating plant, which I have lifted in full growth without its exhibiting any signs of resentment. Like the *Hollyhock*, the disease is less obvious in some parts of the garden than in others. In a shaded part I have never seen the disease, and the flowers there succeed the earlier-flowering ones which are exposed.

Violets.—Plants which are yellow in the foliage will soon recover on being surface-dressed with a stimulating manure, pigeon-manure, soot, superphosphate, or a good proprietary composition being suitable for the purpose. Doubles, as a rule, do not show these symptoms of distress, but they also should be manured.

Indoor Fruits.

Strawberries.—It is full time for the potting of these. A strong yellow loam with a sixth part of desiccated cow-manure reduced to powdery fineness suits them best. A difficulty with the inexperienced in potting is that the plants are either put too low or too high in the pots, just level with the string of the runner being right. Hard potting is essential. After a few days, especially if the weather is hot, frequent waterings will be necessary.

Black Grapes.—To colour these properly they must have time; consequently a high temperature, especially at night, should not be attempted. Water at the root in sufficient quantity is another essential, and that slightly manorial is to be preferred to the pure liquid. It is not necessary to have much ventilation, generally a little—a few inches at most of the top ventilator open—being enough to ensure the health of the Vines. *Black Hamburgh*, as a rule, will be ripened, and to keep the colour a shading may be sprayed over the glass and the inside of the viney kept cool and dry. Dry straw spread neatly over the borders is a means to this end and saves the borders from drying, and in this way is a help to proper conditions.

Pot Peaches.—As the crop is gathered off each tree it may be taken out of doors, not crushing the trees together, but giving them plenty of room. Nor must they be neglected in the way of manure-water, the flower-buds for another year depending on the manner in which the trees are treated in the autumn. Rub off all superfluous growths and keep the foliage clean by regular washings with pure water.

Indoor Plants.

Pelargoniums.—Plants for autumn blooming should be transferred to a well-ventilated and light structure, in which the flowers will open in greater purity than out of doors. Slight applications of sulphate of ammonia and superphosphate give an added brilliance to the colours; but the plants, it must be remembered, are easily damaged if over-manured.

Calceolaria Burbidgei.—If plants of this *Calceolaria* are too pot-bound to flower sufficiently, they ought to be shifted into larger pots at once. Manurial feeding, which can be resorted to with many other plants, has little effect on this if the rooting space is contracted. As soon as the shoots begin to extend for bloom they must be staked efficiently.

Tuberoses.—Those potted late and which have been growing in a cool structure will soon begin to flower, and it will be necessary shortly to give them a higher temperature in order that the flowers may expand nicely. The plants will also need much more water at the root and a very short stick to each spike. It is often annoying to find a finished spike tied all its length, and needlessly, to a long stake.

Annuals.—Another sowing of *Schizanthus* may be made soon in 3-inch pots, as advised for the first batch; also of varieties of *Clarkia elegans* to flower in late spring. *Mignonette* should also be sown without further delay. This does well sown in 6-inch pots, thinning out the seedlings to the right number. A light, very rich compost suits them well, and they must never be allowed to suffer a check to growth.

Smilax.—Late-started material for Christmas and spring should be stringed before the growths get entangled. Linon thread is the best material to use, being strong for its thickness, and it does not readily break when drawing it from the cut sprays. Aphids occasionally attacks the plants, which may be syringed with a *Quassia* solution or else tinned.

R. P. BROTHERSTON.

Fyninghame, Prestonkirk, N.B.

DAFFODIL NOTES.

SOME MODERATE-PRICED DAFFODILS FOR SHOWING.

(Continued from page 431.)

Division III.a, Small Cups with Yellow Perianths.—It is surprising how comparatively few good flowers there are in this section with yellow perianths, when we consider the very large number of those with white. I think the word "whitish" in the Royal Horticultural Society's definition is partly responsible. "Whitish perianth" is there taken to cover such a flower as Firebrand, and this cuts out so many from the yellows that there are but an insignificant number left. In one catalogue in which I counted up the number of varieties listed under III. (Small Cups), I found seventy-two, and of these only thirteen were marked "a," that is, as having a yellow perianth. The famous old Barrii conspicuus is the best known by far, and even now is often seen at shows, not because there is nothing else, but because it can still hold its own. Castle and Occident are indispensable. The former has a very distinct and pleasing shade of a sort of coffee red in the cup, with good, smooth-pointed, pale yellow segments; whereas the latter is a rounder flower with a great deal of red in the crown. Unfortunately, as it is very late to flower, it is uncertain whether Northern growers will have it in bloom by the time it is wanted. Stonechat, Blood Orange, Fusilier, Yellow Poet, Glitter, Joan of Arc and Concord are other names that come to me as I write. The last is a very perfect show flower, and should be in every collection. The flat yellow crown with its narrow deep red edge is telling. Some day Furnace and Jasper will come under the description of moderate-priced flowers. They have the reddest cups of all Daffodils, and on this account are highly prized and priced. At least, ten guineas and fifteen guineas is getting on that way.

Division III.b, Small Cups with White Perianths.—I was going to say it is difficult to get a flower that is not in "III.b." It would be a pardonable exaggeration. Corresponding to this wealth of choice we find quite low-priced varieties will enable anyone to put up a collection of a high standard of excellence. Take these twelve: Cirlet, Incognita, Ethelbert, Cresset, Armored, Branston, Southern Star, Sunrise, Red Chief, Fair Maiden, Egret and Eyebright. Sunrise is priced about half-a-guinea, but I think none of the others is over six shillings. They are a magnificent lot, and, if they are well grown and tastefully staged, would not have to hide their heads and think they were Cinderellas even beside such proud beauties as White Star, Cossack and Challenger. In the baker's dozen just mentioned we have four famous varieties: Incognita, with its eye of pale warm brick red and long white almond-shaped segments, comes near to the charmed circle of "great flowers." If everywhere was Lissadell, I think if it knocked for admission it would be admitted; but, alas! I cannot grow it to get such colour as they do over against the Atlantic; neither, I fear, can one reader in fifty. Ethelbert, which so charmed this year's chairman of the National Sweet Pea Society's committee, is an exquisite bloom, and the gentle up-and-down of its perianth is always greatly admired. We want more of this Almira-looking type. They are a welcome change from the perfectly flat petalled ones. Sunrise has a shallow orange yellow cup, with conspicuous rays of yellow running up each petal. It is highly effective on a stand and most distinct. Southern Star is after the

style of the old Crown Prince. It has a well-defined band of red round the edge of the cup, and long, rather pointed perianth segments. As Cossack now comes within my definition of moderate priced, I must call especial attention to it. It is superb for showing and quite the equal of more highly-priced all-red flat cups, and as I have grown it for three years I can testify to its being a good doer. A cheaper variety, with an all-red centre, may be had in Scarlet Eye. It is a very bright and pleasing flower, not so round as Cossack, nor has it such a deep-toned eye. With the mention of Red Beacon, which I remember so well at the great Haarlem Bicentennial, my list must close. It has a similar cup to the last two, and in quality and price comes about halfway between them.

Division IV., Leedsii Daffodils.—Although I see the appropriateness of such an omnibus section, I believe there is a sort of secret danger ahead if schedule-makers and judges do not recognise its *comprehensive* character. As the incomparabilis and Barri divisions have their white and yellow perianths to enable them to be split up, so I think the Leedsii might be divided into star-shaped and round. Nothing about any dividing up is said in the Royal Horticultural Society's definition; but that could easily be got over by a note in the requirements for this class to say that the judges will take into consideration in giving their awards the diversity of form among the blooms staged. Much as I love those beautiful white flowers like White Queen, Mrs. W. O. Wolsley, Venus and Empire, I would not like to see things like Countess of Southesk, White Slave, Ariadne and Bianca pushed on one side. They are so charming that it would be a Leedsii disaster indeed were they to be allowed to drop out of our shows. At present they *have to come in* simply because a dozen of such varieties as Empire, Hon. Mrs. Francklin, Elfrida Pearson, Mrs. W. O. Wolsley, Lord Kitchener, Czarina, Patrician, H. C. Bowles, Swashbuckler, Sirdar, White King and Lowdham Beauty are out of the question to all but millionaires. To show three flowers of each of a twelve like these would mean an outlay of something like £250 to £300. After all this, let me now select my dozen moderates. I know before I start the task will be difficult, not because I cannot find enough beautiful varieties to fill my requirements, but because I must leave out others almost equally lovely to my eyes, and perhaps more so to others. Here, then, is my selection: Moonbeam, White Queen, Countess of Southesk, Venus, Ariadne, Eoster, Bianca, Hoar Frost, Evangeline, Penguin, Queen of the North and Thora. If I omitted the perfect Moonbeam on account of its lateness, my choice would lie between Diana and Lucia. Most of these are known to my readers. Hoar Frost lives at Lismore, "a lovely flower when fully expanded; perianth and cup of pure white, the latter beautifully margined with a fine line of pink." Countess of Southesk—my Leedsii Frank Miles at Cork; Queen of the North shone forth once at least this spring from Messrs. Barr's usual stand just inside the door on the left-hand side of the Royal Horticultural Society's Hall; Thora, the lovely brunette, has been enticed to Bletchley. So now you know where the *rariores aves* of my "little crowd" are to be found.

Division V., Triandrus Hybrids.—In my humble opinion the prices asked are absurd. One consolation is they will probably soon get lower, for calathinus is a very potent pollen parent, and there is no reason why everyone should not raise his own. Most Daffodils will seed to calathinus. The loveliest are the pure white teacup-shaped ones which come

from such a cross as Minnie Hume and calathinus. To show what I mean about prices, I find in one list seventeen varieties. Of these only four are under a pound. Richard Strauss, Queen of Spain, Dorothy Kingsmill, Bennett-Poë and White Witch seem the only possible ones for shallow pockets.

Divisions VI. and VII., Cyclamineus and Jonquil Hybrids.—Cyclamineus hybrids may be omitted; so, too, may Jonquil hybrids, although I feel sure in time we will have this section much better filled up. Buttercup is the pioneer of this new race of rich deep Guernsey hutter yellow selfs. It is a very beautiful flower, and is bound to be a great popular favourite in the course of time.

Division VIII., Tazetta and Tazetta Hybrids.—From a show point the best are Elvira, Jaune à Merveille, Orient, Irene and Sunset. If a sixth is wanted, I would suggest Triumph or Aspasia. Jaune à Merveille has about five or six flowers of a pretty shade of soft yellow, with an orange yellow cup, often shaded with apricot. Orient has a pure white undulating perianth of much substance, with a pale yellow eye, with a very distinct thin red edge. Of the Polyanthus Narcissi, the best are Bazelman major, Mont Cenis, Maestro and Newton, but for practical show purposes they may all be neglected.

JOSEPH JACOB.

(To be continued.)

FUNERAL OF THE LATE ALEXANDER DEAN, V.M.H.

AMID many tokens of deep respect, the remains of the late Alexander Dean, whose death we announced in our last issue, were laid to rest in Kingston-on-Thames Cemetery on Monday last. Although the afternoon was exceedingly wet, there were a large number of the deceased's relatives and friends present. The Committal Service, which had been prepared by the deceased, was read by Mr. Philip Thomas of the Church of Humanity, Holborn, a sect of which Mr. Dean was a prominent member. In addition to his relatives, the following were among those present at the graveside:

Messrs. J. Cheal, representing the Royal Horticultural Society; the Mayor and ex-Mayor of Kingston; Messrs. Owen Thomas, V.M.H., W. Poupart, Brian Wynne, Horace J. Wright, F. W. Harvey, Editor of THE GARDEN; W. Tinley of the *Gardeners' Chronicle*, J. Naylor of *Gardening Illustrated*, E. H. Jenkins, W. Bates, E. G. Quick, hon. secretary of the National Vegetable Society; W. J. James, W. Hayward, W. G. Smith (Kingston), A. E. Burgess, Horticultural Instructor to the Surrey County Council; John Crook and T. Gibbons, Esber Court Gardens. Many members of the Kingston branch of the Humanitarian Society, which was founded by the deceased, were also present. The floral tributes were exceedingly beautiful and numerous, and included, in addition to those from his widow and other relatives, tributes from the members of the National Vegetable Society, of whose committee the deceased was chairman; the Kingston Liberal Association, Kingston Adult Schools, Kingston tradesmen, the Kingston Saturday Popular Entertainments Committee, Mr. G. C. Parnaby, J.P., Mr. E. H. Jenkins, the Editor of THE GARDEN, the *Surrey Comet*, Mr. and Mrs. Ryan, Mr. and Mrs. Hayward, and Mr. and Mrs. J. J. Shakespere.

SOCIETIES.

SHREWSBURY SHOW.

FAVOURLED with good weather on the opening day, the great Shrewsbury Show was held on August 21 and 22. It was a magnificent exhibition; indeed, by a general consensus of opinion it was one of the finest in the annals of the history of the Shropshire Horticultural Society. The magnitude and all-round excellence of the produce shown place this far-famed exhibition in the premier position among provincial shows. The show was again held in the beautiful grounds known as the Quarry. Competition generally was very keen. As usual, Grapes proved to be one of the strongest features, and the best growers in the country were brought into competition. The champion prize for the decorated fruit-table was won by the Duke of Portland, whose gardener, Mr. Gibson, succeeded in defeating the redoubtable Mr. Goodacre by a very narrow margin. Roses were far better than might have been expected, and the Silver Challenge Rose Bowl, presented by the president of the society, W. W. G. Philipps, Esq., brought out one of the finest competitions that have ever been witnessed.

FRUIT.

The keenest interest is always centred around the class for decorated fruit-tables. This is one of the features of this great show. There were only three entries on this occasion, but the tables were of the very highest order. The class is for thirty dishes, and the first three prizes are £25, £20 and £17 10s. Grapes, Apples, Melons, Peaches, Nectarines, Pears and Plums were to be seen in the height of perfection on the three tables in competition. There was very little between the merits of the first two competitors. The first prize was won by the Duke of Portland, K.G., Wolbeck (gardener, Mr. Gibson), who scored a fine total of 253½ points. With only one point between them, the second prize went to the Earl of Harrington,

shown, all of which had been grown at the Wisley Gardens, Surrey. Large gold medal.

Messrs. Thomas Rivers and Son, Sawbridgeworth, quite excelled themselves with an excellent collection of pot fruit trees. The collection included many Nectarines and Peaches, Plums, Apples, Pears, Grapes, Oranges and Figs. The arrangement was perfect and the quality of the very highest. Large gold medal.

The King's Acre Nurseries, Limited, Hereford, staged an excellent collection of pot fruit trees, including Apples, Pears, Plums, Figs and Grapes. For quality of fruit this collection was deserving of the very highest praise. The following Apples were remarkably good: Collini, Cox's Pomona, Peasgood's Nonsuch, Allington Pippin and Emperor Alexander. Large gold medal.

The attractive fruits of the Strawberry-Raspberry were displayed by Mr. B. Bowdler, Shrewsbury.

The first prize for a collection of twelve dishes, in not less than nine kinds, was won by the Duke of Newcastle, Worksop (gardener, Mr. S. Barker). This collection contained fine fruits of Apple Ribston Pippin and Pear Triomphe de Vicence; second, Lord Biddulph, Ledbury Park (gardener, Mr. H. Cotton); third, Alderman Bewley, Rathgar (gardener, Mr. D. M. McIntosh).

VEGETABLES.

As in former seasons, this section was again quite a leading feature, the entries being even heavier than usual. The quality throughout was excellent. The whole of the seedmen's classes were well contested and brought excellent competition.

In Class 112, open to all, for a collection of twelve distinct kinds, which brought seven competitors, the Hon. Vicary Gibbs, Aldenham House, Elstree, was an easy first with a splendid collection, including Celery, Leeks, Onions, &c. Mr. J. Hudson of Leicester came second with a meritorious collection.

For a collection of nine kinds, distinct, Class 113, there were five competitors. The judges had a great difficulty in awarding the prizes, the collections in each case being

THE FIRST PRIZE TABLE OF FRUIT SHOWN BY THE DUKE OF PORTLAND AT SHREWSBURY.

Elvaston Castle (gardener, Mr. J. H. Goodacre), who had 252½ points to his credit. The third place was gained by Lady Henry Somerset, Eastnor Castle, with 235½ points.

For twelve bunches of Grapes there was strong competition, and the first prize of £20 was won by the Duke of Westminster, Eaton Hall (gardener, Mr. Barnes); the second prize was won by the Earl of Harrington. The finish of the Muscat Grapes in the first-prize collection was quite exceptional.

For four bunches of Grapes, two bunches of a black variety and two of a white variety, Mr. R. J. Corbett, Towyn (gardener, Mr. J. Jones), was first with two capital bunches of Gros Maroc and two equally good bunches of Muscat of Alexandria. Second, Captain Heywood Lonsdale, Shavington (gardener, Mr. J. Mills).

Mr. J. Brinton, Stourport (gardener, Mr. W. H. Wilson), was first for two bunches of Black Hamburg Grapes.

For eight Peaches, the Duke of Newcastle, Worksop (gardener, Mr. S. Barker), was first with a superb dish of Crimson Galande.

For a single bunch of Black Hamburg, Lady Henry Somerset, Eastnor Castle (gardener, Mr. G. Mullins), was a good first.

For two bunches of black Muscat varieties, G. E. Lonax, Esq., Hayton (gardener, Mr. E. Jones), was first with two capital bunches of Madresfield Court.

For two bunches of Madresfield Court Grapes, Colonel H. C. Legh, Knutsford (gardener, Mr. A. J. Cooke), was first with a pair of handsome bunches.

Some excellent Alicante Grapes were seen in the class for two bunches. First, Mr. J. W. Raynes, Old Colwyn (gardener, Mr. J. Barker).

In the class for two bunches of any Grape not given in the schedule, Lord Harlech, Brogyntyn (gardener, Mr. T. Lambert), was first with two heavy bunches of Alnwick Seedling.

Grapes are always a strong feature at Shrewsbury, and not the least interesting exhibit was that of a collection of known and little-known varieties from the Royal Horticultural Society. About two dozen varieties were

very close. F. Bibby, Esq., Hardwicke Grange, secured the first prize, and Captain H. Lonsdale, Shavington Hall, second.

Class 114, which was for six dishes of Potatoes, brought very good and keen competition, there being twelve competitors in this class. Colonel Cornwallis-West secured the first prize with a fine collection, including such varieties as King Edward, Goldfinder, Sensation, &c., with Lord North of Banbury a good second.

The whole of the single dish classes were well filled with some splendid examples. Unfortunately, owing to lack of space, we are unable to enumerate the winners.

Messrs. Barr and Sons, King Street, Covent Garden, displayed a magnificent collection of vegetables, comprising some eighty dishes, prominent among them being Brazilian Beet, Capsicums, Red Cabbage, Celery (pink and white), Barr's White Champion being exceptionally fine; Potatoes in many varieties, Onions, Timmy Golden Nugget, Beans, Peas, &c. The whole were exceptionally well staged. Silver-gilt medal.

The Hon. Vicary Gibbs, Aldenham House, Elstree (gardener, Mr. E. Beckett), also staged a beautiful collection, most artistically arranged, all, as usual, up to the high standard of perfection. It comprised about ninety dishes, including Lettuce, Butter Beans, Kohl Rabi, Radishes, New Zealand Spinach, Globe Artichokes and many other varieties. Large gold medal.

Messrs. Sutton and Sons quite excelled themselves in their highly attractive and well-arranged exhibit of vegetables, intermingled with bright colours of Asters, Antirrhinums, Begonias and various annuals. A capital selection of Melons was dispersed throughout the collection. Large gold medal.

Messrs. Webb, Wordsley, Stourbridge, had an exquisite collection of flowers, vegetables and Melons. The Onions, Carrots and Tomatoes were in the best of condition, and arches of Carnations and Sweet Peas gave a suitable setting to this admirable collection. Large gold medal.

Messrs. Dickson and Robinson, Manchester, staged a most glorious display of Lilliums, viz., *L. auratum*, *L.*

Melpomene and *L. longiflorum grandiflorum*, also Carnations in variety, with a superb collection of Peas, Melons and Tomatoes in the foreground. Gold medal.

The society's large gold medal was awarded to Messrs. Clibrans for a magnificent display of flowers, fruit and vegetables of the highest excellence.

HARDY PLANTS.

Herbaceous plants were well represented, although in some instances the flowers were unmistakably weather-beaten. Phloxes were not quite so good as we have seen them on previous occasions, but late-flowering Gladioli, Pentstemons and Gaillardias were all three worthy of special mention. With the exception of new Montbretias, there was a decided lack of outstanding novelties among herbaceous plants. There was splendid competition in Class 5 for a group of hardy and perennial plants with a background of Bamboos, &c., with a pool of water, Nymphaeas and other water plants. The premier place in this class fell to the lot of Messrs. Gunn and Sons, Olton, with a most beautiful show of hardy flowers, such as Hollyhocks, Phloxes, Spiraeas and Lilliums. In the foreground was a little water garden containing many flowers of Nymphaeas in a variety of colours. Second, Mr. J. E. Knight, Wolverhampton; third, Mr. T. R. Hayes, Keswick; fourth, Messrs. W. Artindale and Son, Sheffield. Mr. T. R. Hayes was first for a collection of rock and alpine plants with a very effective exhibit, occupying 100 square feet, arranged upon the ground. Mr. R. Hayes, Grasmere, and Messrs. W. Artindale and Son were the runners-up in this interesting class.

A raised water garden, surrounded by Delphiniums, Lilliums and a host of water-side plants, was erected by Mr. Amos Perry, Enfield, Middlesex. The arrangement left nothing to be desired, the colour combination and grouping being most pleasing. A large gold medal was awarded for this admirable group.

A gold medal was awarded to Messrs. Gunn and Sons, Olton, who put up an extensive group of Phloxes, including all the varieties that are worth growing.

Baker's, Wolverhampton, staged a most effective group of alpine and herbaceous flowers, for which a gold medal was awarded. Phloxes, Delphiniums, Senecio clyorum, Dahlias and early-flowering Chrysanthemums were alike equally well shown.

Messrs. Dicksons, Royal Nurseries, Chester, were represented by a grand collection of herbaceous plants, in which Gladioli and the lovely Californian Tree Poppy (*Romneya Coulteri*) figured prominently. A silver-gilt medal was awarded for this exhibit.

A similar award was made for Pentstemons, Phloxes and Antirrhinums shown by Mr. Forbes of Hawick, which aroused the admiration of all visitors. The little-known hardy plant, *Encemis punctata*, was included in this group.

Messrs. Isaac House and Son, Westbury-on-Trym, Bristol, had an interesting collection of hardy alpinics, in which Campanulas were most conspicuous. The same firm had a well-arranged group of herbaceous flowers. Phloxes were a feature in this group, for which the high award of a gold medal was given.

A wonderful display of Montbretias, including the latest creation, *Star of the East* (illustrated on page 437), was shown by Messrs. Wallace and Co., Colchester. A silver-gilt medal was awarded.

A gold medal was awarded to Messrs. Jarman and Co., Chard, for a comprehensive group comprising Pelargoniums, Roses, Dahlias and their speciality, the new Centaureas.

Mr. A. W. Thorpe, Lichfield, had a grand collection of early-flowering Chrysanthemums, for which a silver-gilt medal was deservedly given.

A similar award was made to Messrs. Pritchard and Sons, Shrewsbury, who staged alpinics, chiefly Campanulas, in pots and ornamental bowls, and Ferns.

Messrs. Harkness and Sons, Bedale, Yorks, sent a wonderful collection of Gaillardias in warm orange tones of colour. The variety Mrs. Mackellar is remarkable for its very large flowers.

Messrs. G. Gibson and Co., Leeming Bar, Bedale, Yorks, had a capital bank of herbaceous flowers and Roses. The magnificent scarlet *Lobelia Gloire de St. Amnes* was shown in this group.

Messrs. Caldwell and Sons, Knutsford, showed Phloxes and the general run of herbaceous plants in good form, but somewhat overcrowded.

Mr. Robert Hayes, Grasmere, showed a nice lot of Phloxes from Wordsworth's country, the heart of English Lakeland.

An admirable exhibit of late-flowering Gladioli was shown by Messrs. Hogg and Robertson, Dublin.

Hollyhocks in tall, handsome spikes of varying hues were shown by Messrs. Webb and Brand, Saffron Walden, Essex.

Mr. R. Pritchard, Wimborne, had an interesting lot of alpinics, among which we observed *Antirrhinum glutinosum* and the charming *Bluebell Flower*, *Waldenbergia gentianoides*.

Messrs. Conways, Limited, Halifax, showed a representative collection of herbaceous flowers interspersed with pillars of Roses.

Mr. J. H. Marsden, Malvern Link, showed early-flowering Chrysanthemums and herbaceous plants.

Messrs. F. Smith and Co., Woodbridge, staged herbaceous plants in great profusion.

EDITORIAL NOTICES.

Every department of horticulture is represented in **THE GARDEN**, and the Editor invites readers to send in questions relating to matters upon which they wish expert advice.

The Editor welcomes photographs, articles and notes, but he will not be responsible for their safe return. All reasonable care, however, will be taken, and where stamps are enclosed, he will endeavour to return non-accepted contributions.

As regards photographs, if payment be desired, the Editor asks that the price required for reproduction be plainly stated. It must be distinctly understood that only the actual photographer or owner of the copyright will be treated with.

The Editor will not be responsible for the return of artistic or literary contributions which he may not be able to use, and the receipt of a proof must not be taken as evidence that an article is accepted. Publication in **THE GARDEN** will alone be recognised as acceptance.

Offices: 20, Tavistock Street, Covent Garden, W.C.

NOTES OF THE WEEK.

Our Special Bulb Number.—Now that the season for planting bulbs is once more with us, we shall devote the greater part of our next issue, which will be considerably enlarged, to articles on bulbs for autumn planting. The Rev. J. Jacob, Mr. C. E. Shea, Mr. H. R. Darlington, Mr. F. Herbert Chapman and other well-known growers of various kinds of bulbs will contribute to that issue, for which we anticipate a large demand. In addition to numerous and unique black-and-white illustrations, there will be a coloured plate of Cottage Tulips; but the price of this special enlarged number will, as usual, be one penny.

The National Vegetable Society's Show.—We would remind our readers that the annual exhibition in connection with the National Vegetable Society is to be held this year in the Clarendon Hall, Watford, on Wednesday, October 2. Nearly two hundred pounds in prizes is being offered, and there are classes suitable for both large and small growers. Entries close on the 23rd inst. Copies of the schedule and full particulars concerning the show can be obtained from the hon secretary, Mr. E. G. Quick, Kelmescott, Lockett Road, Wealdstone, Middlesex.

A Good White Phlox.—Now that so much interest is being taken in the herbaceous Phloxes, we ought not to lose sight of some of the older varieties, several of which are not yet surpassed. Among these is the white variety Mrs. E. H. Jenkins. We have had plants of this in flower for nearly seven weeks, and there is still a good sprinkling of blossoms. For its long period of flowering alone this Phlox is well worth growing. The blossoms are moderately large, pure white, and the flower-trusses have a good branching habit. It increases very rapidly, and is all that a good Phlox ought to be. It was raised some years ago by our esteemed contributor, Mr. E. H. Jenkins.

Importation of Potatoes to Jersey.—The Board of Agriculture and Fisheries desire to inform Potato growers and merchants that the States of the Island of Jersey have adopted an Act authorising the importation of Potatoes from the United Kingdom, as from the 17th ult., on the following conditions: Each consignment must be accompanied (a) by a declaration by the shipper indicating the farm where the Potatoes were grown and certifying that no case of wart disease of Potatoes has occurred on such farm; and (b) by a certificate of the Board of Agriculture and Fisheries, the Board of Agriculture for Scotland, or the Department of Agriculture and Technical Instruction for Ireland, as the case may be, to the effect that no case of the said disease has occurred within five miles of the farm where the Potatoes were grown. Intending exporters of Potatoes to Jersey should forward the declaration from the grower of the

Potatoes previously referred to when applying to the Board for a certificate. The declaration should state the name of the farm on which the Potatoes were grown, the parish in which it is situate and the nearest post town, in order that its exact position may be readily identified.

National Rose Society's Autumn Show.—The annual autumn exhibition in connection with the above society is to be held in the Royal Horticultural Hall, Vincent Square, Westminster, on the 12th inst. In a wet season such as the present it will be particularly interesting to see which Roses are the most satisfactory. Wonderful strides have been made in autumn-flowering Roses during recent years, and there is certain to be a good display.

A Good Hardy Crinum.—In every garden where the Crinum can be accommodated, whether with sheltering wall, greenhouse or fence, if not capable of standing in the open border, the typical *C. Powellii* is worthy of attention for the warmth of its colouring at this season. The rosy red flowers, even if small by comparison with other varieties, are certainly of the decorative order, and, deepening with age, are very attractive in the early autumn.

Sweet Peas Diseased.—At a meeting of the scientific committee of the Royal Horticultural Society held on the 27th ult., Sweet Pea plants from Mr. Dipnall were shown. The specimens were damaged by the "streak" disease, *Thielavia basicola*. Many of the leaves and parts of the stem had also patches of *Botrytis cinerea* growing on them. The roots were poorly developed, and showed signs of some check earlier in the season, probably overwatering in the early summer. As a method of preventing the attack, the deep and early autumn cultivation of the ground intended for next season's crop of Sweet Peas, a very moderate use of organic manure, thin seeding, and the frequent use of the Dutch hoe in place of watering during early droughts are suggested.

Growing Camellias in Decayed Wood.—In the current issue of the *Kew Bulletin* Mr. W. J. Bean, in describing a visit to various gardens in and around Florence, gives the following interesting note about Anthuriums and Camellias: "A visit was made to the School of Horticulture at Cascine on the outskirts of Florence. An interesting branch of activity here is the hybridisation and improvement of Anthuriums, especially of the red-spined section. A group showing some of the best results secured a first prize at the recent International Show at Chelsea. Another interesting culture is that of Camellias in the decomposed wood of *Castanea sativa* (the Sweet Chestnut). This material, regarded here as a substitute for peat, is the brown, fungus-killed wood one sees in hollow trees, and Camellias, which will not grow in the ordinary soil, thrive well in it. *Acacia dealbata* also fails in the ordinary soil and is grafted on *A. longifolia*, which succeeds in it."

CORRESPONDENCE.

(The Editor is not responsible for the opinions expressed by correspondents.)

A Hardy Pelargonium.—In THE GARDEN for August 31, page 433, Pelargonium endlicherianum is noted as being the only species possessing any claim to hardiness. Perhaps some of your readers would be interested to know that *P. triste*, although not so showy, will survive our winters at the foot of a warm wall. I saw the species a fortnight ago in the Cambridge Botanic Garden growing by a greenhouse wall, where I know it has existed for at least ten years. It was then carrying two spikes of its curiously-marked, brownish yellow flowers well above the pretty lacinated foliage. Like *P. endlicherianum*, it dies down to the ground each winter.—E. J. ALIARD

Roses with Bad Habits.—I am more than astonished to note on page 422 "H. P." denouncing that grand garden Rose General Macarthur as being subject to mildew. We have only had it for two seasons, but each of these has been so entirely different from the other that no better test could be devised for proving the habit of a Rose. Last year it was practically free from this troublesome disease, while up to the present (August 27) not the slightest sign of mildew is to be seen this year, while some other varieties are rather badly touched. Only the other day a gentleman visiting here remarked that this Rose was worth cultivating for its foliage alone. Is not "H. P." confounding General Macarthur with some other variety?—C. B., *Linthgow*.

Clarkias and Godetias.—In "Notes of the Week," issue August 24, the references to these plants are interesting and instructive. The Clarkia is becoming a very popular annual, both for filling borders and in a cut state for vases, the tall varieties producing fine spikes of blossoms peculiarly adapted for placing in the tall vases now so extensively used. During the present summer I have noticed that Clarkias have been very effectively used in dinner-table competitions at some of our shows. I first saw a table so decorated about four years ago, and was much pleased with the effect. The deep and light pink, purple, salmon, rose and white varieties are very charming. The Godetias are equally beautiful, and should certainly be freely used in a cut state, as the flowers last so long in vases. I was not aware, before reading the note referred to, that they would last such a long time in a fresh condition.—SHAMROCK.

Puschkinias, Snowdrops and Winter Crocuses. I was glad to find from the note on Puschkinias, page 421, issue August 14, that I am not the only ignorant amateur who till recently was unacquainted with these fascinating little flowers. I got a few last autumn and (being a genuine "amateur") planted them in a small wooden box for fear I might waste one of my few precious bulb bowls on something unsatisfactory. However, as soon as the first spike of bloom opened, I armed myself with a (kitchen) fork and promptly transplanted them into a blue and white china bowl. The accommodating little bulbs bore "the move" without flinching, and, what is more, continued to flourish for quite a long time in the window of a room lighted by gas! This year my bulb-merchant has an order for a hundred, which I intend to put in little open lattice-work blue and white Japanese Fern pots, and I hope to have some very dainty specimens on the flower table in my "pleasant parlour" in the early spring. I can

endorse Mr. Bowles' advice to plant Snowdrops early (just like *Lilium candidum*); in fact, I lifted and replanted mine in June before their foliage had quite faded away, with the happy result—after the failures of many years—that I can now proudly say I have enough for my small garden, in the shape of a border about twenty feet long by over two feet wide, entirely filled with Snowdrops (increased from about two hundred planted eight years ago). I am surprised Mr. Bowles omitted *Crocus Imperati* from his list (most of which I have tried), for, so far as my pocket has permitted me to experiment, it is much the best of all, and can be relied on to furnish some pretty bowls for the table by Christmas-time without any artificial heat. It also flowers freely and continues long in bloom in a room, a great consideration with—"ANNE" AMATEUR.

Judges Judged.—The recent correspondence in THE GARDEN on this subject has been interesting and, I think, instructive in many ways, but more particularly perhaps as demonstrating the importance attached by the writers to a strict adherence to the letter and spirit of the rules laid down in the schedule for the information and guidance of exhibitors and judges alike. There are still one or two points on which a slight difference of opinion exists among judges. One of these, and I think the principal one, was incidentally mentioned in Mr. Hudson's letter on the subject in your issue of last week. I refer to the subject of disqualification. It is always a delicate matter, and one which judges approach with reluctance and regret, because it is sure to cause disappointment, and even sometimes pain, to one or more of the exhibitors. Perhaps the most frequent cause of disqualification is the inclusion of too many (or too few) plants in a collection for which a distinct number of plants is asked for, or, in the case of fruit, in dishes of Peaches, Nectarines, Apples, Pears, &c., where six fruits are asked for and where seven or more are included. It is suggested that the better way of dealing with these mistakes is to request permission from the authorities of the show to draw the exhibitor's attention to this fact, in order to give him an opportunity of correcting the mistake. It is a stupid mistake to make, and one for which there can be no excuse, and I doubt very much if either the judges or the authorities have power legally to redress the mistake once the exhibit has been placed on the stage and out of the exhibitor's hands. Certainly if such an exhibit is awarded a prize, the prize-winner next below has, in my opinion, a valid reason for protesting against an award being given to an exhibit which had been so favoured by the judges. I am strengthened in this opinion by the fact pointed out in Mr. John Wright's letter—that it is quite competent for the judges to recommend to the authorities, in all cases where they are convinced that the error has been a genuine and accidental one, that an extra prize be awarded to the disqualified exhibit more or less equivalent to the prize lost in consequence of the error, so that the exhibitor is punished for the error but suffers little or no material loss. If this rule were rigidly carried out, there would be fewer mistakes of this sort in future.—O. T., V.M.H.

The Sporting of Californian-grown Sweet Peas.—I read with pleasure the article under this heading in the issue dated August 24, page 423, which is very timely. This season has given many growers cause for complaint in finding foreign stocks untrue, and I trust that our experts will come along and voice their views in the matter,

and thereby assist in trying to find the real cause of the trouble. It is interesting to hear that the mixed stocks are all Californian-grown. This certainly advances us one step, which should prove helpful in locating the cause. We must, however, try to probe the matter further, and to this end I contribute my observations. I have noticed that the cross-fertilisation theory is always advanced when this subject is discussed, and while it may to some extent actually happen, it would not explain all the mixtures that we get from Californian stocks. To cite a case in point, I have this season had a blue bicolor in Dainty Spencer, Etta Dyke and Mrs. Hallam, and an Elsie Herbert type in Etta Dyke and Asta Ohn. Now the seedsman, who is the grower, assures me they are sports, which seems truly remarkable, especially so when it is considered the same (sports?) appear in three and two cases respectively, and, it should be noted, in colours that are far apart. Despite the assurances that Californian stocks are as severely rogued as English, I think it must be admitted that the conditions under which the former are grown are not so favourable to true stocks as the English, although the seed is, generally speaking, better harvested and germinates excellently. The conditions referred to are the warm climate, which naturally forces the flowers out so quickly that they are over and seed-pods forming in a very short time, thereby giving little opportunity to the grower to get over his acres of plants with that regularity that is essential, especially so when the plants are on the ground. Further, quick ripening of seed means that some will fall before it can be gathered, and will come up next season. As we all realise that we cannot do without the foreign seed, we can only hope that something further will be done to ensure stocks being produced that will give a higher percentage of true flowers than they at present do.—GEORGE TUCKER.

— The great disappointment I have experienced in regard to some varieties I have grown this season leads me to think that probably some of the seed supplied to me—and that, too, by a firm of great repute in this country—must have been Californian-grown. This is the conclusion to which I am driven since reading the article in your issue of the 24th ult., page 423, or, rather, by the reading of that article together with knowledge gained from observations made during many years, added to what I noticed at the time about the seed purchased as stated and the behaviour of the plants since. The variety Clara Curtis, from ten seeds sown, gave one plant bearing maroon flowers similar to Othello, the other plants true; but Helen Lewis was far worse, showing no fewer than five poor varieties and only one plant bearing flowers nearly like the original, and so I might go on in regard to another half-dozen at least. I am one of those who "have bluntly stated that the stocks were mixed," and to that explanation I shall hold until some other has been clearly proved to apply to the case. No doubt there are among raisers and others those who, if they would, "could a tale unfold" upon this subject. In my opinion nothing short of an investigation on the spot, that is, in California itself, will be productive of real satisfaction to the disappointed growers and irritated merchants of this country. To carry out such a bold scheme, an expert should be chosen by one of our great societies, say, the Royal Horticultural Society or the National Sweet Pea Society, the funds being provided partly by those societies and partly by the great firms most affected—WILLIAM ROBIN, *Hawsham, Lincoln*.

A Graceful Shrub (Cercidiphyllum japonicum).

I am rather interested in the question of the hardiness of *Cercidiphyllum japonicum*, which, I am told, is not quite hardy. Young plants have stood the last two winters with me, and do not appear to have suffered at all. It is, however, one of the subjects which looks as if it would be easily injured in appearance by high winds, and a storm a month or so ago rather defaced one of my plants by knocking about the leaves. It is rather a graceful-looking shrub at present, and one would like to know of its hardiness. My plants are only about four feet high, but it is said to grow to 20 feet in its native country.—S. ARNOTT.

Three Crops of Pears in One Year.—It is a common occurrence the blossoming of a Pear or Apple tree late in the summer while fruits are at the same time coming to maturity on it. This year I have a Pear tree, Durondeau, trained as a cordon, bearing fruits set at different times—the first set on an ordinary spur, the second on young wood growing from a spur higher up, and the third formed on the leader, about four weeks intervening between the three lots of flowers. Undoubtedly it is all to be accounted for by the exceptionally hot summer of last year, which matured the wood and buds so thoroughly.—AVON.

Nelumbium Flowers at Christchurch.

I was greatly interested in the note on *Nelumbium speciosum* which appeared in THE GARDEN of August 10, page 397. I am enclosing a photograph of a plant of *Nelumbium speciosum* roseum growing in the aquatic-house in these gardens, which you may be able to reproduce in THE GARDEN. The leaves of our plant are quite 18 inches in diameter, and the flowers, which are of a beautiful rosy pink, average 10 inches in width, while the plant itself is nearly seven feet high and is growing in a tank 18 inches in depth. The *Nelumbium* seems to revel in a rooting medium composed chiefly of turfy loam and cow-manure. We succeeded last summer in flowering the variety album. This year the plant is not so robust, but is now making some good growths. I might mention that the temperature of the water in the tank during the growing season is maintained at a minimum of 70°, and a fresh supply of water is run in daily. Here also the blue *Nymphaea stellata* and several of its varieties do well, flowering profusely all through the summer.—JAMES MURRAY, *Sopley Park Gardens, Christchurch.*

FORTHCOMING EVENTS.

September 9.—National Chrysanthemum Society's Floral Committee Meeting at Carr's Restaurant, Strand. United Horticultural Benefit and Provident Society's Committee Meeting.

September 10.—Royal Horticultural Society's Exhibition at Vincent Square, Westminster. Lecture by Miss Troyte-Bullock on "Cape Pelargoniums" at three o'clock.

September 11.—East Anglian Horticultural Club's Meeting. Royal Caledonian Horticultural Society's Autumn Show (two days).

September 12.—National Rose Society's Autumn Show at Vincent Square.

September 14.—Galashiels Flower Show.

THE ROSE GARDEN.

ROSE CONRAD F. MEYER.

HAVING grown this useful town Rose from the very first, I think I can enlighten some of those who complain of its behaviour. It is so valuable under some conditions that I feel it is possible it may be unsatisfactory where Roses thrive without any very particular care, and so I will tell of the conditions where it thrives and flowers freely, and also of two or three cases where it is decidedly unsatisfactory.

In a town garden near the sea in Yorkshire, where ordinary Roses refuse to thrive, this hybrid of *rugosa* has proved quite invaluable, flowering each year more abundantly and giving also some

THE SACRED LOTUS (*NELUMBIUM SPECIOSUM*) IN THE GARDENS AT SOPLEY PARK, CHRISTCHURCH.

very bright flowers in the autumn. The soil is strong clay, the climate generally cool and the growths extremely vigorous, so that my aim has always been to ripen the long summer shoots and plump up the flowering eyes on the upper half of the shoots. As it happens, I always leave this garden in October, and so before I leave I always prune and train this Rose. From the month of August I suppress entirely those soft, strong young shoots that are so apt to start from the base of the year's shoots, and during the summer I cut out the shoots that flowered most freely in June at the point where the first strong growth has been made, keeping, of course, all vigorous growths. In October I deliberately prune and cut out all weak and ill-placed wood, and tie out all the best and longest new shoots, either to a railing or an espalier, and still more frequently tie down many vigorous shoots over *Olearia Haastii* bushes, when the next spring they cover that hardy seaside

evergreen with quantities of fine flowers. I notice that my big bushes flower more freely than other folk's, and I have, after six or seven years' close watching, come to the conclusion that this early thinning, pruning and tying out is a great factor in the making of flower-buds, as growth goes on so late in autumn in this Rose. Of course, it flowered better than ever this spring and early summer after last year's heat and drought, but with care in carrying out the details I have given, I am sure the amount of bloom is increased in all seasons.

As all the world knows, *rugosa* Roses thrive best in sandy and peaty soils, so I strongly recommended this Rose to those who garden in the smoky districts of Yorkshire and on the light soils so prevalent there. To my great surprise I have found that though the plants grow very vigorously, they do not flower well, and the foliage that is so splendid and weather-proof by the sea soon drops and is affected by spot, as your correspondents complain, so that it is of no value in those places, even with considerable care. One reason I think is that it suffers if its roots get thoroughly dry in summer, and so makes still more late autumn growth; but I am inclined to say that it flowers much the best in a clay soil that is well impregnated with lime—a very curious thing when one considers its parentage.

Before I finish this little article I should strongly recommend another *rugosa* hybrid to your readers, for I do not believe it is known as it deserves. It is M. Gravereaux's *Parfum de L'Hay*, a red-flowered Rose, extremely sweet, as its name implies, with superb foliage and growth, which sends up enormous shoots in the summer that are crowned in September with large panicles of flowers in profusion. The flowers in autumn are brilliant in colour, and will pass muster anywhere as good blooms of that best of Roses, General Jacqueminot. I shall never forget my surprise at its beauty last year, and even this year it promises to repeat it if the weather will permit; but these cold drenching rains and cloudy skies must in the long run try even so hardy and vigorous a Rose as *Parfum de L'Hay*.

I am reminded by foreign friends that the best stock for strong-growing Roses on light and sandy soils is the Japanese Rose, *Rosa rugosa*. As in the case of the Briar, young seedlings, which can be grafted or budded below the collar, are the best subjects for using as a stock; but to the amateur who probably has plenty of strong suckers springing up at some distance from his bushes of *rugosa*, he will find he can utilise them easily by pulling them up from the soil till a portion of the smooth underground stem is exposed. He can then bud on it, and, after the maiden has flowered in due course the next season, he can sever it and plant it where he chooses. The Dutch find this stock far the best in their light and sandy soils, and so I believe it would be of use in England, especially in smoky districts and on dry soils.

Scarborough.

E. H. WOODALL.

[At least one large firm of Rose nurserymen in this country uses the *rugosa* stock for standard Roses, and we understand that such plants do well in almost any soil and transplant very easily.—ED.]

ROSES IN TOWN GARDENS.

IN "Notes of the Week" for the issue dated August 24 (page 421) is a short paragraph *re* Roses in London. That Roses can be grown in London and its immediate suburbs has been proved over and over again by the beautiful boxes of exhibition blooms staged annually at the metropolitan exhibition of the National Rose Society. I have seen really first-rate Roses in the class for those grown within eight and also within six miles of Charing Cross, and I take it we may style such a radius as town. If a double and rather balled-in variety like Caroline Testout opens freely in Hyde Park during such a sunless and dripping season as the present

more especially as we now have such a good type of free growth and opening to be found in the varieties named and others with the same characteristics. Thoroughly examine your ground and make that right; then you may reasonably look for a fair measure of success. A. P.

ROSE ENTENTE CORDIALE.

ALTHOUGH this beautiful Hybrid Tea Rose has been in cultivation in this country for two or three years, little has, so far, been written about it, yet it is one of the best for garden decoration, and should, if cultivated for the purpose, give excellent flowers for exhibition. It is a moderately

flesh, pale pink to brightest purple, and pale primrose to rosy salmon. The leaves of the Peony are a most useful autumn foliage for decorating, often turning to a beautiful red and bronze shade. Yellow Narcissus bulbs dotted among the plants give a very charming effect in early spring. Pæonies can be planted now or within the next few months in rich deep soil, adding plenty of well-decayed horse or cow manure. In dry seasons, and as soon as the buds are formed in early spring, they must be well soaked continually with weak liquid manure. Being strong, robust-growing plants, they soon impoverish the soil. Plants that are well established should have a trench dug out around them, partly filling it with well-decayed manure and the surface space with soil, treading the whole very firmly. Other suitable plants for shady places are *Primula bulleyana*, *P. sikkimensis* and *P. japonica*, hardy *Spiræas* in variety, *Funkias*, *Primroses* and *Polyanthuses*, *Vincas* (*Periwinkle*) and hardy Ferns. J. L. E.

SEASONABLE NOTES ON CARNATIONS.

Rooted Layers.—By the present date all layers correctly cut and pegged down with proper care in mounds of specially-prepared soil will, provided they have had necessary attention subsequently, be excellently rooted, and the question of where they are to be wintered must have immediate consideration. Notwithstanding the fact that the Carnation is a hardy plant, there are certain circumstances and conditions which render it wise not wholly to rely on plants put out in beds and borders in September. For example, in low-lying damp gardens, where the soil is on the heavy side, it is more than likely that the winter losses among plants in the open will be serious, not because frost has injured them so much as because they could not withstand the effects of a combination of damp atmosphere and frost. Again, numbers of modern varieties, and more particularly so those of the beautiful yellow-ground section, have not as sound a constitution as the older varieties, and as many of these are on the expensive side to purchase, it is not wise to risk the whole of the stock in the garden. We are, therefore, forced to have recourse to potting a certain number for wintering in cold frames. It is, of course, necessary for every individual cultivator to decide on the merits of his own case what system he will choose; but the desirability of having some reserve, even when the general conditions are apparently favourable, must never be overlooked. Rather more trouble is necessarily involved, but this will not weigh heavily with the man who aspires to achieve the finest results.

The Soil in Beds.—Depth and friability are essential to success, and it is obviously of decided importance that enough food shall be present to carry the plants on through the following summer. Thus the digging—it really ought not to stop short of bastard-trenching—must be thoroughly accomplished, and a sufficient quantity of sweet manure must be mixed into the second spit to provide plentiful supplies of food next season. This is buried well down to avoid contact with the roots, which I consider to be most undesirable. In some instances, no doubt, the soil will contain enough lime; but in the majority of gardens this will not be the case, and the grower will be wise who decides to add some in the convenient form of crushed mortar or lime rubble. Where it is inconvenient or impossible to use any organic

AUTUMN BLOOMS OF ROSE ENTENTE CORDIALE, A BEAUTIFUL HYBRID TEA OF RECENT INTRODUCTION.

is proving, we can surely look forward to a better measure of success when making use of more suitable varieties, and my present object is to name a few of the best of these.

A free-flowering white (in addition to Fran Karl Druschki, which is so well known as to need no comments here) I would select is Molly Sharman Crawford. This Rose is a good grower, exceptionally free and persistent in blooming, and invariably opens well. For deep scarlets I would choose General Macarthur and Grüss an Teplitz. In addition to Caroline Testout, we find freely-opening pinks in Lady Ashtown and Killarney, while for deep yellows and orange shades few will expand more readily than the exquisitely-scented Mme. Ravary and Marquise de Sinety. Edu Meyer and Theresa Bevan are a couple of salmon yellows that are free in every way and open well. There are many others; indeed, quite a list could be made up of varieties I have seen staged in the two classes for London which have been well represented during many and varied seasons.

So long as one confines the selection to really good and free growers, keeping rather closely to those with few petals, there is no more reason why an ordinary garden should not produce fairly satisfactory Roses in and near to London as is the case with many other plants and trees. With less smoke and fog owing to the use of electricity when compared with a few decades ago, we should even have a better chance of success than before,

vigorous variety and flowers very freely, the large, beautifully-shaped blooms being produced separately on good stems. The colour of these is clear pale cream, and I see that most nursery descriptions state that the edges of the petals are tinted carmine, but this feature has not developed on my plants. The blooms are very fragrant, and this, with their beautiful form and purity, should secure for this Rose a very warm reception. The foliage is hard and good, and so far, despite the wet, I have seen no mildew on it. Good as Entente Cordiale was at the first or summer flowering, the second crop has been even better, and the illustration shows two blooms that were cut at the end of the third week in August. H.

THE FLOWER GARDEN.

NOBLE PLANTS FOR SHADY PLACES.

MOST gardens have shady places beneath trees or under walls where very little sun can penetrate. In these places Pæonies, with their most beautiful varied colours, and some with delicious fragrance, will grow luxuriantly. The flowers last much longer than if exposed to full sunshine, and it is very essential the plants should have moisture. Hybrids of recent introduction bear very large flowers, and include colours ranging from white to pale

mannes, the advisability of forking into the top spit a little concentrated fertiliser may well be considered; but the fact that it is just as easy, if it be not a trifle easier, to do more harm than good with it at this season of the year must not be overlooked. It is, however, improbable that anything other than advantage could accrue upon a mixture of superphosphate of lime and kainit in equal proportions at the rate of 3oz. to the square yard. Basic slag, very finely ground, has proved most beneficial in my own garden, the dressing to each square yard being 4oz. worked into the top spit.

Potting Plants.—The first thing of importance in this phase of Carnation culture is to prepare enough small pots. They must be perfectly clean, and the provision for drainage must be efficient. It is, of course, true that the amount of water demanded during the winter months will be small, but it is necessary to see that there can be no danger of the slightest stagnation, or failure is sure to ensue. Therefore have one good crock over the hole in the bottom of the pot, and put round it in such manner that the passage of water will be facilitated two or three other pieces, and cover with coarse moss or a little of the rougher parts of the compost which, it will be remembered, it was suggested should be mixed two or three weeks in advance of actual use. In potting, firmness is desirable, but ramming in with a potting-stick must be deprecated, as it prevents the satisfactory extension of the roots. The soil ought to be pleasantly moist when used, and it should be kept in that condition subsequently. F. R.

DAFFODIL NOTES.

SOME MODERATE-PRICED DAFFODILS FOR SHOWING.

(Continued from page 443.)

Division IX., Poeticus Varieties.—I have lately written some notes on these. Almost all of them need to be caught at the critical moment if they are to be staged flat without "buckling." One must, accordingly, have more varieties in proportion to pick from than would be wanted in other sections. This is the most important bit of advice that I can give to would-be exhibitors. The corollary is spread out what you have over as long a flowering-time as possible. My earliest is Chaucer (April 4, 1912), and my latest is the lovely pale green eyed Tom Hood. It opened this year on April 18, fourteen days after Chaucer. Here are a nice eighteen. The first six are the more expensive ones: Acme (all-red eye), Kingsley, Matthew Arnold, Tennyson, Ruskin, Timon, Cassandra, Homer, Horace, Virgil, Laureate, Minerva, Rudyard Kipling, Ibis, George Herbert, Oliver Goldsmith, Almira and Orange Ring. From these it should be possible to cut a good six in almost any year. When Kestrel, Socrates and Snow King become cheaper, they may be added.

Class X., Double Varieties.—Little need be said of these. The new ones are too dear and seldom, if ever, seen in competition. I wonder how many are sold at such high prices. Inglescombe, Argent, Dubloon, Sulphur Phoenix, Apricot Phoenix, "Red and Gold" and Volcano are among the best; but the last three are expensive. Each of them is beyond my "moderate."

Class XI., Various Species and Hybrids.—Much as I like some of the little gems that this division contains, and with all respect to

Mrs. Johnston of Biddeford, who offers a prize at the "Midland," I do not think they are the things to be shown in competition. To me they do not mix, as people say. A non-competitive little group would be charming and instructive, but not so if staged with "show" flowers. JOSEPH JACOB.

THE ROCK AND WATER GARDEN.

A BEAUTIFUL HAREBELL.

(*CAMPANULA HOSTII*.)

FEW hardy plants possess greater attractions than the Campanulas, from whose number we can choose many beautiful flowers either for the border or the rock garden. Some are excellent for either purpose, and among them none is better than *C. Hostii*, which may be called a glorified form of our common Harebell, with much larger and finer flowers of a deep purple, and a more sturdy plant in every way. This Harebell, figured in the accompanying illustration, is referred to by authorities as a variety of *C. rotundifolia*, but

growing well in ordinary soil, and in summer giving plenty of flowers for a long period, these lasting much longer in partial shade than in sun. S. ARNOTT.

THE BEST SAXIFRAGES AND HOW TO GROW THEM.

Just as the genus *Saxifraga* is by far the most important race of hardy alpine plants, so is it the most replete of species, to say nothing of that equally great following of varieties which, combined, go to make the task of the amateur or beginner a most difficult, if not an impossible, one in making a selection of the best. Nor is the task rendered the more easy by the majority of hardy plant dealers, who appear to regard their duty complete by affording descriptions of a most meagre kind and the price at which they are to be had. How confusing, not to say embarrassing, all this must be to the amateur need not be dwelt upon here, and in the circumstances no apology is offered for directing attention to some of the more distinct. By the "best *Saxifrages*" is intended those that with a little intelligence and care—following always the teachings of the instructor by the way—may be grown by all, whether the desire be in the

CAMPANULA HOSTII, A NEAR RELATIVE OF THE BRITISH HAREBELL AND A CHARMING PLANT FOR THE ROCK GARDEN.

is so distinct that it is difficult for the gardener to accept this reference. It is a much finer plant in every way, and one is glad to see from his book, "My Rock Garden," that Mr. Reginald Farrer, who knows these Bell-flowers so well, evidently agrees with the opinion that it is very distinct. It grows with me about a foot high, has a sturdy, firm, yet elegant habit of growth, and gives sheaves of handsome large purple bells. It evidently comes true from seeds, and can also be increased by division. It is an excellent rock garden or border plant, and is most obliging in its disposition,

direction of pot-grown examples for alpine-house or frame, for the rudest rockery bank of a couple of feet or so in height, or for the more elaborately-arranged rockery itself.

Regarded broadly, the genus divides itself quite naturally, for the most part, into two or three main groups or sections, of which the silvers or "encrusted" forms, the "mossies" and those bolder-leaved sorts which constitute the Megasea section are the most important. To render these notes of greater value, it is proposed to treat each section separately, and I take the encrusted section

THE "SUNSET" BORDER AT KENTFORD. THE FLOWERS ARE ARRANGED HERE TO REPRESENT THE COLOURS OF THE SETTING SUN.

first by reason of their beauty, their outstanding superiority and intrinsic worth. Culturally, it may be remarked of many of these that while they do not object to living upon the fat of the land—i.e., comparatively rich loamy soils—they incline to a greater or more pronounced silvery hue when grown in deep sandy loam to which old mortar or ceiling plaster—one of the best possible constituents of a Saxifraga soil—has been freely added.

Saxifraga Aizoon.—A good silvery kind and the type of an invaluable host flowering in May and June. All the varieties are of free growth, and as carpeters of the soil are most reliable. *S. A. rosularis*, white; *S. A. lutea*, palest primrose white; and *S. A. rosea* are the best. The last-named is a gem, whose rosy flowers on crimson peduncles or stems appeal to all. *S. A. balkana* is a delightful plant, the big whitish flowers being copiously spotted with pink. Any good loamy soil.

***S. apiculata*.**—A yellow-flowered kind of the freest growth and easiest culture in good sandy or even stony soil. The plant forms a cushion-like tuft, which from February to April is mantled with the clusters of blossoms on 3-inch-high stems. *S. a. Maylii* is a late-flowering form of this indispensable plant.

***S. burseriana major*.**—The prince of the white-flowered silvery Rock-foils. From a spiny grey tuft in February rise solitary stems bearing flowers of sparkling purity the size of a shilling. *S. b. Gloria*, *S. b. magna* and *S. b. speciosa* are other choice varieties of this set, valuable one and all to the cultivator of a select few because of their successional flowering. Deep, gritty loam and perfect drainage are required for all.

***S. cochlearis*.**—I look upon this as one of the most beautiful of a great race. It flowers in June, when the nearly foot-high panicles are a cloud of snowy pink-peppered blossoms. *S. c. major* is of larger growth in all its parts, while *S. c. minor*, also known in gardens as *S. valdensis* (though not the true plant), is a miniature of the first, whose elegant sprays of white please all-comers. This little tribe have a conspicuous beauty of their own even when not in flower.

S. rocheliana and its variety *coriophylla* are of the tufted set, and form cushions of growth, studded

with snowy flowers on 4-inch-high stems in April and May. These are most desirable and easily grown.

S. Cotyledon and its variety *S. C. pyramidalis*, whose giant white plumes are seen in many decorations, are indispensable to all. The natural flowering period is June and July, but the plant is forced in flower much earlier. *S. c. icelandica* is a variety 3 feet high, and appears in the last-named month as a fitting finale to a great race. Sandy or gritty loam.

S. erustata*, *S. cristata*, *S. pectinata and a rather numerous nearly-allied following known in nursery gardens are all neat-habited silvers flowering in May. They are highly attractive and white-flowered. Sandy or gritty soils.

S. Elizabethæ is not a silver, but a great beauty, producing a carpet of spiny grey-green leaves and big primrose yellow flowers in clusters on 4-inch-high stems in March and April. It is a most abundant bloomer, and grows freely in light, well-drained soils.

S. saneta is also a soil carpeter, and if freely grown, flowers well. On dry banks it becomes starved. The flowers and anthers are rich yellow and appear in March and April.

S. Hostii is one of the most valuable of the silvery kinds, a plant free in growth and readily increased. Its flowering sprays are 15 inches high. It is most effective in colonies, and flowers in April and May. Any good gritty loam.

S. kolenatiana is not unlike some of the Aizoon forms, but with flowers of rosy pink. It is a May-flowering kind and fond of chalk or limestone.

THE SUNK GARDEN AT REGAL LODGE, AS SEEN FROM THE LOGGIA.

S. lantoscana and its variety *S. l. superba* are in every way excellent silvers of the long-leaved set, and produce clustered racemes of white flowers on 6-inch-high stems in April and May. No selection, however small, would be complete without these. Gritty loam of good depth and free drainage.

S. lingulata.—A most valuable silvery kind, whose well-marked leaves and snow white flowers appeal to all. The flowers appear in May and June, and there is an elegant airy grace about the plant which marks it well. Botanically, this is the supposed type of the last-named, though in nursery collections they are kept distinct. It is an exceedingly beautiful Saxifrage.

modified *burseriana*, appear in February. The plant is happy in any light, sandy soil.

S. scardica obtusa.—A most valuable white February-flowering sort of about four inches in height. The plant is of quite easy culture, grows freely, after the manner of *S. rocheliana*, and is in every way desirable. Coming rather near this, but even earlier in flower, is one called *S. Kestonii*. It is valuable by reason of its time of flowering. *S. scardica* (true) is a rare plant, flowering in March or early April, and is quite distinct from the above.

S. Boydii is the queen of yellow-flowered Saxifragas and a rarity for the specialist. A well-grown plant is always a great attraction to those who love the Saxifragas. Two other yellow-flowered gems of nearly-allied parentage

THE GARDENS AT REGAL LODGE, KENTFORD.

FROM the time that one steps out upon the paved terrace until the survey of the entire garden has been completed, the visitor to Regal Lodge Gardens, Kentford, must feel that he is in an enchanted garden that has been designed in perfect taste and laid out with consummate skill. It is, in fact, an artist's garden, perfect in point of colour and grouping. Moreover, it is a garden possessing many features, each of which blends unconsciously into the next without undue formality or any leaning towards overcrowding.

THE PAVED GARDEN AT REGAL LODGE, WITH THE ITALIAN GARDEN IN THE BACKGROUND.

S. longifolia.—The great Pyrenean Rocktoil, whose huge, silvery grey rosettes of leaves spread out to 8 inches or 10 inches across. In any stage this species is unique. The panicles of flowers rise to 20 inches or 2 feet high, though seedlings may take years to flower. After flowering the typical kind dies, but a variety, *S. l. prolifera*, which produces offsets, is more permanent. The plumes are white, faintly spotted with pink. June and July flowering. Deep, gritty loam, preferably in rocky fissures or crevices.

S. Salomonii.—In the entire race there is not a greater beauty than this, though it is not free flowering. As a silvery grey carpeter of the soil it is unique. Its flowers, which are those of a

are Faldonside and Cherrytrees, and, given pot culture, are highly desirable.

S. Paulinæ is a yellow-flowered form 3 inches high, whose good growth and free flowering promise well. It is regarded as a possible rival to the above. February and March.

S. Boydii alba, if only 2 inches high, has glistening white flowers of great beauty in February. Splendid little plants of this are occasionally shown at the Royal Horticultural Society's spring shows, and always meet with a hearty reception. Gritty loam and pot culture. Next week I hope to deal with other members of this important race.

E. H. JENKINS.

(To be continued.)

Looking from the terrace towards the Italian garden, one obtains a good impression of the delicate colour tones obtained by careful planting. In the foreground is a sunk garden in shades of blue and silvery pink. A bed of blue Lavender is interspersed with pink Lilliums, surrounded by beds of standard and bush Roses and tubs of Hydrangeas, all in soft tones of pink. The low-growing plants between the chinks of paving-stones enter into perfect harmony, for these, too, are in shades of pink and blue, comprising Campanulas, Mossy Saxifragas, Sedums and Sea Pink or Thrift, while here and there a self-sown tuft of white Arabis has firmly established its right to be present. Throughout the garden flowers are grown a little

carelessly, yielding a harmonious blending of colour never to be found in a garden that is prim or too conventional.

As one wanders towards the Italian garden it needs no practised eye to tell that the garden has been designed with a view to making the best of the landscape. A small irregular clump of *Cupressus* guards the approach to the Italian garden, and within it is devoted to a veritable dell of Roses, in which the variety *Lady Godiva* is planted to form a bank on either side.

The Lavender Walk.—Perhaps the most charming feature in the late summer is the paved Lavender walk, a feature we hope to illustrate in a future issue of *THE GARDEN*. Bold lines of Lavender, edged with Thyme, are planted on either side of the walk, while between the paving-stones are innumerable patches of dwarf *Campanulas*, chiefly *C. pulla* and the variety *Miss Willmott*, with bells of silvery blue. The colour combinations of this walk in shades of blue are most pleasing.

It is in the artistic arrangement of the herbaceous borders that *Lady de Bathe*, who has designed the garden herself, is deserving of the highest praise. There is a long herbaceous border with a grass path leading from the Lavender walk to a little flight of steps in grass, whence one is conducted into a well-trained pleached alley of Lime trees. The flower-borders on either side of the grass path are chiefly planted in shades of blue, *Anchusa italica* Dropmore variety and countless numbers of *Delphiniums* being used most effectively. The borders and pathway are covered with arches of Roses. There is no straining after effect, but a careless beauty that compels one to admire as observed on all sides.

A "Sunset" Border.—Perhaps the most charming feature of all is a sunset border. It comprises herbaceous flowers so carefully planted as to produce those pleasing tones of colour seen in the glory of the setting sun. The effect, though novel, is a natural one, and *Lady de Bathe* is to be complimented on the result. The border is arranged in a sweeping curve on one side of a carriage drive. In the centre of the border are seen the warm orange tones and fiery reds produced by the free use of *Gaillardias*, *Monarda*, *Montbretias* and *Lobelia cardinalis*. The colour passes through to lighter shades created by such plants as *Pentstemons* and *Phloxes*, while beyond is the blue of the sky, obtained by *Campanulas* in varying heights, intermingled with *Eryngiums* and mauve-coloured *Phloxes*, passing on to cloud drifts that only *Gypsophila* and *Statiche elata* could produce. The effect is pleasing in the extreme, and only an artist could have conceived such a design.

There are other features in these gardens, such as a new rock garden already planted with many alpine, and associated with a little pool where *Water Plantains*, *Iris* and *Nymphaeas* are all freely grown.

We will bring these notes to a conclusion in referring to the loggia and sunk garden illustrated on page 450. From the loggia one looks upon a sunk garden. There is a Lily pool in the centre, where *Water Lilies* thrive and the stippled stems of *Scirpus lacustris zebrina* produce a good effect in the water. It is a paved garden, and little tufts of *Saxifrages*, *Thymes* and *Sea Pink* grow

between the stones. The beds in this garden are filled with *Roses* and *Lilies*, edged with the lovely mauve flowers of *Viola Maggie Mott*. Suspended baskets are filled with *Ivy-leaved Pelargoniums* and the silvery foliage of *Cineraria maritima*. Large earthenware vases are filled with the double-flowered *Marguerite*, while in the background are standard *Heliotropes* and large *Orange trees* in tubs, and pillars clothed with *Roses*.

THE GREENHOUSE.

THE CAPE COWSLIPS.

(*LACHENALIAS*.)

I would like to say a word in praise of *Lachenalias*. I grow a house 27 feet long by 9 feet wide full of them. I call them my February flowers, for (as I grow them with but little or no heat) they are in perfection then. As is the case with so many

brick red, and some of the *Lily of the Valley* scented species are a curious shade of pale blue. They are easy to grow, and require similar treatment to *Freesias*, but they must never have much heat. Early potting is the foundation of success. To fix a date I would say before September 20. Then give but little water until they are in growth.

After the flowers are over a gradual drying off should be given, followed by a period of rest from May till August. Then the cycle begins again. A good rich porous soil suits them very well. The flowers last a long time in a fresh condition, and they make delightful little pot plants. Six bulbs in a 5-inch or seven or eight in a 6-inch pot are useful sizes. For cutting for decorating the small round dinner-tables that are so fashionable they would, I think, be much appreciated arranged with nice greenery in low vases. They last as well cut as in pots. JOSEPH JACOB.

A BEAUTIFUL GREENHOUSE CAMELLIA.

THE large, red, *Pæony*-like flowers of *Camellia reticulata*, a native of China, make it one of the most gorgeous of spring-flowering greenhouse plants, and few people who see the large plant in the Temperate House at Kew in full blossom fail to appreciate its charm. The semi-double flowers are less formal in shape than those of the various varieties of *C. japonica*, the petals being larger and fewer in number. *C. reticulata* may be easily distinguished from *C. japonica* by its looser habit and longer, narrower, dull leaves. As a pot plant it is not such a success as when planted in a border, for it is apt to form a rather straggling specimen, and flowers are produced less freely than is the case when more generous border culture is available.

NOTES ON GARDEN DESIGN.

THERE are few features of a garden more capable of attractive treatment than garden pavilions. The whole theory of formal gardening is that the garden itself should bear a definite architectural relation to the house, which it encircles and adorns. It follows, therefore, that a garden-house or gazebo which is near the main building should partake of its character, should be, in fact, an outpost which the house throws out into the garden world. The further away it is placed, the less need there is to consider this relationship and the more liberty to the designer to adopt something in a rustic manner. It is rare, however, that a summer-house built of unshaped logs, whether barked or not, is successful as a design. Refinement is a quality as valuable in the garden as elsewhere. The accompanying illustration shows an admirable little house set in the corner of a wall garden at Petersfield and rising well above it. Mr. Inigo Triggs has designed it, so that the room is approached by an outside staircase from the far side of the wall, and the undercroft makes a convenient place for the storage of garden sundries. The treatment of the pavilion in brick and half timber is simple and effective. L. W.

A GARDEN HOUSE AT PETERSFIELD DESIGNED BY
MR. INIGO TRIGGS.

flowers with which one is not familiar, some will think most of them at first sight to be very much the same. So many of them are. These may well be left to the patient worker and specialist to enjoy. They can cull pleasure from the minute differences and improvements which others pass by unnoticed and uncared for. But I think those others may get a great deal of quiet enjoyment from some of the well-defined and distinct varieties, such as *pendula*, *Nelsonii*, *Cawston Gem*, *His Reverence* and *Ruth Lane*. Their popular English name, *Cape Cowslips*, suggests the prevailing colour, but here the resemblance ceases, for the little bells are not bunched up on the top of their stalks, but are arranged all round it like those of the Spanish Wood Hyacinth (*Scilla campanulata*). They are not, however, all of them yellow. *Pendula*, the Christmas-flowering *Lachenalia*, is a lovely

GARDENING FOR BEGINNERS.

HOW TO RAISE SWEET PEAS IN POTS.

SWEET PEA enthusiasts are placed in a similar position to cultivators of Chrysanthemums, as no sooner are the old plants cleared away than preparations must be made for raising a stock of young ones. Cultivators can, of course, raise plants from seeds sown in spring, and very satisfactory results follow when this is done. Many growers, however, prefer to raise the earliest stock towards the end of September in pots, and to put out the resultant plants in favourable weather in March or April of the following year. Certainly every lover of the popular Sweet Pea should raise some plants in pots if he possesses soil of a heavy nature, as it is a great advantage to be able to put out strong plants in such a rooting medium in spring.

The Potting Soil.—This must be quite free from wireworm or other insect pests, and be of moderate richness. Good loam of a fibrous nature which has been cut and stacked about two months should form the bulk. One peck of sweet leaf-soil to a bushel of the above and a small quantity of old manure placed in the bottom of the pots will do nicely. If the loam is of a sandy nature, sand need not be added to it; but if rather heavy, it must be mixed with the compost in sufficient quantity to render all quite porous. Use clean pots (3-inch) and select those that are deep.

Preparing Pots and Sowing Seeds.—Fig. 1: A shows how to place the clean crocks and a little rough compost and rotted manure in a pot; B depicts the space for the compost. C shows the seed buried a little more than an inch below the surface, and D the filled pots placed in an ordinary cold frame on a bed of ashes. If such frames are extra deep, put up a temporary stage on empty inverted flower-pots as shown at E. The soil when used must be in a medium state of moisture and pressed down moderately firmly. Give water

at once, but afterwards be very careful not to over-water, though it is absolutely necessary to good germination of the seeds that the soil be maintained in a consistent state of moisture. F shows a well-cared-for seedling growing freely; G depicts one that has been neglected, germinating weakly in soil that has been kept too dry. Of course, more seeds may be sown in larger pots, but it is better to confine one plant to a small pot. Fig. 2: H shows a weakly plant. Such plants may be strengthened by cutting them down as shown at I, as a young basal growth will take its place as shown at J. A well-balanced young plant is shown at K, and L depicts a plant with all the soil washed from its roots in readiness for transplanting in the flowering quarters in spring.

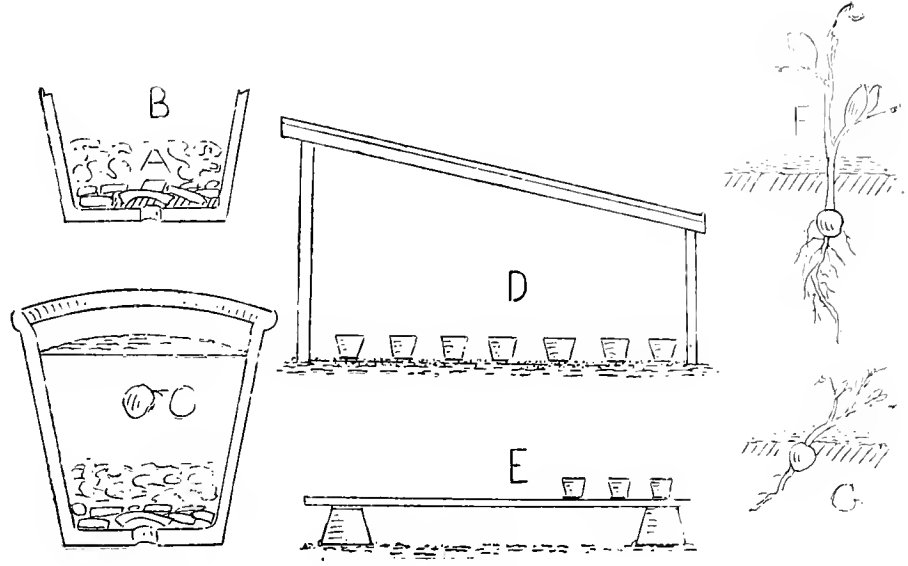

It is not absolutely necessary to wash away the soil, though many cultivators do this with much success. The plants may be put out with soil attached to the roots as grown in the pots. When planted, each specimen should be about nine inches apart every way in a zigzag line as shown at M.

Winter Treatment.—Sweet Pea plants must never be forced. Keep them cool, but safe from exposure to frost. The latter will not kill them, but it will sadly cripple and check the growth. Admit air in abundance when the weather is fine, and prevent the surface of the soil turning green by frequently stirring it. Do not overcrowd the plants, and maintain them in a clean, sweet condition, neatly staking any that require support. Feeding in pots is unnecessary. G. G.

LONDON PRIDE.

(SAXIFRAGA UMBROSA.)

It is often a very difficult matter to provide plants that will thrive in light and also heavy clayey soils in partially-shaded borders, especially in town gardens. London Pride will thrive in almost any ordinary garden soil, its foliage is ornamental, and the flower-spikes are freely produced and look very beautiful in vases. In borders where the soil is fairly rich under the shade of trees, the flower-stems grow 18 inches high and spread out in proportion. Such are grand for cutting. As edging plants to shaded borders or those in the open these plants are sure to succeed. Grown in clumps on rockeries they look charming. Every year the clumps and edgings spread considerably, though there is no difficulty in keeping the plants within proper bounds. There are now plenty of small side growths, and in some instances they have already rooted into the soil. Advantage should be taken of this to remove the side growths in question, and to transplant them either in a nursery bed or in their permanent positions. So treated they will get well established before the winter comes. SHAMROCK.

I.—SHOWING HOW TO PREPARE THE POTS AND SOW THE SEEDS.

2.—GOOD AND BAD SEEDLINGS. WEAK PLANTS MAY BE CUT DOWN AS SHOWN AT I.

GARDENING OF THE WEEK.

FOR SOUTHERN GARDENS.
The Flower Garden.

Annuals.—Where the custom of sowing seed of the many annuals for flowering early next season is practised, the present is a good time for doing so, as then the plants will attain a good size for wintering well and will give a fine effect long before those sown early in the spring of the year. The best plan is to sow in rows and thin to prevent overcrowding; then transplant to their permanent quarters. *Eschscholtzias*, *Nigellas*, *Corntowers*, *Godetias*, *Nemophilas*, *Collinsia bicolor*, *Erysimums* and *Poppies* are a few subjects that will fill many a gap with a bright display, and vacant places in the borders when cleared may be planted with these subjects.

Bulbs.—As soon as the work of planting can be put in hand after the receipt of the bulbs the better, whether they are to be grown in the garden proper or planted for natural effects under trees or in the many parts of the pleasure grounds. Where they are grown in the garden, whether for the supply of cut flowers or no, the ground should be well worked, and the addition of some well-decayed farmyard manure and road scrapings, if the soil is heavy, will prove an advantage. In narrow borders devoted entirely to them they look splendid when in flower if planted in lines, varying the distance between the rows according to the size of the bulbs, the same governing the depth of planting. For naturalising, the addition of a little new soil will generally prove an advantage except on very fertile land, and planting may be carried out by means of a bar or spade. This work is well worth a little extra trouble, as, all being well, the effect will be noted for years.

Plants Under Glass.

Arum Lilies.—These have had a good rest now, and those that were planted out are particularly in need of potting; but unless an increase of stock is required, I prefer to rest them in their pots. If these were potted anew last year and carefully attended to, little else will be required other than a good top-dressing after having taken off as much as possible of the surface soil without doing injury to the roots. See also that the drainage is good. For potting they like a compost of good fibrous loam, not too small, leaf-mould and the addition of some bone-meal and cow-manure, with a liberal amount of coarse sand.

Ferns.—Now that these have completed their season's growth and the power of the sun's rays is waning, less shade will be necessary, and this will also make the plants much more suited to room decoration. The plants will take abundance of water, especially on hot days, and plenty of humidity should be maintained by frequently damping between the pots and the floors of the house. A little soot-water, properly diluted, will be found a good stimulant. Ferns in hanging baskets will benefit by being immersed in a pail or tank of water.

Gloxinias.—As the flowering discontinues, the amount of water should be gradually withheld from the plants, so that the drying off of the foliage takes place gradually; and to assist in the maturation the plants may be removed to a more airy position, such as a shelf in quite a cool structure. When thoroughly ripened, turn the pots on their sides and winter in a warm house, or knock out the bulbs and store them in Cocoanut fibre.

The Vegetable Garden.

Potatoes.—The lifting of the main crop will be needing attention, and, in such a season as we have experienced, the sooner this can be accomplished the better. As soon as the haulm is matured I would recommend cutting it off and removing it to the fire as a means of preventing the spreading of the disease. If possible, choose a dry day for lifting the crop. The closest watch should be kept for any tubers that show the slightest trace of disease, and the latter kept apart; also small tubers, the best of which may be selected for seed next year and placed thinly in a cool shed from which frost can be excluded. Where a quantity of edible tubers have to be stored, and there is not sufficient cold-shed accommodation, these are best placed in pits, having the base slightly above the natural level on a good layer of straw, and as

the ridge of tubers is built up, scatter a light dusting of newly-slaked lime between them.

Celery.—The weather has suited this crop remarkably well. The earliest plantings will need further papering or earthing-up, whichever practice is in vogue. Later plantings must be kept free from weeds and bad leaves, side growths removed, and a loose tie of raffia will keep the leaves intact.

Spinach.—Make another sowing of Long Standing or other approved variety for winter and spring supply. So much depends upon the weather as to the ultimate value of this vegetable; but where space permits, make one or two further sowings. Have the seed-bed level and brought down to a fine tilth, and a surface-dressing of soot and wood-ashes will be found of distinct benefit.

Fruits Under Glass.

Late Grapes.—The recent dull weather has necessitated the use of a little fire-heat to assist in the colouring and ripening of late Grapes, and though the weather has been dull, damping of the floors and borders will have been necessary, with as free a ventilation as possible; otherwise the foliage will be very susceptible to red spider. Do not be too severe in thinning the growths except with white Grapes, which need plenty of light to bring up their colour.

Young Vines.—It is highly important that the growth be thoroughly ripened of young canes; these are oftentimes apt to be over-vigorous and want to continue growth. A little warmth in the pipes and abundant ventilation whenever possible by day and night, with slightly drier conditions in the house, will help to obtain the desired results.

The Hardy Fruit Garden.

Cleansing of the Trees.—As the fruits are gathered should be proceeded with, and especially wall trees, which the rains have hardly touched, and the same applies to watering. Trees that have carried good crops ought not to be neglected, but rather be given the benefits of good soakings of farmyard manure, especially trained trees on walls.

The Shrubberies.

Hydrangea paniculata.—This is a good subject for flowering during the end of August and early September, and those who do not possess this plant would do well to note and plant it if a free-flowering subject is wanted at this season. The old inflorescences may be allowed to remain, and the shoots cut back before growth commences next spring. E. BECKETT, V.M.H.

Aldenham House Gardens, Elstree, Herts.

FOR NORTHERN GARDENS.

The Flower Garden.

Propagating.—Cuttings of *Calceolaria amplexicaulis* should be taken now, so that they may be rooted before winter sets in. Short pieces root more readily than long ones, and it contributes considerably to a satisfactory "strike" to never let them flag. Abutilon cuttings also should be taken. These should be placed in a cool stove, in which they root well enough. Fuchsia cuttings, too, should be inserted in boxes and placed in a cold frame, or, better still, in a manure-heated frame. Choose soft tips, which not only root better, but grow better than hard pieces.

Kochia triophylla.—Well-grown plants which are changing colour may be planted in beds of suitable colours. They provide a change for the next six or seven weeks with little trouble. The plants should be turned out of their pots and the balls sunk deeply in the ground, so that the roots can be moistened two or three times weekly.

Single Hollyhocks.—Seeds will be ready to gather on old plants, which are the only ones that have been really satisfactory this year. Sow at once thinly in cutting-boxes and stand them in a moderate heat to ensure rapid germination. With ordinary attention to potting as required, the plants will be large enough to plant out in April or the beginning of May. Double Hollyhocks, both old ones and yearlings, are true autumnal flowers this year. Of hundreds, none will be flowering till about this date.

Pinks.—Mrs. Sinkins and others of the free-growing section may now be lifted and pulled to

pieces, planting them singly where they are to flower next year. Usually at this date the under part of the shoots is alive with young roots, which facilitate their establishment. Sweet Williams may be treated in the same way, especially the double dwarf crimson variety. If beds of the florists' section have not yet been planted, delay doing so no longer.

The Plant-Houses.

Primula obconica.—Some of the more forward plants may be placed in a warm pit to hasten flowering should they be required for decoration in October or November. A slight surface-dressing of manure will deepen the green of the leaves, which in the improved modern section are too handsome to be overlooked. It, moreover, adds depth and brilliancy to the colour of the flowers; but these stand quite three weeks, pink and deep rose being lovely in low vases.

Room Plants.—Now that fires are once again constantly on, dust will be an appreciable foe to the inside man, who usually gives himself much labour trying to wash it off the foliage of such plants as *Aspidistras*, *Aralias* and *India-rubber Plants*, not to mention the finer type of *Dracenas* and such like. Nothing excels a cloth for dusting. If used wet, the moisture should be wrung out of it, and, as it becomes dirty, rinsed in hot water and again wrung. But a dry cloth often used is best.

The Hardy Fruit Garden.

Blackberries.—This year's shoots of the Parsley-leaved variety should be placed out of the way of the fruiting shoots to permit of the fruit being gathered. Any weak shoots that obviously will not be required for another year should be cut clean out. The Japanese Wineberry is ripening, and, where birds abound, it will be essential to protect the bushes with herring-nets.

Raspberries.—These have continued fruiting for a long time, but are now over, and the bearing shoots should be cut out at once, also any weak ones that are not required, slinging up those that remain and not shortening them meanwhile.

Black Currants.—Boskoop Giant has failed so consistently that I have destroyed it, and am now substituting *Victoria*. The plants are quite ready to replace it, and will probably be planted before these notes appear, this fruit being one of the few that can safely be planted early in autumn. Carter's is perhaps as desirable a variety as *Victoria*.

The Vegetable Garden.

Cabbages.—The main batch will be quite ready to plant out in the course of next week. The plants need not be set wider than 12 inches in the rows and the latter 18 inches apart, the extra plants, should a portion be left to grow again after cutting, being drawn when ready. Those who leave the plants standing too long in the seed-bed may rest assured that the loss in earliness is very considerable, as may be proved by planting another batch a fortnight after these.

Scotch Kale.—This hardy vegetable is so useful in late spring when vegetables are scarce that spare ground may be planted closely with the surplus material still in the seed-bed. The plants will grow very little till spring, when a surface-dressing of a stimulating manure will cause them to produce nice tender leaves. The earlier batch will be ready to have some earth drawn up to the stems.

Late Peas.—Should mildew be apparent, dust the plants as completely as possible with flowers of sulphur, which must be renewed from time to time; or they may be sprayed with a fungicide, which, where there are many grown, is a laborious proceeding, and must also be repeated to be effective. If, owing to the continued wet, podding is tardy, the tops of the haulm may be cut off, which will hasten production.

Cauliflowers.—It is the custom of many gardeners to sow *Early London* or *Erfurt* at this season, choosing a spot on a warm border for the seed-bed, and later transplanting the seedlings closely together near to the base of a wall with a south aspect. The plants make practically no growth all the winter, and are again transplanted, when spring gives a new impulse to vegetation. Very fine early Cauliflowers are procured by setting five plants under an ordinary four-square hand-glass, the present time being also suitable to sow seeds for that purpose.

R. P. BROTHERSTON.

Tynninghame, Prestonkirk, N.B.

NEW AND RARE PLANTS.

Cofoneaster divaricata.—This is a recent introduction from China of irregular, sub-erect habit of growth. The species bears the impress of freedom and vigour, and for bold grouping should prove most effective. The oval-shaped fruits are coloured a rich scarlet. From the Hon. Vicary Gibbs, Aldenham House, Elstree. First-class certificate.

Each of the following received an award of merit :
Dahlia Princess Louise (Collarette).—The florets are coloured an intense crimson; the small inner florets are white. The form is excellent. From Messrs. Dobbie and Co., Edinburgh.

Dahlia Antwerpia (Collarette).—A good scarlet with yellow base and yellow disc florets. From Mr. J. B. Riding, Chingford.

Dahlia Edith Carter (Cactus).—A most attractive flower from any point of view. The flower gives the impression of a rich golden yellow whose florets to half their depth had been dipped in a reddish crimson colour. It is very showy. From Mr. H. Shoemith, Woking.

Dahlia Pegasus (Cactus).—A fancy variety whose rosy-coloured florets are touched with crimson. From Messrs. J. Stredwick and Sons, St. Leonards.

Dahlia Leopold (Single).—A fine rich crimson with golden disc.

Dahlia Marion (Single).—Rose and fawn, suffused yellow, and slight crimson zone at the base of the florets.

Dahlia Irene (Pompon).—The colour is rosy lilac, the form a model of its kind. These three were exhibited by Messrs. J. Cheal and Sons, Crawley.

The whole of the Dahlias above-named, having been adjudicated upon by a joint committee of the National Dahlia Society and the Royal Horticultural Society, carry the first-class certificate of the former and the award of merit of the latter.

Odontoglossum Helene.—An unusually dark-flowered variety of good form. Sepals and petals of reddish chocolate, suffused and veined with white. The lip is also white.

Lælio-Cattleya amabilis Borlases Variety.—The white sepals are long and narrow, the petals broad, white suffused delicate pink, lip crimson-purple, with yellow in the tube. A handsome variety.

Odontioda Euterpe.—A variety of remarkable beauty, distinction and rich colouring. Viewing the flower from behind and looking towards the light, a rich reddish wine colour is seen, while from the front a clouded vinous crimson is presented to view. The lip is of reddish tone, reticulated with white and blotched lightly with yellow. These Orchid novelties were exhibited by Mr. E. H. Davidson, Borlases, Twyford.

Angræcum o'brienianum.—A pretty, pure white flowered variety. Shown by J. S. Bergheim, Esq., Belsize Court, Hampstead.

NEW FRUITS.

Melon John Murray.—This variety is characterised by its exceptionally deep scarlet flesh, and, having been on trial at Wisley, was given the high award of a first-class certificate. From Messrs. William Rowlands and Co., Liverpool.

Apple Padnal Seedling.—An excellent cooking Apple with a certain leaning towards Warner's King, and possibly also to Potts' Seedling. Fruits

and fruiting branches were on view, an award of merit being granted on the recommendation of a sub-committee who had inspected the stock. A remarkable cropper and of good size. Exhibited by Mr. R. Roberts, Padnal Hall, Chadwell Heath.

All the foregoing plants and fruits were shown at the Royal Horticultural Society's exhibition on the 27th ult., when the awards were made.

ANSWERS TO CORRESPONDENTS.

RULES FOR CORRESPONDENTS.

QUESTIONS AND ANSWERS.—The Editor intends to make THE GARDEN helpful to all readers who desire assistance, no matter what the branch of gardening may be, and with that object will make a special feature of the "Answers to Correspondents" columns. All communications should be clearly and concisely written on one side of the paper only, and addressed to the EDITOR OF THE GARDEN, 20, Tavistock Street, Covent Garden, London, W.C. The name and address of the sender are required in addition to any designation he may desire to be used in the paper. When more than one query is sent, each should be on a separate piece of paper. Plants for naming should be clearly numbered and securely packed in damp grass or moss, not cotton-wool, and flowering shoots, where possible, should be sent. It is useless to send small scraps that are not characteristic of the plant. Letters on business should be sent to the PUBLISHER.

FLOWER GARDEN.

SEEDLING BORDER CARNATIONS (C. R. A.).—The colour defects to which you refer should be regarded in the light of sports, and they may or may not appear again. To some extent this reappearing or otherwise may be governed by proportion; that is to say, if an entire flower is changed, then the shoots attached thereto may, and usually do, reproduce the change. When, however, a flower is only partly transformed, anything may happen. Hence you had best consult your own desires. Calyx splitting is a fault rather than a weakness, and may be due to a badly-shaped calyx, to abnormally full-petaled flowers, or to excessive disbudbing where this is done. If the calyx is of the Pear-shaped order—big at the top and narrow at the bottom—throw the plant away; it will never be any good. If long, and the present splitting is merely a slight side burst, it may have resulted from the season or from excessive vigour. In youth, seedlings put on much of this, and some of it is lost in future years. Usually, however, only the moderately long, cylindrically-formed calyces are those which remain intact. Perfect calyces are as rare as perfect flowers, and such as these rarely reach 5 per cent. of the seedlings raised by the specialists.

TIGER LILIES AND OTHER QUESTIONS (C. V. B.).—The leaf disease is doubtless that which attacks many kinds, and for which the ever-changing climatic conditions are in some measure responsible. By spraying with sulphide of potassium (half an ounce to two gallons of rain-water) once a fortnight in the early stages of growth, or, say, from when the growth is 1 foot high till the stem is fully grown, it might be kept in check, or prevented from doing any great harm. It would help matters if you collected the diseased parts and burned them. You might certainly transplant the bulbs when flowering is over, and fresh soil and a fresh site might have a beneficial effect. Now that September is here, you can transplant the Meadow-sweet and other things. We must, however, warn you as to the weed-like character of such things as Willow-herb, which is pretty enough in woodland places, though hardly a plant for the garden. You are a little impatient as to the Roses, which at least require to become established and make shoots in their new home before they are capable of giving a good account of themselves. The big rods now forming should be encouraged and retained, as upon the maturing of these a good flowering another year depends. All small, twiggy growths at the base might now be cut away.

TREES AND SHRUBS.

ESCALLONIA HYBRID (A. M., Ambleside).—The specimen of Escallonia sent for examination appears to be, as you suggest, a hybrid between *E. philippiana* and *E. macrantha*. It has much of the habit of another hybrid, *E. langleyensis*, but differs from that by reason of its pale-coloured flowers. We advise you to grow the plant in a good position for a year or two to test it; then if it appears to keep quite distinct and is good in habit and flowering qualities, it might be named and put into general cultivation. We do not know of a kind just like it.

SHADE TREE FOR LAWN (G. G.).—From what you tell us of your lawn, we should say that you have not room for another tree, especially one which, to be of much use, must be a fairly large-growing one. The suggestion we venture to make is that the Apple tree you mention should be removed, and a Weeping Ash or Weeping Wych Elm placed in the position it now occupies. It is not a good

plan to overcrowd a lawn with trees, for a great deal of the pleasure attached to a garden is derived from a good stretch of lawn; moreover, by crowding the grass with trees, the turf becomes weak, and in winter-time a considerable quantity of moss appears.

THE GREENHOUSE.

NORFOLK ISLAND PINE (R. S. M.).—It is quite possible to root the top of your plant of *Arancaria excelsa*. If you have a close and warm propagating-case, the top may be removed bodily and be inserted as a cutting; but if you have to rely on an open house or room, it would be better to do as you suggest and moss the stem round. To do this make an incision in the stem through a joint in an upward direction for 1½ inches or so. Insert a small piece of wood to keep the slit open, then cover the wound with a good bandage of moss and sand, binding it on so that there is no fear of its slipping. Keep the moss moist until roots appear through it. When well rooted remove the head and place it in a small pot in moist soil, but do not give any water for a few days. If you prefer to place a pot round the moss after the roots show, you may do so, but you will probably have a difficulty in dividing the pot in the first instance. The best way to do this is to mark the pot with a pencil, then file a ridge round. After this, a gentle tap with a hammer will break it in the required place. It may then be placed in position with the aid of stakes and string.

AURICULAS AND THE WOOLLY APHIS (J. E.).—The woolly aphis is very troublesome to growers of Auriculas, and the late Mr. James Douglas, who was unsurpassed as a cultivator of these beautiful flowers, used to advise having a pepper-box of Tobacco powder and freely sprinkling the roots, from which as much as possible of the soil had been removed. As this, however, proved ineffectual in your case, the advice of another successful cultivator may be of service. He says the best remedy against the aphis is soft soap dissolved in water. All the soil must be removed, and the roots immersed in the solution. Then they should be laid upon the palm of the left hand and well scrubbed with a soft-haired brush. Should the pests gather round the neck of the plant at a time when it would be injurious to remove the soil, this soap and water may be applied with a small brush to the infected parts. We advise you to try this on two or three of your worst plants first, and note the results before proceeding further. We question if mustard would do any good. If the old pots are to be used, it is most essential that they are thoroughly scalded beforehand, as the eggs of the pest may be adhering thereto. The soil, too, had better be sterilised.

ROSE GARDEN.

NAMES OF ROSES (C. F. F.).—No Rose-grower of any repute would have sent you Roses so glaringly inaccurate as those you send us. The white one is White Dorothy Perkins, and the two reds are Crimson Rambler and Flower of Fairfield.

ROSES FOR LAWN PLOT (Amateur, Glasgow).—You would do well to plant a few pillars in this plot, as they would tend to relieve it of flatness. Moreover, some Roses, such as Hugh Dickson, bloom more freely when trained as pillars. A few good sorts would be Hugh Dickson; J. P. Clark, Grass an Teplitz, Zepherin Drouhin, Lina Schmidt-Michel, Sarah Bernhard, Rosette de la Legion d'Honneur, Gustave Rezis, Avoca, Lady Waterlow, Conrad F. Meyer and Nova Zembla. Some good decorative sorts to grow as bushes would be Mme. Abel Chatenay, Mme. Ravary, Caroline Testout, Edu Meyer, Harry Kirk, Antoine Rivoire, General Maearthur, Gustav Grunerwald, Prince de Bulgarie, Lady Ashton, Mme. Jules Grolez, Joseph Hill, Mme. Leon Pain, Pharisæer, Countess of Derby, Duchess of Wellington, Mrs. Alfred Tate, Killarney, Lady Battersea, James Coey, Laurent Carle, Mrs. Aaron Ward, Mrs. A. R. Waddell and Viscountess Folkestone.

MISCELLANEOUS.

WEEDS IN POND (C. J. S.).—Copper sulphate may be used at the rate of 2½ oz. to 10,000 gallons of water for killing weeds in ponds, although it is often used in slightly lower proportions; 2oz. to 10,000 gallons has been found satisfactory when the weed has not been very thick. As an instance of how the amount may be varied, some authorities recommend using one part of copper sulphate to from 750,000 to 1,000,000 parts of water. We have known the above proportions used for several years without ill-effect.

TO CLEAR THE SCUM OFF THE SURFACE OF A POND (Perplexed).—If, as you say, the scum on your pond appears to be of a dusty character, we imagine that the water is stagnant. By causing it to be disturbed, such as would be the case by letting the water run through rather rapidly, the scum ought to be cleared away. We presume that the water is constantly flowing into and out of the pond. In the event of the scum being of a vegetable nature, you cannot do better than introduce copper sulphate at the rate of 2oz. to 2½oz. to 10,000 gallons of water. Tie the copper sulphate in a canvas bag and draw it through the water till dissolved.

NAMES OF FRUIT.—T. S.—1, Warner's King; 2, Round Winter Nonsuch; 3, Adam's Pearmain; 4 and 11, Tower of Glamis; 5, Ecklinville Seedling; 6, Old Hawthornden; 7, Gold Medal; 8, Annie Elizabeth; 9, Fearn's Pippin; 10, Beauty of Kent; 12, Mank's Codlin; 13, Worcester Pearmain; 14, Striped Beaufin; 15, Yorkshire Beauty; 16 and 20, Pickering's Seedling; 17 and 21, Blenheim Orange; 18, Mère du Ménage; 19, King of the Pippins; 22 and 23, Lord Suffield.—T. H. O. Pease.—

1, Koswick Collin; 2, Devonshire Quarrenden; 3, Beauty of Bath; 4, Lord Grosvenor; 5, Flanders Pippin; 6, Cat's-head; 7, Mère du Ménage.—E. Martin.—1, Margit; 2, White Must.

NAMES OF PLANTS.—M. F. F.—Phloxes: Scarlet and white, Flambeau; mauve and white, Eugénie Danzanvillers; deep mauve, Le Mahdi; pink and white, Elizabeth Campbell; pink with red centre, Selma. The other plant is *Lupinus polyphyllus roseus*. In future, when sending plants for naming, please attach numbers to the specimens.—Farmer.—Lychuis chalcidonica.—H. S. C.—Rose Francois Foucard.—P. H.—1, *Linaria pilosa*; 2, *Anthriscus deltoideus* variety; 3, *Sedum* species, send in flower; 4, *Sedum asiaticum*; 5, *Spirea Aruncus* (Goat's Beard); 6, *Thalictrum minus*; 7, send in flower; 8, *Pulmonaria officinalis* (common Lungwort); 9, *Veronica virginica rosea*.—A. Midgley.—Apparently *Polygonum viviparum* (Alpine Bi-stort).—John Turner.—1, *Populus canescens* (Gray Poplar); 2, *Esculus flava* (Sweet Buckeye).—Woodman.—1, *Eucryphia pinnata*; 2, *Lythrum Salicaria* (Loosestrife).

SOCIETIES.

ROYAL HORTICULTURAL SOCIETY.

DESPITE the abnormal wetness of the season, a display of much excellence was brought together on the 27th ult. Hardy flowers were, indeed, finer than could have been expected, the Dahlias, if not as yet in characteristic beauty, being of much merit. The outstanding features of the meeting, however, were the collections of pot-grown fruit trees. Here, indeed, was food for the eye and the mind, and, anon, it may be for the body also. To the gardener and visitor such exhibits are an education, and are welcomed accordingly. They were, indeed, magnificent of their kind.

FLORAL COMMITTEE.

Present: H. B. May, Esq. (chairman), and Messrs. C. T. Drury, J. Green, George Gordon, W. J. Pean, G. Reuthe, W. Bain, John Dickson, Charles Dixon, H. J. Jones, J. T. Bennett-Poe, Charles E. Pearson, W. P. Thomson, G. Paul, W. J. James, E. A. Borles, R. C. Notcutt, F. Herbert Chapman, C. Blick and E. H. Jenkins.

Messrs. James Veitch and Sons, Limited, Chelsea, displayed a highly-interesting table of greenhouse flowering plants, inclusive of distinctive groups of Streptocarpus in white, rose, blue, pink and violet shades in plants seven months old from seeds; the pretty *Browallia viscosa*, flowering trails of *Passiflora princeps* and *Schubertia grandiflora* (scarlet and white flowered respectively), a delightful colony of the hybrid *Javanico-jasminiflora* *Rhododendron*, *Browallia speciosa* major, a handsome group of *Cannas* in rich and varied colouring, together with an interesting lot of *Begonias*, of which E. Froebelii incomparabilis, with crimson scarlet flowers and woolly petioles and buds, was very striking. This low-habited, free-flowering plant is among the most ornamental we have seen. *B. Lucerna*, with drooping tresses of pink flowers and white-freckled leaves, was also in good form.

A small group of Perpetual-flowering Carnations came from Messrs. Harbutt, Humberstone Gate, Leicester, Mikado and May Day being among the varieties shown.

Messrs. Piper, Bayswater and Barnes, arranged amid stately Palms a fine lot of *Lilium speciosum cruentum* and other richly-coloured varieties, the plants well grown and flowered. *Asparagus Sprengeri* constituted a good margin. Some nice examples of *Wahlenbergia vincaeflora* also came from this firm.

The Misses Hopkins, Shapperton-on-Thames, had a pretty rockwork exhibit, arranging *Sedums*, *Campanulas*, *Potentillas*, *Linarias* and *Viola* species effectively among the rocks.

Mr. Amos Perry, Enfield, had a fine display of Delphiniums, the product of spring-planted stock, which as a succession to the main flowering is of much value. Mrs. Creighton, purple; Lizzie, sky blue, white eye; King of Delphiniums, an ever-popular variety; Duke of Comancha, dark blue single, with conspicuous white eye; Perfection, rosy lavender, with outer petals pale blue, a very fine; and Amos Perry, rosy mauve and dark blue, a most showy variety, were among the best in a really grand lot. Persimmon, sky blue, white eye, is also a notable single-flowered sort.

Messrs. William Fells and Son, Hitchin, arranged a table of hardy plants, such as alpinas in pots, cut herbaceous subjects of the bolder types, together with a small sandstone rockery whereon were planted *Campanulas*, *Linarias*, *Lysimachia Henryi*, *Dianthi* and the like, while at each end was seen a collection of *Violas* and *Pansies* set in tubes.

Mr. James Box, Lindfield, Sussex, had a superb and showy lot of hardy cut flowers, the herbaceous Phloxes being exceptionally fine. Widar, mauve blue and white; Gloire du Mare, red fish purple; Iris, deep violet; Le Mahdi, deep mauve; General Van Heutz, salmony scarlet, white eye, very fine; and Selma, pink, were some of the best in a superb lot. *Gladioli*, herbaceous *Lobelias*, *Kniphofias* and *Artemisia lactiflora* were all well displayed.

Messrs. William Cutbush and Sons, Highgate, N., had a capital exhibit of hardy plants in conjunction with Water Lilies and other plants. The *Pentstemons* were particularly fine and made a big show. *Gladiolus Hollandia* (a fine bluish pink), with masses of *Kniphofias*, *Calliolas*, *Phloxes* and *Hedoniums* were all good and showy. *Polygonum cymosum album*, *Stenanthium robustum*, *Crimum Powellii* and *C. P. album* were other important items in a fine group.

Mr. W. A. Gwillim, Sidcup, Kent, had a superb lot of *Begonia* flowers on boards, and splendid pot-grown examples to boot, the magnificent double flowers of the

latter being of unusual size and fine form. A collection of herbaceous plants was also arranged by this firm.

Messrs. Dobbie and Co., Edinburgh, showed a particularly fine lot of the Collarette Dahlias, some five dozen stands and vases being arranged with admirable taste and skill. Among the more striking were Queen Bess, reddish mahogany and gold; Meteor, crimson and gold; Exposition de Lyon, ruby red and creamy inner florets; Balmoral, reddish violet and white; Princess Louise, crimson guard petals, inner ones primrose; Frogmore, scarlet and gold; Antwerpia, crimson-scarlet and yellow; and Mme. Poirier, violet blue, with white inner florets. These made a very showy group.

Mr. L. R. Russell, Richmond, arranged what was virtually an avenue of *Celosias* to an accompaniment of *Begonias* of the Rex section, the latter being exceptionally well-grown specimens. The *Celosias* were pot-grown examples, and were in groups of crimson, ruby, yellow and pale orange, the whole making a showy display. A background of variegated *Eulalia* played its part uncommonly well.

Mr. G. Reuthe, Keston, Kent, had another of his varied and interesting groups of alpinas and shrubs, which never fail to attract. *Erica vulgaris* Foxii (quite a miniature), *E. v. flore pleno* (a charming plant), *Linarias* in variety and *L. alpina rosea* were most charming. *Silene Elizabethae*, *Tunica Saxifraga fl.-pl.*, *Viola bosniaca*, *Crimum Powellii* and *Desfontainia spissa* were among the more attractive on this occasion. Some good pans of autumn Cyclamen were also noted.

Mr. Ernest Dixon, Putney and Roehampton, had a small group of showy herbaceous things, such as Phloxes, *Pentstemons*, *Lupinus*, *Delphiniums* and the like. *Viola cornuta atropurpurea* was also well shown.

Clerodendron carulea is a pretty and uncommon blue-flowered climbing species exhibited by Sir Trevor Lawrence, Bart., Dorking, the plant also being known, we believe, as *C. ugandense*. It is as charming as it is interesting.

Mr. J. Hindson, gardener to Mr. Leopold de Rothschild, Gunnersbury House, showed in tubs some superb examples of blue-flowered Water Lilies, *Nymphaea giganta* variety *hudsoniana* being magnificent. The giant deep lavender blue flowers were 8 inches in diameter. *N. pulcherrima* and *N. stellata* Berlin variety were both of great beauty and merit, if lacking the fine colour and handsome proportions of that first-named.

Mr. Reginald R. Cory, Duffryn, Cardiff, exhibited Dahlias of several sections, Pompon, Collarette, *Pæony* and others. The flowers were well displayed in stands.

The Hon. Vicary Gibbs, Aldenham House, Elstree (gardener, Mr. Beckett), had a remarkable exhibit of cut *Buddleia* sprays in some dozen or more sorts. *B. variabilis magnifica*, *B. v. rosea*, *B. v. gigantea*, *B. v. Delight* and *B. nivea* were the more distinct.

Messrs. J. Cheal and Sons, Crawley, had a charming lot of Dahlias, particularly of single-flowered varieties, Brilliant, Glencoe, Rosebank Scarlet, Betty, Mrs. Miller, Elmira and Kitty being noted in a good lot. *Pæony* and *Cactus* flowered sorts were also well shown.

Messrs. H. Cannell and Sons, Swanley, had a large variety of *Cactus*, decorative and other Dahlias, The Bride, Harold Pearman (yellow), Mrs. Douglas Flemming (white) and J. H. Jackson being all good *Cactus* varieties. In the giant single-flowered class, Cannell's Favourite (crimson and gold) and White Cloud (very handsome and pure) were the best. Collarette Dahlias and a handsome lot of double *Begonias* were also shown. A dozen flowering plants of *Crassula falcata* contributed to a fine display.

Messrs. H. B. May and Sons, Edmonton, exhibited Ferns, together with *Ixoras* and the brilliantly-coloured *Croton edmontoniense*, *Nephrolepis Marshalli* compacta was in excellent form.

Messrs. G. Bunyard and Co., Maidstone, had a very showy exhibit of hardy plants, though chiefly of *Delphiniums*, *Pentstemons*, hardy *Fuchsias*, *Scabiosa* and the like. *Crimum Powellii* and *C. P. intermedia* were also noted, while King of *Delphiniums* and the blue, white-eyed *D. Nerissa* were both seen in nice groups. The many varieties of the Japanese *Anemone* were all well shown.

Messrs. William Wells and Co., Merstham, brought a capital display of Phloxes, such as Le Mahdi, King Edward (reddish), Rose Queen and Arthur Rane (pink) being very fine. *Veronica subsessilis* and *Senecio chlororum* were both in excellent condition.

FRUIT AND VEGETABLE COMMITTEE.

Present: G. Bunyard, Esq. (chairman), and Messrs. A. H. Pearson, W. Poynter, John Harrison, Owen Thomas, James Vert, Joseph Davis, George Kelf, A. R. Allan, W. E. Humphreys, J. Willard, E. Beckett, G. Woodward and J. Cheal.

From Messrs. James Veitch and Sons, Limited, Chelsea, came a magnificent collection of pot-grown fruit trees, Pears, Apples, Plums and the like, to the extent of some one hundred and seventeen varieties in trained, standard and pyramidal examples. For such exhibits as these, educational as they are in the highest degree, no praise is too great; hence we extend our need of it without reserve. From the cultural standpoint alone such an exhibit, varied and complete as it undoubtedly was, merited high praise by reason of the perfection attained, while from the standpoints of extent and comprehensiveness such magnificent collections are only possible to a few. In so representative a group we can only hope to give a selection. Of dessert Apples, Duchess Favourite, Charles Ross, Christmas Pearmain, Langley Pippin, Worcester Pearmain and James Grieve were the best; while of culinary Apples, Bismarck, Alexander (very handsome-looking), Cox's Pomona, Lane's Prince Albert, Warner's King, Stirling Castle and Peasgood's Nonsuch claimed attention. Of Pears, Bourne Rose, Bourne d'Amaldis, Clapp's Favourite, Dr. Jules Guyot, Louis Bonne of Jersey and Pitmaston

Duchess were of special merit; while of Plums we noted such excellent sorts as Coe's Golden Drop, Bullace The Langley, Jefferson, Reine Claude du Comte Hathem, Grand Duke and Lawson's Golden Gage. The comparatively small pots and trees, loaded with fine fruits, were a great tribute to the cultural skill demonstrated as a whole. This unique exhibit was deservedly awarded the Hogg gold medal, the top rung of the fruit-tree ladder.

Messrs. G. Bunyard and Co., Maidstone, also displayed a remarkable and varied exhibit of orchard-house-grown fruit trees in pots, in conjunction with hardy fruits of a varied character, into which a dozen varieties of Cob Nuts and Filberts and a similar lot of ornamental Crabs entered. The pot-grown fruit trees, however, were those which attracted most attention, and here we saw superbly-grown examples of Plum, Pear and Apple as good as could be imagined or desired. Apple trees loaded with Allington Pippin were superbly finished, white such as Wealthy, Gascoyne's Scarlet (of rich colouring), Peasgood's Nonsuch, Cox's Orange Pippin, Baumann's Red Winter Reinette and Emperor Alexander were in every way excellent. Small trees of the good culinary Apple Rev. W. Wilks displayed the free-cropping attributes to advantage. Pears were also in good variety, while Plums were represented by such as Monarch, Coe's Golden Drop, President and others. In addition to these, a large collection of gathered fruits was shown of rare quality. A gold medal was deservedly awarded for this collection.

Mr. G. Kelf, gardener to the Hon. Mrs. Merry, Danesbury Park, Welwyn, Herts, brought a collection of about eighteen varieties of Plums in boxes, grown in the open air. The collection embraced all the best-known varieties, as Kirke's Monarch, President, Coe's Golden Drop, Jefferson, Poad's Seedling and others.

An assortment of Runner Beans and culinary Peas was contributed by the Rev. Chalmers Hunt, Hitchin, while from the Comtesse of Ilchester, Holland House, came some eighteen or so varieties of ornamental Crabs.

Messrs. Stuart Low and Co., Enfield, staged a collection of pot-grown Figs, Apples and Grapes in capital condition, while Carrots of a model type, without spot or bluish, in both long and short horn varieties, came from Mr. Z. Gray, Sanday.

Messrs. Cannell and Sons, Swanley, had large representative collections of gathered fruits, Apples, Pears and Plums being well shown. Of the last-named we noted such as Washington, Jefferson, Goliath, Kirke's Blue, Rivers' Late Orange, Cox's Euphor and Prince Englebert, all in capital form.

ORCHID COMMITTEE.

Present: J. Gurney Fowler, Esq. (chairman), Sir Jeremiah Colman, Sir Harry J. Veitch, and Messrs. J. O'Brien, W. Bolton, Gurney Wilson, de E. Crawshaw, Arthur Dye, H. G. Alexander, J. E. Shill, W. H. Thatcher, Walter Cobb, A. H. McBean, T. Armstrong, F. J. Hanbury, Stuart H. Low and R. A. Rolfe.

Messrs. Sander, St. Albans, had a very beautiful lot of *Cattleyas* and *Laelio-Cattleyas* in variety, also such good things as *Burlingtonia fragrans*, *Cypripedium Rossettii*, *Disa grandiflora*, *Cattleya Stauvior* alba (very pure and good) and the strange-looking *Catasetum maculatum*. *Laelio-Cattleya* Walter Gott was also noted among distinct things.

Mr. H. Pitt, Rosslyn, Stamford Hill, had in a most interesting lot *Cattleya Source d'Or* (choice and distinct in colour), *Odontodia Charlesworthii*, *Epidendrum Wallisii*, *Catasetum fimbriatum* (very quaint-looking) and the lovely white, yellow-tipped *Laelio-Cattleya Delicata*.

Messrs. Charlesworth and Co., Hayward's Heath, included in a small yet choice lot *Aerides Lawrenceae* var. *sanderiana*, *Cattleya gaskelliana*, *Houlletia Wallisii* and *Lelia macrotaehya*. *Polycyema muscifera* was also remarkable for its fairy-like bronzy flowers and elegant grace.

Mr. E. H. Davidson, Borlases, Twyford, had a delightful lot of *Laelio-Cattleyas*, *Cattleyas*, *Odontodias* and *Odontoglossums* in pleasing variety. This exhibitor secured three awards of merit for his leading novelties, *Odontodia Enterpe* in this collection was singularly rich in colour.

Messrs. J. A. and A. McBean, Cocksbridge, Sussex, had a rather handsome plant in flower of *Vanda sanderiana*, which, with richly-coloured *Odontodias* and *Odontoglossums*, were very attractive.

Messrs. Stuart Low and Co., Enfield, had a fine example of *Laelia crispata*, together with *Oncidium varicosum* Rogersii, *Odontodias* and others. Some good examples of *Dendrobium Phalenopsis* were also noted.

ABERDEEN HORTICULTURAL SOCIETY'S SHOW.

THE great three days' show of this society took place in the Duthie Park, Aberdeen, on August 22, 23 and 24, and was one of the best yet held, although the lateeness of the season has told on certain exhibits. The entries were practically the same as in former years, and the exhibits did full credit to such an important horticultural centre as Aberdeen. It is impossible in the space available to do justice to the show, but it may be said that pot plants were very fine in every way; that cut flowers were, as a rule, very good, Roses and Sweet Peas being perhaps the strongest classes. Fruit was good, and in some classes of superb quality, while vegetables were an outstanding section. In the professional classes Mr. W. Dick, Mr. J. Elder, Mr. A. Brebner, Mr. J. W. Brechin, Mr. J. Petrie, Mr. J. Burnett, Mr. A. Gillespie and Mr. J. Anderson were the chief winners with pot plants. For cut flowers Mr. A. Brebner led for eighteen Rose blooms, distinct; Mr. J. Burnett for twelve; Mr. J. Petrie for six bunches of decorative; and Mr. W. Lockhart for twelve Teas or Noisettes. Mr. A. Douglas was first for herbaceous plants.

EDITORIAL NOTICES.

Every department of horticulture is represented in **THE GARDEN**, and the Editor invites readers to send in questions relating to matters upon which they wish expert advice.

The Editor welcomes photographs, articles and notes, but he will not be responsible for their safe return. All reasonable care, however, will be taken, and where stamps are enclosed, he will endeavour to return non-accepted contributions.

As regards photographs, if payment be desired, the Editor asks that the price required for reproduction be plainly stated. It must be distinctly understood that only the actual photographer or owner of the copyright will be treated with.

The Editor will not be responsible for the return of artistic or literary contributions which he may not be able to use, and the receipt of a proof must not be taken as evidence that an article is accepted. Publication in **THE GARDEN** will alone be recognised as acceptance.

Offices: 20, Tavistock Street, Covent Garden, W.C.

NOTES OF THE WEEK.

Tulips and German Irises.—Now that the hulk-planting season is with us, it may be useful to recall a charming combination of German Irises and Tulips that was noticed last May. This was a hold grouping of the common blue German or Flag Iris, thinly interspersed with the lavender-coloured Tulip the Rev. H. Ewbank. Those who possess groups of the Iris in question should procure some bulbs of this Tulip during the next few weeks and plant them between the Irises.

White Phloxes and Gladioli.—Since writing the note about the white Phlox Mrs. E. H. Jenkins in our issue for last week, we have seen a large bed filled with it and the scarlet *Gladiolus brenchleyensis*, in the proportion of two parts Phlox and one part *Gladiolus*. This is a simple effect that might be carried out in many gardens, but room should be left, when planting the Phloxes in autumn or winter, for the *Gladiolus* corms, which would be planted at the end of March or early in April.

Gladioli and Gypsophila.—One of the most effective hedding arrangements we have seen this month is that of late-flowering *Gladioli* over a groundwork of *Gypsophila paniculata*. The *Gypsophila* is kept to a height not exceeding 18 inches, and the tall, handsome spikes of the *Gladioli*, with sword-like foliage arising from a cloud of *Gypsophila*, is most effective. The *Gladioli* are seen to the best advantage if each bed is kept to one colour. Dark crimson and deep pink shades lend themselves admirably to this arrangement.

Japanese Windflowers.—When thoughtfully planted, Japanese Windflowers or Anemones may be used with good effect for an early autumn display. If grown under the shade of trees and fringed with the little autumn-flowering *Cyclamen*, *C. europæum* and *C. hederæfolium*, the association of colour at this season, when the plants all flower together, is exceedingly beautiful. *Allium Huteri*, a little-known species with purple flowers and about eighteen inches high, is well adapted as a groundwork for Japanese Anemones, and produces a fine colour effect at this time of the year.

Paved Lavender Walks.—Lavender walks were pleasing features of gardens in hygone days, and it is gratifying to note that they are being revived in many places. A paved walk lends an old-world appearance quite in keeping with this phase of gardening, and if Harebells or dwarf blue *Campanulas* can be induced to grow between the paving-stones, the effect in late summer is most pleasing. The blue *Campanulas*, the Lavender flowers and its grey foliage all enter into perfect harmony of colour. The silvery blue variety of

Campanula pusilla known as Miss Willmott is specially adapted to this purpose.

A Useful Hardy Heath.—*Erica vulgaris* Foxii is one of the dwarfiest, daintiest and most desirable of the hardy Heaths now in flower, and a delightful plant in every way. Its rounded, cushion-like tufts are particularly dwarf and compact, the whole plant being studded with pinkish flowers on short, erect stems. The plant is so eminently fitted to the cool and sheltered places of the rock garden that those desiring the best of everything should make a note of this elegant and pretty variety.

Sternbergia lutea.—One of the signs of the oncoming autumn is the appearing of the flowers of this small group of bulbous plants, the best of which, perhaps, for garden purposes is that known as *S. l. angustifolia*, and which is characterised by narrower leaves of a rather dark and shining green. The rich yellow flowers of both are a great attraction in the garden at this season, and where the plants succeed they deserve much encouragement. The species are impatient of removal, and should be left alone to become established. They grow best in sandy loam of considerable depth.

Torch Lily, or Flame Flower.—Of early autumn flowers few are more striking than the Torch Lily, or Flame Flower. It is seen to the best advantage when planted in bold clumps by the water-side or in large irregular beds in the pleasure grounds. The handsome spikes in warm orange red tones of colour have earned for this plant the popular title of Red-hot Poker. The species *Kniphofia aloides*, or *Tritoma Uvaria* as it is still called in many gardens, is perhaps the oldest, and certainly one of the best of the family. In hard winters many kinds have perished, but this may be arrested by a covering of dry leaves or ashes in late autumn.

A Wonderful Potato Crop.—Considerable interest has been aroused in the Croydon district recently by an extraordinary crop of Potatoes. It seems that last spring the St. Barnabas, Sutton and District Horticultural Society purchased fifty-one 1lb. bags of seed Potatoes, each containing nine tubers, and distributed them among the members. Four prizes were offered for the heaviest yield and four for the best quality. The happy winner of the first prizes for both weight and quality was Mr. C. F. Clark, The Gardens, Banstead Grange, Banstead, Surrey. His crop turned the scale at 231½lb., made up of 29lb. 2½oz. of ware size, 9lb. 7oz. of seed size, and 2lb. 14½oz. of chats or small ones. The variety was a special selection of The Colleen. It would be interesting to know how frequently the stems of the plants were layered during their growth.

CORRESPONDENCE.

(The Editor is not responsible for the opinions expressed by correspondents.)

Diseased Sweet Peas.—The diseased Sweet Peas mentioned in your issue last week, page 445, as sent for the inspection of the Royal Horticultural Society's scientific committee, were grown in a private garden, and not at the Shelley Sweet Pea Farm, where no streak has appeared.—T. H. DIPNALL.

Tunica olympica.—In the Olympian Rock Tunica we have a counterpart of the better-known T. Saxifraga, but with white flowers. It is as free-growing, as hardy and as pretty in its graceful habit. For a rockery the Olympian Tunica deserves consideration, either alone or as a companion to T. Saxifraga. A dryish soil and a sunny place are desirable for these pleasing flowers.—S. ARNOTT.

Calceolaria amplexicaulis.—This handsome but somewhat neglected plant, with its flowers of a beautiful soft lemon yellow, is, without doubt, the most attractive of the whole genus that is used for bedding purposes. A large bed filled with this and intermixed with the beautiful blue *Salvia patens* gives a very pleasing effect during the summer. Like all other Calceolarias, it requires a little shade and a good loamy soil enriched with well-decayed manure. Cuttings should be taken during September or early in October and put in boxes, but they require more warmth during the winter than the ordinary bedding-out Calceolaria.—F. G. P.

Dwarf French Bean Sutton's Green Gem.—It would be well if the characteristics of this Haricot Bean were better known. Here we always sow a good breadth of it, and guests who have not previously tried it are invariably charmed with it. The seeds are pale green in colour, and, when properly cooked and served, the dish presents a most appetising appearance. When stored the seeds do not, as a rule, lose their green colour, and they make a tempting and agreeable adjunct to our meals throughout the winter. The plant is a prolific bearer, giving a good crop here in both wet and dry seasons.—F. HERBERT CHAPMAN, *Rotherside Gardens, Rye.*

Cordon Gooseberries.—There are many gardens where cordon-trained trees of the Gooseberry might be introduced with great advantage. Planted at the foot of walls between other trees on a trellis consisting of wood or wire, or even trained to stakes, they are most useful, and much waste land can be profitably utilised by their introduction. Single, double or treble cordons may be used, according to the space to be covered. I will not enter into details of cultivation here; this brief note is simply to call the attention of gardeners to the value of cordon Gooseberries for planting on any vacant wall, fence or trellis, no matter whether the site is north, east, south or west.

Planting Conifers.—The present month is considered by several experts to be a good time for the planting of many coniferous subjects. After the heavy rainfall small conifers will be moist at the roots, and will not be liable to suffer from drought. Unfortunately, however, the temperature of the soil is very low, especially in low-lying, wet localities, and it may not be advisable to plant choice subjects unless the land is well drained, either naturally or otherwise. Under these circumstances it would be better to defer the planting until spring. Where the conditions are favourable,

planting may be done now with every prospect of success. With very small plants the risk of failure is reduced to a minimum.—COLIN RUSE, *Lambay Island, Rush, County Dublin.*

Rose Shades for Wet Weather.—Most rosarians have been troubled with hundreds of spoilt blooms owing to the continuous wet weather prevailing. Those who have not used the "Autumn" Protector should procure some of them. They are made like the summer shades, but covered with a transparent material, and are most useful. By using these shades, clean, well-developed blooms are obtained, and many varieties that will not open during a damp, cool season such as the present come out quite easily. Roses have bloomed remarkably well, but their beauty has been marred by the incessant rain. These shades can be had from Mr. John Pinches, Camberwell, and repay the small outlay in aiding rosarians to cut good blooms in any weather.—E. E. F.

Planting Hardy Flowers.—The note by "J. L. E.," page 437, issue August 31, is a timely one. The reference to the preparation of the soil is important, as thousands of plants are put in annually without any previous preparation of the soil, and when they do not succeed, the owners wonder why. The great majority of hardy plants will grow if merely heeled-in in the ground, and it is owing to their hardness that they often get badly planted. Autumn planting is much better than spring planting, as a rule, as the plants put in in the autumn grow so much stronger the following summer. I have both planted and seen others plant hardy perennials in autumn and in spring, and never found the latest-planted ones to do as well as the others, with the exception of the Pyrethrums. A deep, rich loam, or a deeply-trenched poor soil moderately enriched with manure, will prove a far superior rooting medium to one, however rich it may be, which is simply pricked over on the surface and left with a hard, unbroken pan below.—B.

A Useful Chinese Vine.—Numerous species of *Vitis* have been introduced into our gardens from China during the last ten years. Among these one of the most distinct and useful is *V. henryana*. A particularly valuable asset is that it is self-clinging. The pinnate leaves consist of five leaflets, the central and largest leaflet being 2½ inches to 3 inches long and an inch wide. The mature leaves are dark green, with silvery markings along the principal veins. The young shoots and leaves are red in colour, the under side in particular being a rich shining metallic red. In autumn the leaves assume bright red tints, the silvery hue of the veins becoming even more conspicuous. Experience, so far, with *V. henryana* seems to suggest that it is not perfectly hardy during a severe winter in exposed positions, though this may be only in a young state. A plant growing vigorously on a sheltered north-west wall, where it has passed unharmed through five or six winters, suggested the writing of this note. Under glass in a cool or cold greenhouse and corridors the red tints of *V. henryana* are even more beautiful. Cuttings made of the young growths root readily in a close frame during late summer and autumn.—A. O.

The Chimney Bell-flower.—Quite recently, when looking through the glass department at the trial grounds of Messrs. Sutton and Sons, Reading, I was struck with the many giant examples of this old-fashioned perennial, *Campanula pyramidalis*, then in the heyday of their flowering. The plants were of such exceptional size and ornamental value that one naturally enquired by what special

method such grand specimens had been obtained. In the ordinary way the seeds are sown in spring, pot culture being resorted to all along the line, the flowering resulting when about eighteen months old. The system employed at Reading is somewhat different, and is both simple and economical. It is as follows: A seed-sowing is made early in the year, and the young plants, having been grown on, are planted out in the open, where they remain not only the whole of the first winter, but right away into the autumn of the second season, when they are lifted and potted. In this way, and accorded elbow-room, giant rosettes result at a minimum cost of labour and trouble, any plant attempting to spike in the meantime being discouraged. Given cold-frame treatment after lifting, the plants are brought into the conservatory in the early summer-time to flower, being then about two and a-half years old.—E. H. J.

The Famous Auchmore Vine.—Although usually spoken of as the Auchmore Vine, this famous Grape Vine is at Kinnell. Both houses are, it is true, on the one estate, and are the property of the Marquis of Breadalbane. While the gardens at Kinnell and the surrounding district are very interesting, it was the Vine that was the main reason for our pilgrimage on a recent August morning, and I will confine my few remarks to this wonderful object. The house, which is entirely filled with this one Vine, is 172 feet long and 15 feet wide. The stem, 9 inches from the ground, girths 38 inches. The whole Vine is in the best of health, and is carrying a heavy crop of excellent Grapes. The bunches are of fair size, some of them scaling over three pounds, while the berries are large, with heavy bloom and excellent finish for a Black Hamburg. Roots of this Vine have been found in a park 150 yards distant from the house. It is truly a wonderful sight, and the greatest credit attaches to the several gardeners who have had charge of this Vine during its eighty odd years of life. Mr. Easson, who at present has it under his care, is maintaining to the full the skilful treatment that has always been extended to it, and Lord and Lady Breadalbane must be justly proud of their unique Vine, of which they take such care.—C. BLAIR, *Preston House Gardens, Linlithgow.*

The Madonna Lily.—The illustration of the bed of Lilies, page 436, issue August 31, is very charming, and Mr. Jenkins, on the same page, gives some concise, useful hints on the planting or transplanting of the bulbs. I for one would have liked to see some reference to the dreaded disease by the same writer, as about twenty years ago I had to deal with large beds of this Lily, which were at the time badly diseased. I had at that time just taken charge of a large garden, the vegetable garden alone covering an area of six acres, and these Lilies were mainly grown in two borders, one very dry, the other medium. The plants were very badly diseased, so early in the autumn the bulbs were lifted, soaked in water for a few hours, and then replanted in another quarter of the garden. The bulbs were never exposed to the air from the time they were lifted till they were replanted. The following year the plants were less diseased and flowered better. After three years had passed, the bulbs were once more lifted and replanted in a fresh border, but although they did very well, the disease never entirely disappeared. Manure was not put in, as the soil had been manured for other kinds of crops. Those bulbs left undisturbed practically died away.—Avon.

Fremontia californica.—I was pleased to see a reference to this flowering shrub on page 423, issue August 24, by "S. T." It seems to me that it is a scarce shrub in this country, and deserves to be more widely cultivated. At Crag Head, Manor Road, Bournemouth, there are two specimens growing on the north side of the residence of G. J. Fenwick, Esq. One is a splendid shrub—a tree I ought to say, perhaps, as it is nearly fifteen feet high—and during the flowering season was a beautiful object indeed. This residence is close to the sea, the south side facing it, and as the east winds are badly felt there at times, perhaps the *Fremontia* would not succeed as well there as it does on the more sheltered north side. In more inland districts the shrub would do well in any position if not unduly exposed to the east winds. The rooting medium is of a light nature and well drained.—B.

An Extraordinary Madonna Lily.—I am sending some flowering stalks of *Lilium candidum*. I have had the bulbs three years now, both single and in clumps. The bulbs have always been in fine condition and mostly of large size, but all have malformed blooms similar to those enclosed, and have been so each year. Some clumps have eighteen to twenty bulbs and stalks. Last season they were even stronger than this, and many were 6 feet to 7 feet high. I have seen the same result in two other gardens, where the stock came from the same source, unfortunately, through seeing the grand bulbs and condition of those I bought. I may say some have been grown south and some north of my cottage, and those in the other gardens are in quite different soil. Last season I parted some of the clumps and planted them singly in a well-manured trench (after Sweet Peas) and extra deep, but they are just the same this year. Can you tell me the cause of this, and the remedy if there is one; or shall I burn the lot? I may say I have some imported bulbs in the same border which have flowered splendidly this season, one with twenty blooms on a stem.—J. W. HATCHETT, *The Box, Cowbeech Hill, Hailsham, S.O., Sussex.* [We had the largest of the spikes sent by our correspondent photographed, and sent the photograph to Mr. E. A. Bowles, who is so well versed in abnormal plants. He replies as follows: "Surely the photograph is of *Lilium candidum* flore pleno? It is unusually fine, but I think in hot seasons I have seen it almost as long. Of course, the double form of *candidum* is not beautiful, as the doubling is really a case of proliferation of the axis, with perianth segments at intervals. I see Dr. Masters writes of it in 'Vegetable Teratology,' page 286: 'There is in cultivation a variety of the white Lily, *L. candidum*, sometimes called the double white Lily, in which the segments of the perianth, in place of being arranged in two rows, are greatly increased in number, and disposed in a spiral manner. In these flowers not only are the stamens and pistils thus modified, but also the upper leaves of the stem.' They will never go back to the normal form, and must have been sent out through

mixing of stocks in a nursery. I showed the photograph at the meeting of the scientific committee of the Royal Horticultural Society on Tuesday, the 27th ult. No one there had seen so fine an example before. One member, Mr. Worsley, had seen it near Cambridge this year. I feel sure it is an extra fine example, but the bract-like perianth segments we all thought were rather narrower than we had seen before. It would be a pity to destroy the bulbs altogether, and it would be interesting, if the owner would grow a few for a season or two, to

A SINGULAR FLOWERING SPIKE OF THE MADONNA LILY.

watch how constant the habit is and if other seasons affect it at all, or, failing that, I would grow and watch it, and perhaps Mr. Chittenden, Director of the Wisley Gardens, and the Kew authorities would also do so."—Ed.]

September 17.—National Dahlia Society's Exhibition at the Crystal Palace (two days).

September 18.—North of England Horticultural Society's Show at Leeds.

DAFFODILS IN ROSE-BEDS.

FOR those who have ample room for all the Daffodils and all the Roses they wish to grow in their gardens, I am by no means sure that I would recommend as an ideal method growing both together in the same beds or borders. There is, however, a period, after the Roses have been pruned in the spring, when the Rose-beds look very empty and uninteresting, and those who desire something of interest in their Rose-beds at this period will find Daffodils very useful to supply interest to the beds and to light up the garden.

Others there are—and I am myself among the number—who find they have not room in their gardens to grow all the flowers, both of Daffodils and Roses, which they wish unless they adopt some method of this kind. For some twenty years I have practised this method, and the Rev. J. Jacob has suggested my experience might be of interest.

The disadvantages of the method are that the constant supply of manure given to the Roses, particularly in the resting season of the bulbs, is supposed to be unsuitable for Daffodils, and besides this the flowers, especially in windy weather, are apt to get badly scratched by the thorny stems of the Roses; while from the other point of view it is thought that the Queen of Flowers is impatient of any rival sharing in her palace, and that the disturbance to the roots of the Roses when the bulbs are lifted at the height of the growing season is much to be deprecated.

There is something in all these objections, but the disadvantages may be minimised with care and proper treatment. To begin with, the right kinds of Daffodils must be selected. There are some which certainly resent this treatment. The strong food is too much for them, and they either do little good from the start or become diseased after the first year or so. For the most part strong and vigorous growers must be selected; but when the right kinds are used they often do amazingly well and give very fine flowers, the bulbs often increasing faster than I could wish. Besides this, to succeed with this method care should be taken not to put on a heavy dressing of manure in the autumn and leave it there all the winter. This is a bad plan both for the Roses and the bulbs, and its injurious effect on the Daffodil leaves may often be plainly seen, particularly when growth has suddenly been checked by a February or early March frost.

It is also of much importance for both the occupants of the beds to keep the soil sweet. This is most readily accomplished by recourse to a dressing of lime from time to time. Although I am in the habit of administering this whenever I think it is required, I fancy its effect is particularly beneficial about the end of May or early June. Basic slag has a somewhat similar effect in sweetening the soil, but I have usually employed this in winter or early spring. Then as to the scratching of the flowers and leaves, this is a trouble at times in windy weather, but it need not be serious. The remedy is simple—prune early and prune hard.

TULIP MURILLO, A BEAUTIFUL DOUBLE VARIETY WITH FRAGRANT, PÆONY-LIKE FLOWERS.

Lifting the Bulbs is certainly rather a troublesome business. It must be done early—by the end of May—while the foliage is strong and will withstand a good tug, and it must be done carefully so as to injure both roots and shoots of the Roses as little as possible. I admit to a certain feeling of relief when it is over. It must be done frequently, at least every three years, and perhaps every other year is better. In order to facilitate it the bulbs should not be planted too deep, but they must be deep enough to be safe from injury during the summer hoeing. I often find it convenient when lifting the bulbs to break up the clumps, and replant at the same time a single bulb in place of each clump lifted. As soon as lifting is finished, stamp the bed well down and give a good watering for the sake of the Roses, and it will be found they have suffered very little, generally not at all.

The Best Varieties.—I have said strong growers should be chosen. Emperor, Empress, Victoria, Barri conspicuus and Autoerat all do well, and I do not get better Gloria Mundi or Albatross anywhere in the garden than in my Rose-beds. Rather curiously, Seagull is not quite so satisfactory for the purpose, and if used is better kept to the edges of the beds. This is also the case with most of the Leedsis, except Mrs. Langtry. Maximus is certainly capricious. Often it will do well for several years, and then suddenly and without warning become diseased. Lift it at the first sign of this happening and replant elsewhere. King Alfred, so far, has been a complete failure in Rose-beds; so have many of the newer Daffodils, even strong growers like Brigadier. Later on, when they are more common, and when, instead of growing on all the offsets, we are able to reject the weakly ones, these may be useful, but not now. Orangeman, however, has done well; so has Eyebright, but it increases too rapidly. The Tazettas do well in a sheltered spot, and Elvira (Poetaz) has been a great success for many years. Poeticus recurvus, the ordinary

Pheasant's-eye, is most successful in the rich soil of Rose-beds, and ornatus is fairly good; but many of the modern Poeticus varieties are hopeless failures. Almira I have tried over and over again, always with the same bad result; so, too, Juliet, Musidorus, Comus and Sonnet. Chaucer and Sidney, however, seem a little better. Most of the white trumpets, like tortuosus, are to be avoided; but Mme. de Graaff has done well for several years.

On the whole, the gains far exceed the losses, and I recommend the experiment to all but those who have room unlimited or limited desires in their gardens.

WHITE ROSE.

A BEAUTIFUL DOUBLE TULIP.

PREVIOUS to three years ago I must confess that the double-flowered Tulips held no charm for me. Their stunted, ragged-looking and oftentimes green-tinged flowers were to me an eyesore, and they found no place in my garden. At that time, however, a Tulip-loving friend, whose blandishments are second only to his love for the flowers, presented me with a dozen bulbs of Murillo and persuaded me to plant them. I did so, and the next spring received the most pleasant surprise that I had experienced for many a long day. Now the thought comes that there may be others who abhor the ordinary double Tulips just as much as I still do, but who would, if they knew it, welcome Murillo with open arms. For you must know that this is no ordinary Tulip. It is true that it is an "old one," and can be bought for 10s. a dozen; but what matters that? Indeed, its cheapness is a boon to those who cannot afford to purchase the more expensive and, perhaps, aristocratic varieties that our friend Mr. Jacob loves to gloat over. Perhaps the best way to describe the blooms of Murillo is to liken them to a miniature Pæony, which, indeed, they closely resemble when fully open. Then its colour is such a delightful combination of rose flushed with white that ladies

simply rave over it. In addition, the blooms are decidedly fragrant, an attribute that perhaps some live bulb-dealer will one day credit to those few Tulips which possess it when describing them in his catalogue. Then the blooms of Murillo last so long, either on the plant or in a cut state, and it has a dwarf, sturdy habit that renders it valuable for bedding purposes or for the front of the border. What more would we desire in a Tulip? Beauty, fragrance, lasting properties and sturdiness are all there, and the bulbs can be had for 10s. a dozen! Perhaps Mr. Jacob will one day give us a list of cheap—really cheap—good single and double Tulips, and if all are as good as the subject of this note and illustration, he will call down upon his head the blessings of many readers of THE GARDEN. H.

LATE TULIPS FOR BORDERS.

THE superb beauty and stately habit of the Darwin and May-flowering Cottage Tulips attract hosts of admirers, and bulb-growers tell us

there is an increasing demand each succeeding year for the best varieties. This is not surprising, for coupled with brilliant colours, for size and substance, more particularly in the Darwin section, the May-flowering Tulips are unequalled. In habit and appearance generally they are distinct from the early-flowering Dutch varieties.

When first raised and introduced from Holland, their advance in popularity was slow, the reason for this being the feeling that, flowering in May, they were unsuitable for bedding, it not being possible to clear the beds in time for the Zonal Pelargoniums, Fuchsias and similar plants. Tulips of such exquisite beauty, however, could not be long ignored, and, from being planted in limited quantities in borders, their popularity has increased by leaps and bounds. For general bedding their late-flowering character may be somewhat of a hindrance, but this in the garden, as a whole, is a distinct advantage. Years ago, except for a few Old English Tulips and one or two species, there was a distinct break in the floral display of the borders between the bulbs of April and the flowers of June. The beautiful May-flowering Tulips have done much to bridge over this gulf.

Even if not extensively grown for garden decoration, they are worth special attention for cut-flower purposes. With stems 2 feet to 30 inches long, the Darwins especially being stiff in stem and as straight as an arrow, they are the acme of perfection among Tulips for vase decoration, both in form and lasting qualities.

In making a selection of sorts to cultivate, the grower will find a very wide range of colour at his disposal. The Darwin section includes many shades of scarlet, crimson, red, purple, pink, lilac, rose, mauve, white and glossy maroon or black. The most important colour missing from the Darwin Tulips is yellow. This and many other shades of exquisite beauty are to be found in the May-flowering Cottage Tulips. Bulb-growers, to meet

the demand for a yellow Darwin Tulip, when specially requested, supply the May-flowering Cottage variety Bouton d'Or, which in habit resembles the Darwin section.

The following twelve sorts comprise a useful and varied selection of Darwin Tulips: Clara Butt, soft pink; Europe, rosy red; Farncombe Sanders, vivid red; Glow, vermilion; La Tulipe Noire, the nearest approach to a black Tulip (this variety and Bouton d'Or, yellow, are a lovely contrast when planted in mixture); Loveliness, satiny rose; Margaret, blush to soft pink; Pride of Haarlem, rose red, the largest of the popular Darwin Tulips; Rev. H. Ewbank, a heliotrope or grey shade; Wedding Veil, white, shaded lilac; White Queen, also known as Darwin La Candeur, the best white variety; and William Pitt, deep scarlet.

Six of the best May-flowering Cottage Tulips are Bouton d'Or, rich yellow; gesneriana, scarlet crimson; La Merveille, bronzy red, fragrant; Picotee, white, edged rose; retroflexa, pale yellow, distinct, recurved petals; and vitellina, pale cream.

The cultivation of the May-flowering Tulips presents no difficulties. They are perhaps seen to the greatest advantage when planted in masses, 5 inches to 6 inches apart, in long borders as illustrated. They are also adapted for planting in association with Wallflowers, Polyanthus, Arabis and other spring-flowering plants, the two providing an almost indescribable wealth of colour. The perennial borders may be thinly planted with the bulbs either in groups of distinct varieties or in mixture, as the Tulips will not harm the permanent plants, while they will brighten up the garden considerably in early May. A. O.

SOME INTERESTING CROCUSES.

THERE are so many things in gardening that no fellow can, or ever will, understand—historically, practically and theoretically—that it almost might be called a science of surprises. It is full of all sorts of shocks, both pleasant and unpleasant.

There are two beautiful Liliun auratum. It is their second year in the ground. To-day they are the picture of health and give promise of abundant bloom. The next morning the leaves are drooping and the buds flabby and flagging. Something has happened. We say "sun-stroke," but we do not really know. This is a practical shock. We all know the sort of thing very well.

Another sort of shock is more a sad surprise than a shock. I had one the other day, or, rather, a whole series of little ones. I was looking where I could buy the species Crocus called Sieberi, Imperati, susianus, biflorus and tommasinianus. One after the other I took up my bulb lists. Pearson's? No. Hogg and Robertson's? No. Sydenham's? No. Dickson's of Belfast? No. Carter's? No. Hartlands'? No. Bath's? No. Well, surely they will be in Sutton's? No, not all of them; even there only biflorus (the Scotch Crocus) and susianus

(Cloth of Gold) When I had sufficiently recovered, I began to ask myself what all this meant. It was indeed surprising to find in this age of rock gardens and cheapness these little floral gems unlisted, and corollarily I can only presume unknown and ungrown, for nothing is more certain than that if they were not my first they would not be my second.

These beautiful little flowers would be everywhere if people only knew how easy they are to grow and how cheap to buy. Any good garden soil makes them quite happy. They flower in advance of the Dutch varieties, and are much smaller and more dainty-looking. Biflorus is a slender, delicate white, with dark-pencilled sepals. Susianus, when open, is a rich deep yellow self; when in bud it is a study in chocolate and gold. Sieberi is a fat, jolly little fellow in a pretty mauve frock. Imperati is more slender and grows taller. When fully open it is a pale mauve, but in the bud stage it looks as if it were a combination of buff and deep purple, owing to the external colouring of the perianth. Tommasinianus is silver grey outside, and almost a lavender when the flower is expanded. Its orange stigmata are striking. All these five varieties may be left undisturbed for two or three years, when, like all others, they are all the better if they are taken up, divided and replanted in fresh soil. If the seed-pods are allowed to open when they appear on the surface, it is very easy to get colonies of seedlings.

New Seedlings.—Within the last few years some Dutch firms have put some charming new florists' varieties into commerce. A few of the best and most distinct are included in the following list, all of which I can confidently recommend: Distinction, a small flower, needs thick planting to make a good effect, a mauve pink; very distinct and the nearest approach to a pink. Dorothea, soft pale lavender mauve, an exquisite shade; does very well in pots. Hero, dark shining purple; an immense flower, very late. Kathleen Parlow,

a large pure white of great substance, and set off with prominent orange anthers; exhibited in fine condition by Messrs. Bath at the Royal Horticultural Society's shows this spring. Margot, heliotrope and lavender; a striped flower of great size and substance; pretty in the bud stage; tall grower. May, the writer's favourite white, not so large and tall as other varieties, but of extra fine form; stands wind and rough weather well. Pallas, white, with lilac veinings, very large, fine orange anthers. Sir John Bright (John Bright), a good, very deep purple, enormous bloom, and valuable because of its earliness.

A Crocus which I see highly recommended in the trade lists is Harbinger, a dark purple, said to flower three weeks in advance of all Crocuses. I have not experimented with it myself, but it must be worth while giving a few a trial. A broad purple mass of Crocus in March is a delightful sight, and there is no doubt the effect might be made more lasting by a judicious mixture of varieties, say, Harbinger (if it is what it is claimed to be), John Bright, purpurea grandiflora and Hero. P. J.

THE RAISING OF BULBS FROM SEED.

SO little done, so much left to do," were the last sad words of a great man who now lies among the Matoppo Hills in South Africa, and whose life was employed in a work even more important than horticulture. But that will be my epitaph, anyway. The raising of bulbous plants from seed has its disappointments, its periods of weary, weary waiting; but in fascination it surpasses all other forms of speculative and experimental gardening as I know them. Let us first take, by way of a contrast, the case of that popular annual flower, the Sweet Pea. We do our

A BORDER OF MIXED MAY-FLOWERING TULIPS AT KEW. NOW IS THE TIME TO PLANT.

crossing, sow the seed, and in a couple of years from then we have perhaps a series of new varieties, good, bad and indifferent, principally the last two. If by a stroke of luck we are rewarded with a prize, it goes on the market, and in a couple of years more is played out; anybody may have it. How different with a bulbous plant. I have seedling Daffodils sown in my first year of hybridising, distinguished by the letter "A." The years have rolled on and I have now arrived at letter "I," and some of my "A" seedlings have not yet flowered. Seedlings of some of the Crocus species sown four or five years ago last spring showed each but one spindly leaf. My gardener said he could hardly "design" them; "discern" I think he meant.

And then, when we have at last acquired something really good in bulbous plants, oh! the time it takes to work up a stock! Among my Daffodils I have particularly noted that if at any time I have selected what has proved to be a rather *indifferent* seedling, it has multiplied after the manner of rabbits or white mice; but with the choicest things the contrary is generally the case. Among records I have made is the following: The first time I ever showed seedling Daffodils of my own raising was in a class where three varieties were required. These were duly put up and a first prize taken. Of my pet flower of the bunch, and which was undoubtedly the finest of the three, I now have three bulbs only, while the other two have run into quite substantial stocks. I do not know that this is always the case, because I had it from the raiser, that the superlative Daffodil Empire is a most prolific increaser, and I have heard of a few other fine things that increase well; but I think one may say, without any fear of contradiction, that these are only the exceptions that prove the rule.

Those going in for saving seed from bulbous plants will find the crop of seed considerably affected by the seasons. Here, for instance, we have saved a comparatively small quantity of Daffodil seed this year. Although the pods looked quite as promising as usual, they were not well filled; this, I suppose, was the result of a very dry April and May. The best crop of seed I have ever obtained from my little Irises of the *reticulata* section was in a spring when we had a warm, sunny spell just when they were all in flower. This brought out the bees in swarms, and they were very busy with the flowers when the sun was on them. The following spring was a cold and dull one, and the seed crop an almost entire failure. The de-anthering and cross-pollinating of small bulbous plants is subtle and very intricate work. I am afraid I let the former process slide in a great many instances. It has always struck me that a watchmaker would be the

man to make a hobby of it. He would be well equipped by practice and experience to do it effectually.

I am in doubt as to the preferable qualities that would go to make up a successful raiser of bulbous plants. We might take the case of a man who was capable of taking great care, infinite pains, who was never daunted by the frequent failures encountered, but kept pegging away until he had successfully effected the different crosses he desired to make; but if he had not the eye and the right taste in *selecting* his things when he had

and at no time is it so bright and well defined as in Heroine. Take away the colour from Albatross, and I would then much prefer Seagull. Take away the beautiful red edge from Heroine, and then most of its value would be gone. But it never varies, and herein is its superiority to Albatross most chiefly shown. At present it is expensive, but as it is a good doer on all but very heavy, cold soils, it will doubtless soon be offered at a lower figure. Many who would like to own a bulb will welcome that happy time and hope that it will not be long delayed. POETICUS.

NARCISSUS HEROINE, AS SHOWN BY MESSRS. PEARSON AND SONS OF LOWDHAM AT THE BIRMINGHAM SHOW.

flowered them, of what avail would all his labour be? A combination of all the qualities I have named would be ideal.

Rye.

F. HERBERT CHAPMAN.

A GOOD NEW DAFFODIL.

NARCISSUS HEROINE is one of the specialities of the firm of Messrs. J. R. Pearson and Sons of Lowdham. It is a singularly attractive flower, and the writer can well remember its first appearance on their stand at Birmingham about three or four years back. The catalogue comparison between it and Albatross hardly does it justice. The latter flower is very fickle in its colouring,

and at no time is it so bright and well defined as in Heroine. Take away the colour from Albatross, and I would then much prefer Seagull. Take away the beautiful red edge from Heroine, and then most of its value would be gone. But it never varies, and herein is its superiority to Albatross most chiefly shown. At present it is expensive, but as it is a good doer on all but very heavy, cold soils, it will doubtless soon be offered at a lower figure. Many who would like to own a bulb will welcome that happy time and hope that it will not be long delayed. POETICUS.

COLOURED PLATE.

PLATE 1454.

BROWN AND BRONZE TULIPS.

ONE of the Tulips in the plate belongs to that particular type which is so often, but erroneously, put under the head of Darwins. The true and original strain, which was introduced twenty-two years ago by Messrs. E. H. Krelage and Son of Haarlem, were all either *byblœmens* or roses. There was not a single bizarre (that is, a flower with a yellow base) among them. It is a thousand pities that this distinction is not generally recognised, and that all yellows are not placed under the head of May-flowering or Cottage, which undoubtedly they are. Some of these Darwin-shaped yellows, like Golden Bronze, have a most distinct tone in their colouring, and one that is seldom met with in any race of flowers. We do come across some of the shades in the *Nemesias*, for example; but such browns as are found in *Clio*, *Goudvink*, *Quaintness*, *Toison d'Or* (which I fancy is the older and more correct name for Golden Bronze, unless it is Mahony, which is synonymous with *Toison d'Or*) and the "broken" *Goldmine* are very unusual.

The other flower which is figured in the coloured illustration is the exquisite *Louis XIV*. It is an aristocrat even in an aristocratic and imperial race. The rich bronzy purple of its brown-edged petals is so suggestive of refinement and restraint. It is so sure of itself. It needs no brighter hues. Both these varieties are to be found in Messrs. Barr and Sons' collection, and they very kindly supplied the flowers from which the coloured plate was prepared.

The following list of browns will be useful to those who wish to add some to their collection, and as they may wish to know something about them, I append brief descriptions.

Clio, called also *Bronze Queen* and *Biscuit*, is a fine tall plant bearing large flowers of the shade of a well-baked biscuit. There always used to be a large bed of this variety every year at Glasnevin

COTTAGE TULIPS.

"Golden Bronze" (left).

"Louis XIV." (right).

Botanic Gardens, Dublin. I do not know if it is still continued, but Sir Frederick Moore has more than once told me how greatly it was appreciated by the visitors. Under the name of Clio or Bronze Queen it may be obtained from most bulb-dealers at about half-a-crown a dozen.

Goudvink is its counterpart in "tortoiseshell." I have now a good large bed of this variety, and for a long time I was at a loss to get hold of a word to describe its peculiar reddish brown. One day a visitor exclaimed, "Why, there's a tortoiseshell-coloured one!" It has been tortoiseshell ever since, for it is more like the comb in my dressing-bag than anything else. I think Mr. Bourne of Bletchley can supply this at about half-a-guinea or 12s. 6d. a dozen. It is a very fine thing indeed.

Toison d'Or, or, as the illustration has it, Golden Bronze, is a beautiful shade of rich brown-yellow. Externally it is practically a self, but inside there is a halo of a deeper shade round the yellow base, which gradually tones down to the colour of the exterior as the top of the petals is approached. Messrs. Barr and Sons list this at 4s. 3d. per dozen. It is not very often met with in catalogues. In fact, all of these browns are a bit "out of the way."

Quaintness is, roughly speaking, a pointed-petalled Golden Bronze. It has not, however, quite such a rich look about it. It might have had a thin wash of grey, just to tone it down, as it were—a sad golden brown is the description in my note-book. It is expensive. I see it priced in the list of Messrs. A. Dickson and Son of Belfast at half-a-crown a bulb. I also see it in Messrs. Barr's.

Goldmine I have grown for many years, but my stock is still only a small one. I think I had it from Messrs. R. H. Bath of Wisbech, but I cannot see it in their 1912 list, nor can I meet with it elsewhere. It is a study of Cbameleon in brown, and has just that blotched look about it which I so frequently find suggests to my visitors a bird's egg. I do not say it is, but it might be the rectified form of Toison d'Or or Golden Bronze. My old gardener, who, if he could call a word wrong was certain to do so, would have spoken of it as a "marrigated" Golden Bronze. I hope someone has a stock of this singularly effective and, to so many, very attractive Tulip. Some of us, I feel sure, would like to know.

Louis XIV. I have already partly described. I need only add that it is a very tall grower and has immense Darwin-shaped flowers of that beautiful bronzy purple which we partly get, but in a much paler shade, in the standards of the Spanish Iris Thunderbolt. So highly do I think of this variety that I have no hesitation in giving it a place among the "great." *It is a great Tulip.* As Messrs. Barr have it, "very tall and stately and remarkably handsome." There is something about these brown and bronze Tulips that appeal to one, and the liking for them grows the more one contemplates the flowers.

JOSEPH JACOB.

CLIMATIC INFLUENCES ON HYBRIDISATION IN 1912.

TO those entering in these later days upon the work of raising new seedlings of Narcissi there cannot remain the slightest hope of emulating the splendid achievements of those who, in some cases for a generation, have devoted

themselves to the work, with results which have amazed us all. With workers such as the Rev. G. H. Engleheart, Messrs. Crosfield, P. D. and J. C. Williams, Copeland, Haydon and Backhouse, only to mention a few of the giants of the cult, already holding the field, there exists now for the new-comer only the very barest and most unlikely chance of producing new varieties at all comparable with those created by the men who

of frequent occurrence, sometimes during several successive nights. The period in question covered what is usually the time when pollinating of the Narcissus is carried out. Coupled with this state of things was a season of equally abnormal earliness in the flowering of the Narcissus, due probably to the great heat of 1911, coupled with the drought of that year and the absence of severe winter frosts, resulting in the ground still retaining an unusual warmth.

In 1911 I pollinated my first flower on April 12; in 1912, on March 24, nineteen days earlier than the preceding season. As to the results following this unusual combination of unfortuitous circumstances, it may be well, before giving the data upon which my conclusions are founded, to state generally what these conclusions are, so that the data may be considered in relation thereto. My main conclusion is that the injury resulting from

DAFFODILS NATURALISED IN THE WOODLAND AT CAPTAIN S. WALTER'S, EAST FARLEIGH, KENT.

had so very long a start. They cannot now be overtaken.

Still, there remains for all of us a minor work—one of great interest and possible use to others—the compilation of statistics connected with the varied operations of hybridising, and so accumulating data which, if collected with scientific care and accuracy, may help to build up a store of facts from which in the future the laws and abstract principles connected with the subject may be recognised. And in this connection it would seem that it may not be without use to consider the lessons taught by the climatic influences on hybridisation in the very exceptional year now closing.

First, then, to recall the climatic conditions of the early months of 1912. During March and April and a part of May a period of abnormally low temperature was experienced. Frosts, often of exceptional intensity for the time of year, were

the adverse climatic conditions sustained in the trumpet section was trivial when compared with that sustained by the Medio and Parvi varieties. The reason will be afterwards considered.

Of the trumpet varieties pollinated by me in 1911 (a fairly normal season), 30 per cent. seeded. In 1912 within a small fraction of the same percentage resulted. In detail, as examples: In 1911, Mme. de Graaff as seed parent, ten seeded out of forty-one distinct crosses made; Weardale Perfection as seed parent, not one seeded out of five distinct crosses made; Duke of Bedford as seed parent, three seeded out of three distinct crosses made; King Alfred as seed parent, one seeded out of five distinct crosses made. Pollen of had general reputation for potency, used for experiment, accounts for the failures in some cases; but the conditions were identical in this respect in 1912. In 1912, Mme. de Graaff as seed parent,

ten seeded out of thirty-nine crosses made; Wear-dale Perfection as seed parent, eight seeded out of thirteen crosses made; Duke of Bedford as seed parent, five seeded out of six crosses made; King Alfred as seed parent, four seeded out of six crosses made. And so, in the trumpet section, 1912 does not suffer by comparison with 1911, but rather the reverse.

A very different story has, however, to be told when the Medio and Parvi sections have to be dealt with. In my garden devastation reigned supreme. A few examples will serve to show the general results. In 1911, Lulworth, every bloom seeded; in 1912, not one in seven crosses made. In 1911, Will Scarlett, 50 per cent. seeded; in 1912, not one in six crosses made. In 1911, Lady M. Boscawen, every bloom seeded; in 1912, 50 per cent. only. In 1911, Southern Star, every bloom seeded; in 1912, none. In 1911, White Wings, every bloom seeded; in 1912, two out of nine. And, further, in regard to the number of seeds contained in each pod, the season of 1912 showed a marked inferiority to that of 1911. White Wings, for instance, produced in 1911 five pods which contained together no fewer than ninety seeds, an average of eighteen seeds per pod. This variety is a most prolific bearer. In 1912 the two pods gave twenty-eight seeds (six to the pollen of Warley Scarlet and twenty-two to that of Red Beacon), an average of fourteen seeds. This same percentage of decrease in number was maintained throughout most of the varieties, tending, as it would seem, to evidence a general weakening of the plants for seeding purposes, one result probably of the unfavourable climatic conditions which prevailed. Bernardino and Red Beacon I found this season to be by far the most efficacious pollen parents; also White Knight was good.

In considering the conclusions to be arrived at, the question at once presents itself: Are these various ill-results to be attributed to injury to the female (style and stigma) or to the male (anthers and pollen lobes) reproductive organs of the flower, or to both, and in what relative measure?

I think that the results achieved in the trumpet section as above stated dispose of the idea that any marked injury to the pollen had resulted

from the frosts, and that we have to look rather at the injury sustained by the pistil and style for an explanation of the disastrous results. Obviously in the trumpet section the extended perianth afforded a better protection from the frosts than was provided by the shorter and more widely-opened perianth segments of the Medio and Parvi sections, a mere matter of relative material protection from the frost, and from the sun following too quickly before the frost had disappeared.

further assured by friends who have been this year hybridising Narcissi that the damage in their Medio and Parvi sections has also been exceptionally severe.

CHARLES E. SHEA.

POET'S NARCISSI IN THE GRASS AT KEW.

THE groups and masses of Poet's Narcissi scattered about the grounds at Kew is one of the most effective features in the Gardens in spring. The bulbs are planted freely in the woodland vistas and glades, and are quite at home in the thin grass between the trees. They increase freely and flower profusely year after year. Although the soil in which the bulbs grow is light and sandy, they do remarkably well and produce flowers of good size and substance. Planted in a rich, deep soil, however, the stems will grow taller and the flowers will be larger; but such soil is not absolutely essential for success with these beautiful bulbous plants. In light soil, however, there is always a tendency on the part of the bulbs to increase too fast, and split up into a lot of small bulbs which produce only leaves the following season, but eventually they attain flowering size and bloom freely.

Early planting is recommended for these Narcissi, and the sooner they are in the ground the better after the month of August. Shallow planting must be avoided, especially in light soil, where the bulbs ought to be at least 5 inches or 6 inches below the surface. When planting in grass, the turf may be taken up; then holes may be made with an iron-shod stick or crowbar. Care must be taken that the bulbs rest on the soil at the bottom of the hole, as many failures are due to suspended bulbs in careless planting. After the bulbs are placed in the holes, fill up with fine soil, rake it all over, and then replace the turf, beating it down firmly; or the bulbs

AN EFFECTIVE GROUPING OF POET'S NARCISSI IN GRASS.

Of course, results are materially influenced by local circumstances. In my case the borders, although well protected from violent winds from north and east, are peculiarly liable to severe damp frosts, and gardens situated in more dry and high places may have shown different results; but that does not affect the conclusions arrived at under the special conditions which prevailed, and I am

may be planted with a bulb-planter, which does away with the necessity of lifting the turf. This instrument, on being pressed into the ground and withdrawn, removes a circular piece of turf and soil as deep as desired. After placing in the bulb this will fit back into the hole again. In planting, all formality and regular lines should be avoided, taking care to have irregular groups of all sizes and shapes.

The two principal sorts which are grown, and which are cheap enough for naturalising in grass, are: *N. Poeticus* variety *ornatus*, which comes into flower first of the two, has a pure white perianth with broad and well-formed segments, the eye margined with scarlet. The old Pheasant's-eye (*N. P. variety recurvus*) comes into flower after the above is well over, and forms a valuable succession of flower. It has a pure white perianth of reflexed segments, the eye of which is margined with deep orange red. Very fragrant, it is slightly taller than the earlier variety. Besides these there are many other desirable varieties, while the hybrids of this group include many beautiful forms. W. I

NARCISSUS PALLIDUS PRÆCOX FOR NATURAL EFFECTS.

Owing to the fact that this beautiful early-flowering Daffodil has a decided tendency to deteriorate

between the Filbert trees shown in the illustration. I think you will agree with me that *N. p. præcox* is quite at home here and increases each year. I find in one case seedlings blooming some yards away from the original planting."

THE SEEDING OF DAFFODILS.

HAVING read some time ago with much interest the results of the Daffodil seed crop for the past season, published in THE GARDEN, I am sending particulars of my experience, which may be of some assistance in elucidating the curious results experienced. It will be remembered that April of

and *Parvis*. Of the trumpets about seventy per cent. took—not so bad considering the season; of the *Medios* about twenty-five per cent. took; and of the *Parvis* only about twelve per cent., I think almost in inverse ratio to the normal. I am of opinion that the whole thing is accounted for by the hot sunshine and strong wind. Where the stigma was protected to an extent, as in the trumpets, results were fairly reliable; where more exposed, as in the *Medios*, most of the pollen dried and dropped off before absorption took place; and the *Poeticus* were almost a total failure for the same reason, the stigmas being entirely unprotected from sun and wind.

Perhaps, should similar circumstances again arise, it might be well to moisten the stigmas and tie up the *Medios* and *Parvis* in a paper cone for a day or two until absorption had taken place.

As evidence of the extraordinary difficulty in fertilising during the past season is the almost

NARCISSUS PALLIDUS PRÆCOX, NATURALISED BETWEEN NUT TREES IN THE GROUNDS AT EDEN GROVE, CARLISLE.

and die out when planted for natural effect in many gardens, the accompanying illustration, together with the following letter, kindly sent us by Mr. R. Carruthers, Eden Grove, Carlisle, will be of interest. Mr. Carruthers writes: "I took to the Daffodil somewhere about 1897, and these bulbs of *N. pallidus præcox* would be planted certainly after that year. This variety of Daffodil was planted in clumps of ten or twelve bulbs, the order being given for 100 bulbs. They have had nothing done to them, and simply look after themselves. They are a source of great delight each year, brightening the days of early spring with their sulphur-coloured blooms. A colony of *N. p. præcox* at the foot of the tree of Apple King of the Pippins is a few yards away from those

this year was entirely abnormal—no rain, strong sunshine and excessive wind—with the result that all plants raced into bloom, early, midseason and late, in no sort of order, but giving the hybridist the opportunity of effecting crosses which in a normal season could not take place under natural conditions. Owing to the curious weather conditions, I took rather ample notes, and I think it is possible to assign the reason for the abnormal number of failures in the past season.

I may say that I tried no "freak" crosses; all the pollen plants had a reputation for fertility, and all the seed-bearers were of good repute. I made about one hundred and forty crosses in all, fairly evenly divided between trumpets, *Medios*

total absence of any self-fertilisation. I well remember two beds of *Emperor*, which contained between 300 and 400 bulbs. I fertilised a few flowers with pollen of *Horace* and *King Alfred*. They all produced a certain quantity of good seed, but the remainder did not produce a single pod, although left standing intentionally. The same thing happened with a quantity of *Minnie Hume*. Of those hand fertilised, about thirty per cent. took, but not a single pod was set by natural means.

Invermore, Woking. J. W. JONES.
[Mr. C. E. Shea, on page 463, gives some interesting particulars about the effects of hybridisation during the abnormal spring of this year, and attributes the failure of the *Parvis* to seed to frost.—ED.]

THE FLOWER GARDEN.

SWEET PEA NOTES.

Autumn Catalogues.—It is my intention to devote the major portion of the space at my disposal in some future issues of *THE GARDEN* to a consideration of the varieties offered in the leading specialists' lists. It is acknowledged by everyone interested in the cult of the Sweet Pea that varieties are much too numerous; but as far as I am aware no one has come forward with a really practicable suggestion as to how the state of affairs can be changed for the better. It is a small list that does not embody upwards of five dozen varieties, and some of them include nearer double than quantity. Can the tyro be otherwise than bewildered when he comes to the task of making a selection from so formidable an array of names, especially when he reads the glowing descriptions accompanying each variety?

Individual taste must, of course, mainly govern selections of all kinds of florists' flowers; but the novice who attempts such a thing in Sweet Peas will be apt to come rather a bad cropper, because there are so many varieties too closely alike to justify the inclusion of more than one of them in an ordinary collection. The publications of the National Sweet Pea Society are undoubtedly helpful, but they can scarcely be expected to give a detailed, comparative description of every variety in cultivation; hence it is wise for the uninitiated to secure the advice of an expert friend to start with.

It cannot be doubted that the seedsmen would be pleased to see their way to reduce the lists, but there are, and always will be, people who do not waver in their allegiance to old favourites, and as regularly as the seasons follow each other they ask for them, and it is obvious that the seed-merchants must be able to meet the demand. Well, perhaps we shall see a way out of the corner some fine day.

White Varieties.—When I made mention of two or three white varieties of conspicuous merit I omitted White Queen. In many cases such a lapse of memory would be of no real moment, but in this instance it is of importance, for the simple reason that this is one of the finest whites in commerce and is destined to occupy a high place in future lists. The form of the flower is excellent, the blooms are admirably set on the stem, the plant is a thoroughly good grower, and White Queen ought to have consideration from all purchasers this autumn.

A Farnham List.—Messrs Bide and Sons, Limited, Farnham, have come prominently to the fore in Sweet Peas during recent years, and they have arranged some splendid stands at the

"National," the Royal Horticultural Society and other important shows. Their present list embodies the finest standard varieties, and no novelties are included. This is just as well, unless one can be perfectly sure that the new-comer is good enough to beat any of its predecessors, and this is not an easy matter nowadays. Among the best in this catalogue are: Agnita, cream overlaid delicate lilac; it is a beautiful flower that will appeal to those who admire refinement of colour. Seamew is a splendid grower and produces plenty

of this group that run closely together and are of about equal merit. Edna Harland is another monster flower, the colour being clear, bright pink; notwithstanding its great size it is in no sense coarse; it does not, of course, stand in a class by itself. Mrs. Hardcastle Sykes is still a favourite with many cultivators and exhibitors, and it is decidedly so with Messrs. Bide and Sons, who staunchly advocate its inclusion in collections. I may be allowed one or two lines to call attention to the magnificent flowers which this firm staged at the Royal Horticultural Hall on August 13. They attracted wonderful attention, particularly a perfect vase of the showy Eric Harvey. HORACE J. WRIGHT.

THE BEST GARDEN DAFFODILS.

HOW few of the Daffodils of fifteen to twenty years ago are to be found in the lists of the present autumn! They have gone, dropped out by the wayside in the great race for garden recognition. A process of sifting has been quietly going on. Messrs. Barr and Sons' interesting list of discards has been growing longer and longer. It is only a few of the fittest that alone survive—Emperor, Empress, Barri conspicuous, Mrs. Langtry, Mr. Walter T. Ware's great Parisian find, ornatus, the old as the hills recurvus, the pretty sweet-scented yellow Jonquils and a few more that could be counted on our fingers and toes are the sole remnants of a past of "good things," "great acquisitions" and "distinct advances." The same inexorable law is still at work, and the modern creations of the hybridist must submit to it as their forbears had to do in the past.

Not every Daffodil that has been bought with gold will be among the ranks of the "great." No; far from it; the many will not be even among the "useful." *Sic transit gloria Narcissi.* In time past I went round Mr. Willie Copeland's (we never call him William, as I suppose we ought) Daffodil garden at Kibblestone Hall. "Hallo!" I said, "what have we here?" There was a label. That was all. "Oh!" he said, "it is a grave." "A grave?" "Yes, five pounds are buried there."

NARCISSUS STROBOLI, A GOOD TYPE FOR THE GARDEN.

of charming pale lavender blossoms on stout, long stems. Blue Belle, although it belongs to the now somewhat despised grandiflora group, is a real beauty and fully entitled to more attention; the name truly describes the colour of the expanded flower, which is lavender in the bud stage. Mrs. Stewart Champion, an immense cream pink, has not such a place of its own, since there are several

Brother and sister gardeners, have not we also many of these sad reminders of a too-confiding enthusiasm? Sometimes I fear considerably more than five pounds are in the ground beside what has come to be only a tombstone. Where is White Giant to-day? (White Giant was pictured in *THE GARDEN* Daffodil Number of 1911.) Ask the Brodie of Brodie; ask Mr. C. Lemesle Adams.

Mr. Pinches has invented a simple but effective label to keep away tramps—"Beware of the Lycopodium." Might he not turn his attention to an appropriate writing on the wall for the innocent dreamers who see the exquisite productions of a Williams or a Crosfield already growing in the greatest profusion in their little flower patch?

Mr. Duncan Pearson is one of the downright honest men of the world. He has been busy for the last month (August) catching salmon and trout in Norway. All I know about fishing is that there are long pauses in the sport between one naughty fish succeeding another on the hook. It gives opportunities for reflection and—! In his case, though, at those moments when there was no fish, I think I am safe in surmising there was a Daffodil on at the other end. One by one the new ones would come up for judgment. The fisherman returned home. One of his first letters was to me. Just note what he says: "Comparatively few of the newer Daffodils are any use for general garden purposes. When they are no longer of use on the exhibition table they are no use at all." I am convinced he is absolutely right, and that is what I have been leading up to all this time.

Now, arising out of the above there come the further obvious questions: How are we to know a good garden Daffodil? and which are they? Dealing with the first question, I would reply that it is impossible to tell except by the practical method of growing them ourselves. The two most important requisites are that the variety should be one worth having for its decorative effect; and, secondly, that it should be a good doer. It is in these essentials that shows are so misleading. They tell us neither about the one nor the other. Probably the greatest want in the Daffodil world of to-day is a series of systematic trials carried out in different climates, e.g., North and South, and in different soils, e.g., heavy, light and buttery, where anyone could go and see for themselves the behaviour of lesser-known varieties. It is impossible to discuss in detail all the factors that go to make a plant a good garden one. The bare mention of some must suffice; size, height, season, poise of flowers on stem, adequate foliage, conspicuity of the blooms about the leaves, burning or fading of the red colouring in the cup or eye, strength of stem, lasting qualities, power of increase, and, above all, it must have a good constitution. It must be obvious from this there will be wide differences in the garden value of the various kinds.

I now come to the second of my two original questions. Which are the ones that most nearly approximate to the ideal? Of the ancients I should say Emperor and Barri conspicuous. Among the moderns the following bid fair for fame. But as time is the supreme test of a good vintage year, so it is likewise the final arbiter of the merits of a Daffodil. I am not Father Time, and I beg readers

to remember *errare humanum est*. Taking good old Emperor as typical of a midseason bloom, I would mention as earlies Alert, Stromboli (illustrated on page 466), Duke of Bedford, Golden Spider, Silver Spur and Sir Horace Plunket among the trumpets, and Dandy Dick and Blackwell among the Medios. Then, as later flowers, Cornelia, Cygnet, Cleopatra, Mrs. Veitch and The Doctor for the Ajax section, and for the Barris and "incomps" such varieties as Solfatare, Occident, Steadfast and Amber.

The midseason ones are more numerous. They include such magnificent flowers as Bernardino, Florence Pearson, Noble, Lady Margaret Boscawen, Hall Caine, Torch, Castile, Lucifer, Whitewell, Seagull, Coronet and Olympia. This last is a yellow

Sirdar, Mermaid and the late-flowering H. C. Bowles have left White Queen far behind as decorative plants; while among the older type with smaller cups, Evangeline, Constance, White Lady and Countess of Southesk are new varieties of great value.

The Poets I must leave alone. It is almost six to one and half-a-dozen to the other as far as garden decoration goes. I cannot make up my mind about them. I am as changeable as a weathercock. However, Horace, Cassandra, Ben Jonson and Acme are exceptions. About these I do not think I do change. Last of all we have the Poetaz. They are most useful, and I am told they are at last becoming popular. The best are Aspasia, Orient, Elvira, Irene, Jaune à Merveille and Sunset.

If my choice were limited to three, I would take the first two and the last; if to one only, then Orient. Years ago I backed my opinion by a purchase from Mr. Engleheart. It is enough, perhaps, to say I have never regretted it.

JOSEPH JACOB.

NARCISSUS AVALON, A GOOD TYPE OF AN EXHIBITION FLOWER.

Ajax of huge dimensions, with a perianth of a slightly paler shade than the trumpet. The plant is a vigorous grower and fairly free flowering. It bids fair to be a serious rival to Emperor. Of Dutch extraction, it is now found in numerous British catalogues, but it ought to be in all, just as it should be in every garden. The bulbs are as large as croquet balls. They would be worth something for decorating a shop window in bulb-time if for nothing else. I now come to the Leedsii. In no class have greater improvements been made in recent years. The "giants" are an immense acquisition to our best garden Daffodils. Such things as The Fawn, Thora, Lowdham Beauty,

NARCISSUS AVALON.

Just as Zwanenberg, that marvellous large and tall white trumpet which was shown by Mr. C. G. van Tubergen at the Daffodil exhibition in London, stands out as the garden plant of the year, so, according to my judgment and liking, does Avalon as a show flower. I have been fortunate in obtaining such an excellent likeness of it as that given on this page. When I say that the perianth is of a pure recurved white, and that the yellow eye has a well-defined rim of bright red, readers will be able to form a fairly accurate idea of what the flower is like. Naturally, one compares it at once with the now famous Challenger, which it very much resembles. After carefully weighing the merits of the two, I am disposed to say that Avalon is the more perfect flower. It is whiter in tone, even more symmetrical in shape, quite as well balanced and quite as large. It differs from the older variety in having a rather smaller centre in proportion to its size, and a rather narrower rim of red to the cup. My measurements are: Diameter of perianth, 3½ inches; diameter of cup, a bare seven-eighths of an inch; width of red edge, three-thirty-seconds of an inch. It was exhibited by Mr. A. M. Wilson of Shovell, the raiser, at the London Daffodil Show this year, and is the result of crossing Beacon (seed-bearer) with an unnamed seedling Poet. Mr. Wilson tells me that it is a tall, robust plant, and, as far as he can judge, it is likely to be a "good doer." As the bloom exhibited was, I believe, the first and only flower that it has so far produced, it is obvious that it must be two or three years before any bulbs can be offered for sale.

P. J.

THE ROCK AND WATER GARDEN.

A CROCUS FOR THE ROCK GARDEN.

AMONG the many species of early spring-flowering Crocuses, few are brighter or more pleasing than *Crocus versicolor*. The flowers, of comparatively large size, glistening white, or sometimes flushed with lavender, and veined with rich purple blue, often appear in February, and are a great delight at so chill a time of the year, the stigmata of a rich golden colour making a brilliant contrast to the segments.

As the flowers appear to open only in bright light, they are best disposed in sunny nooks about the alpine garden, where the life-giving rays of the sun (so welcome, but, alas! so fleeting at this time of the year) can fall upon them. As with most of the *Crocus* species, they are easily accommodated in our rock gardens. The ordinary gritty soil

and their beauty retained for a considerable time if a sheet of glass, larger than the group of flowers, is placed over them, supported on three bent wires, some 6 inches or 8 inches above the ground.

A reference to the issue of *THE GARDEN*, December 16, 1911, will illustrate the sort of wire supports which I find most handy for glasses up to 18 inches by 12 inches.

REGINALD A. MALBY.

THE BEST SAXIFRAGES AND HOW TO GROW THEM.

(Continued from page 449.)

Explanatory.—I find that owing to an inadvertence, my remarks in the third paragraph on page 449 are capable of more than one reading. For example, the genus *Saxifraga* is composed of many sections botanically, though it would be correct to infer that the encrusted, mosses and *Megaseas* do include a larger proportion of species and varieties of greater garden value than the rest. Then, again, it should have been made quite clear that *apiculata*, *rocheli-*

"flat rockery" they are unequalled as carpeters of the soil, and because of a disposition devoid of all fastidiousness. In the sheltered or shaded border, where the best Lilies should find a place, these Mossy Saxifrages might be employed with advantage—anywhere, indeed, where space permitted of an unfettered growth, so that their sheets of blossoms, whether of white or pink or crimson, should be of the picture-making order. Culturally, there are no difficulties in the way, since in autumn or spring the plants may be pulled to pieces and pricked out over any required area of ground.

Among the best of the older sorts are *caespitosa* (white), *Camposii* (also known as Wallacei, whose big snowy bells appeal to all), *hirta*, *densa*, *Whitlavii* (white-flowered and unusually compact), with *palmata*, which is the giant of the set and a handsome plant to boot. Of the earlier coloured sorts, *Rhei* (pink), *R. superba* (pink), Guildford Seedling (crimson) and the compact-growing muscoides *atropurpurea* are the best; while of more recent varieties, Red Admiral, R. W. Hosier, H. S. Stokes, Bakeri and bathoniensis are the best of the red-flowered set, with Miss Willmott, Lady Deane, Lady Northcliffe and *Arkwrightii* (white-flowered, or with a slight suffusion of colour on opening). These recent novelties are characterised by exceptional vigour, and, attaining to 1 foot high, are valuable as border plants. All are of the easiest culture. E. H. JENKINS.

(To be continued.)

THE MOUNTAIN AVENS.

THERE are, generally speaking, two kinds of *Dryas*. One is *D. octopetala*, the Mountain Avens, which has beautiful large white flowers with golden centres, which adorns the rocks of our Alps and high European mountains, and which extends its area to the Arctic regions of Asia and North America. It is a dwarf plant, creeping over the soil, and is covered with evergreen, beautiful dentate leaves, deep and shiny green on the upper surface, greyish underneath, and it sometimes covers large places on sunny hills or on stony moraines. We have here at Floraire one single plant, so broad and flat that it covers a space of six square feet! The big white

CROCUS VERSICOLOR, A BEAUTIFUL SPECIES TO PLANT IN THE ROCK GARDEN NOW.

thereof, if further lightened with some well-decayed leaf-soil, seems to suit them admirably, especially if the corms are planted about four inches deep and surrounded by some sharp sand.

It is frequently recommended to plant them much nearer the surface, and while this may be advisable in less well-drained soil than that usually found in the alpine garden, I find it much safer to put them deeper, as there is then less risk of injury in planting other things near them; and when one has a small garden one cannot always devote a special spot to such plants alone, often finding it necessary, and indeed desirable, to mask the otherwise bare patch left by the dormant bulbs later in the season with some other, though more surface-rooting plant, which also serves the double purpose of decorating their site in summer and providing a carpet of foliage through which the welcome flowers may emerge at their flowering-time.

If, as not infrequently happens, we are favoured with a spell of rough weather just as the blossoms are about to open, much damage can be avoided

ana, *sancta* and *scardica obtusa*—all indispensables of a great race—are not of the encrusted set. They embrace with utility a beauty and charm, however, that appeals to all; hence, for convenience, their inclusion with the "best."

Mossy Saxifrages.—These are evergreen, and are characterised by dense cushions of, for the most part, pale green foliage, and, afforded a certain degree of root moisture—some, indeed, are virtually sub-aquatic—or a cool rooting medium in moderately good soil, grow with considerable freedom and great ease. At home in border soil of ordinary richness, or growing freely in the cool, sequestered places of the rock garden, or in others where a liberal root-run is ensured them, they should never be planted on dry banks, where the soil is not only meagre, but poor, or in other positions where in summer-time they would be likely to suffer from heat or drought. As edgings of an informal character to borders of bold herbaceous subjects, in handsome groups on the slightly-raised rockery border, or in spreading masses on the so-called

flowers please us from the beginning of May till the end of November. It likes poor and stony soil and a sunny position, and may be increased by cuttings, layers, or seeds, which it gives in abundance. The other is the yellow-flowered one (*D. Drummondii*), an American species growing all over the North American mountains to the North of Canada; the leaves are greyish green, less deeply cut, and the flowers smaller, nodding and yellow. But two other species are known. One is the American *D. tenella* or *integrifolia*, coming from Gröenland, and has very small, uncut or less dentate leaves and smaller flowers. The other is a Tyrolean plant, growing in the Dolomites, and is called *D. lanata* or *vestita*. Its leaves are smaller, less deeply dentate, and white on both sides; its flowers smaller and more abundant than those of *D. octopetala*. *D. lanata* always bears a mass of flowers. It is much dwarfier than the type, and is the best for the wall garden or for sunny places in the rockery.

Floraire, near Geneva.

H. CORREYON.

GARDENING FOR BEGINNERS.

BEAUTIFUL BEDS OF BULBS.

ONCE more the season has come when lovers of bulbous flowers will be very busy ordering. From No. 1 to No. 5 the designs show a very simple but effective arrangement of bulb-borders for a

own tastes. Nos. 1 1, all crimson Hyacinths; Nos. 2 2 2 2, white Hyacinths. The four corner beds, Nos. 3 3, edged with blue Hyacinths, King of the Blues being a suitable variety. Nos. 4 4, Tulip Keizerskroon, and Nos. 5 5, edgings of Tulip White Joost van Vondel. If white La Grandesse and crimson Roi des Belges Hyacinths are planted in the other beds with King of the Blues, all the bulbs will be in full flower at the same time and make a brilliant display. The pointed border, Nos. 6 to 9, is one that often has to be filled at the end of a shrubby bed, and it may be planted as follows with May-flowering Tulips: No. 6, elegans, scarlet; No. 7, White Swan; No. 8, The Fawn, flushed pink; and No. 9, Picotee, white, crimson edge. No. 10, double Tulips: Toreador, scarlet, terra-cotta edge; No. 11, The Queen, white, yellow base. A round bed is suitable for any position. The other large bed is well adapted for corners of lawns or for lawns of irregular shape. No. 12 may be filled with Tulip Keizerskroon, and No. 13 with Tulip White Joost van Vondel. Long, narrow borders are also numerous. They are often formed near paths, and rows of distinct colours look well in such. No. 14, Hyacinths: Grand Maître, medium blue; No. 15, gigantea, pink blush; No. 16, L'Innocence, white; and No. 17, King of the Blues, deep blue. Another narrow border, such as the one shown, Nos. 18 and 19, may be planted with Jonquils, Campenelle in the centre, yellow; and No. 19 the Silver Jonquil, which has silvery white flowers. G. G.

1.—PLANS FOR FORMAL BEDS OF BULBS.

the bulbs, preparing the soil and deciding as to the various designs which shall be carried out. Heavy, firm bulbs, consistent with size, are the best. They generally bear one main spike in the case of Hyacinths, and keep fresh for a considerable time when in flower. Very large bulbs of Narcissi, Snowdrops and a few others produce more than one stem of flowers, so that due allowance must be made as regards the distance apart at planting-time. If Narcissi are very much crowded, the foliage and flowers will need very careful staking to prevent them falling apart and lying on the soil.

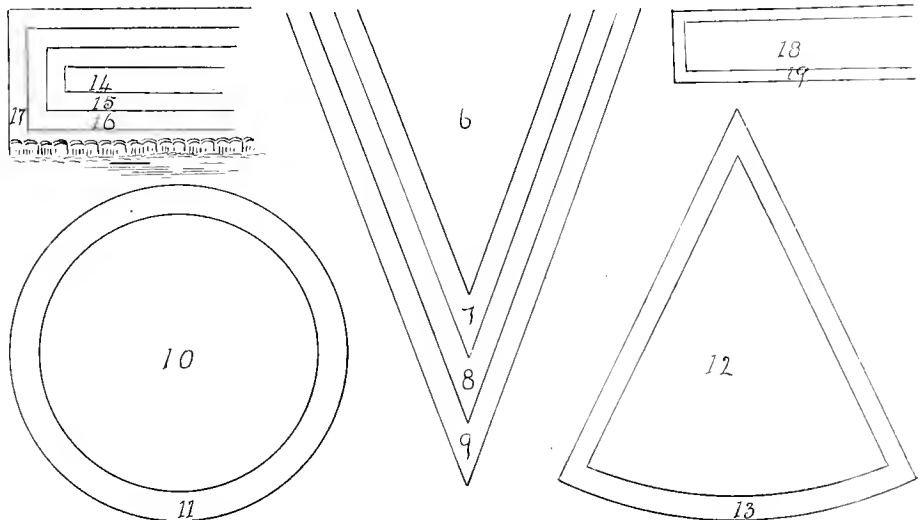

Preparing the Soil.—A deep, sandy loam is the best for bulbs to grow in. Where such obtains, very little preparation is needed beyond the deep digging of the soil and the addition to it of some well-rotted manure. If it is of a clayey or retentive nature, deep digging is advisable, also a slight raising of the beds. Where old potting compost is available, some of it should be mixed with the original soil, and road grit freely incorporated with it also improves the whole as a rooting medium for bulbs. Fresh manure must never be used. Even if the soil is poor in quality it would be better to be content to deeply work it and not put any manure in. All suitable manure must be well mixed with the soil a little below the layer of soil in which the bulbs will be planted, so that the roots of the latter will come into contact with it later on and at a stage of growth when some stimulating food is required.

The Plans and the Planting.—Any of the plans may be utilised separately, if necessary, where only one bed is required to be planted with bulbs.

small or medium-sized garden. The arrangement is a formal one, and bulbs only are to be planted (not bulbs and other kinds of plants associated; a set of such borders will be given in due course), so that they will be quite in keeping. Bold planting is the best. Mixed colours may be used in a bed, but each bed or portion of it planted with separate distinct colours looks the most pleasing. The following are given as examples, but readers may vary them, of course, to suit their

AUTUMN TREATMENT OF PRIMULA SINENSIS.

UNTIL a few years ago, I, in common with many other cultivators of these pretty winter and spring flowering plants, thought that a rather high temperature was necessary in order to grow them really well. A high temperature is not needed. I have had plants in a greenhouse covered with sheets of paper during severe frosts, and have seen water frozen on the paper, but the plants were not damaged in the least. B.

2.—PLANS FOR CORNER AND NARROW BEDS ON LAWNS.

GARDENING OF THE WEEK.

FOR SOUTHERN GARDENS.

The Flower Garden.

The Herbaceous Borders.—Every effort should be made to maintain these in as attractive a manner as possible by removing the growths of the earlier-flowering subjects, not entirely to the ground, but shortening back and thinning where necessary, so that they do not hide the more showy plants. Attend to the proper supporting of autumn-flowering Chrysanthemums, Asters (Michaelmas Daisies) and the taller-growing plants, such as Eupatorium purpureum, Artemisia lactiflora (a good plant), Rudbeckia nitida, R. Herbstone, Helianthemum autumnale superbum, Solidago and others.

Gypsophila paniculata.—It may not be generally known that if the inflorescences of this plant (particularly the single one in question) are cut when dry, they may be used the winter through with good effect associated with the many varieties of Everlasting Flowers. These and the varieties of ornamental Grasses should be cut and bunched, and suspended head downwards to dry before the advent of bad weather.

Michaelmas Daisies.—Never have I seen these, and particularly the border devoted to them entirely, look better at this season of the year. The weather has evidently suited them, and the plants are particularly healthy and free from mildew. Should signs of this pest appear, however, spray with a suitable insecticide.

Agapanthus.—These are generally cultivated in pots, and they are especially beautiful when in flower for standing on terraces or near the entrance to the house. If the stock permits, a plant may be tried out of doors, selecting a warm, open position, and give plenty of good loam and decayed manure in addition.

The Rock Garden.

Hardy Cyclamen.—Any time during the next month or six weeks is the best suited for planting the hardy varieties of Cyclamen, and if to be planted on the rockery a sheltered site should be chosen for them, so that the flowers may be protected in the early spring. Where these grow freely under trees and become naturalised, forming large corms, they are indeed a beautiful sight. For the alpine-house they may be potted now in pots or pans, well drained, using a compost of fibrous loam, with plenty of leaf-mould and a little peat incorporated, and coarse road grit. Avoid deep planting, plunge the pots or pans up to the rims in ashes, and shield from heavy rains.

Iris.—The early-flowering species, such as *I. bakeriana*, *Danfordia*, the varieties of *I. pumila*, *I. histrio* and *I. histrioides major*, should be planted as soon as possible, choosing for them well-drained positions and a porous, sandy soil where the maximum amount of sunshine may reach them when in flower.

The Rose Garden.

Cuttings of many of the Roses, especially the climbing varieties, may now be made and inserted in the open ground that has been well dug and a good sprinkling of coarse sand added. These may be dibbled in, or shallow trenches taken out and the cuttings laid in, 3 inches to 4 inches apart, selecting ripened shoots and making them about eight inches long. Many of the Hybrid Perpetuals, and Teas may be increased in the same way, and will make good plants on their own roots.

Plants Under Glass.

Cinerarias.—Excepting, perhaps, for a day or two after potting, when they may be kept rather closer and shaded, this plant enjoys plenty of air and shade from bright sunshine, and if a cool treatment is afforded, sturdy plants will result that will flower well. When firmly established, they will grow remarkably well if stood on boards or battens under a north wall. The Cineraria is liable to attacks of aphid, which will, if allowed to go on unchecked, quickly disfigure the plants. Water, especially to newly-potted plants, needs to be carefully applied. Keep the plants well syringed and the surroundings moist, especially during warm weather. Avoid overcrowding, and apply a dusting of soot round about the base of the plants, which will help to ward off slugs.

Bulbs in Bowls.—The practice of growing bulbs in fibre has immensely increased in popularity, and the method has much to recommend it, particularly as the whole of the growth can be watched, and from beginning to end the system is cleanly in working. The early-flowering subjects, such as Paper-White Narcissus, Roman Hyacinths, early Daffodils that force with ease and the Duc Van Thol Tulips, should be placed in the fibre at once. Put some large pieces of good charcoal in the bottom; then sufficient fibre for the bulbs to rest upon, so that the tops are within an inch of the rim. Place closely together and fill in firmly with more fibre, just covering over the bulbs. Give a good watering with a rosed can and place away in a cool, dark place until growth has commenced and plenty of roots have formed, when they can be brought out into the rooms, avoiding too bright a position for a day or two.

Fruits Under Glass.

Late Melons.—The weather of late has been most unfavourable for the growth of these. To be successful artificial heat is necessary, and damping down, accordingly, must be attended to, otherwise red spider will be almost sure to attack the foliage. Syringing in dull weather must not be too heavy, otherwise the foliage will become weakened. Air should be admitted, if only for an hour or so, on all favourable occasions, and, when the fruits are swelling, close the house early in the afternoon and take advantage of the solar rays. See that the border does not suffer for the want of water, and give periodical applications of manure-water. When the fruits attain sufficient size, attend to their support by means of nets, thin square boards or other device. By all means have the roof glass outside thoroughly clean, so that the maximum amount of light can reach them.

Earliest Vines.—The earliest-forced Vines that were started prior to the New Year will by now have ripened sufficiently to admit of the shortening back of the wood, which will allow the basal buds to plump up and become better ripened. Where plants have to be accommodated, this is also a great advantage, as it prevents them becoming drawn, and, providing it is not done too early, no harm will accrue. E. BECKETT, V.M.H.

Aldenham House Gardens, Elstree, Herts.

FOR NORTHERN GARDENS.

The Flower Garden.

Carnations.—The planting of beds should be no longer delayed, in order that the plants may be properly established before winter. It is as great a mistake to plant outdoor Carnations deeply as it is to pot them deeply. Place a short stick to the stronger plants, which will prevent them from being twisted about by high winds. A portion should be potted to make up blanks and to plant in groups in mixed borders in early spring. If strong plants, they will each require a 4-inch pot to do them justice. Place the plants where they can be protected from rain, moisture being the means of loss beyond anything else, unless it be rats, which are extremely fond of the plants.

Asters.—The tall species may now or soon be spread out to fill up spaces in front of them made by earlier-flowering plants. Such as *linifolia* (acris), many kinds of *Novi-Belgi*, *Beauty of Colwall*, *amethystinus* and other loose-habited kinds conform splendidly to this treatment, and they look very much better than tightly tied to sticks, however necessary these may be.

The Rock Garden.

Planting.—Any plants to be introduced before winter should be put in without delay, in order that the new roots may obtain a grip of the soil before winter sets in. There is no doubt that a plant established in autumn has a tremendous advantage over one reserved till spring, in some cases the latter not blooming till a year has passed, the Eastern *Meconopsis Wallichii* and *M. integrifolia*, for instance. Early-flowering Primulas should also be planted at once.

Gentiana.—One of the prettiest flowers at this season is *G. Pneumonanthe alba*, which is much to be preferred to the type, one of the rare

instances where a blue-flowered species is less charming than a white derivative. Though common, *G. acaulis* is perhaps unapproached by any other when massed. If left to grow too thick, it, however, fails to flower freely, and every few years should be lifted, divided into small clumps and be replanted a few inches apart. It does best in heavy soil, but with the aid of rotted manure and making the soil very firm it seems to succeed under very opposite conditions. Sunshine is essential at the flowering period.

The Plant-Houses.

Dutch Bulbs.—A batch of Tulips and Hyacinths for early flowering should be potted forthwith, well watered and stood in a cold frame till wanted. The whole of the Narcissi not yet in pots should be potted without further delay. *Telamonius plenus* does very well in 5-inch pots, as many bulbs as can be got in; but the stronger-growing *Sir Watkin*, *Emperor* and others of that type give the best results when 7-inch or 8-inch pots are used, also grouping the bulbs close together. Moisture is essential, and means should be taken to ensure that the soil never becomes dry.

Begonias.—Tuberous varieties in greenhouses are apt to go off at the base of the growths when a spell of cold weather sets in. Careful watering, with a circulation of slightly-warmed air during wet and cold weather, delays the stoppage of growth. Such plants should be stored away in a cool frost-proof place for the winter and not be watered. Plants of *B. Gloire de Lorraine* to flower next month and later must now be permitted to grow unchecked. If there are too many weak shoots in the body of the plants, thin them out to the stronges, and there will be a more extended and a superior lot of bloom. Weak manure-water is a great help, and an occasional vaporising with nicotine is imperative to keep down mite.

The Vegetable Garden.

Onions.—In many instances the crop is ready to lift, it being better to harvest the crop before the foliage has quite decayed than to leave it to be excited to renewed root action by autumnal rains. If there is no means of drying on the ground, the bulbs should be spread out on wooden trellises, or on coarse wire-netting raised above the ground, and left till the bulbs are quite hard, the foliage being removed as it becomes matured.

Celery.—An opportunity may be taken to tie all the advanced heads with a piece of soft bast, breaking off any root growths at the same time. This saves trouble later, when it is difficult sometimes to get weather suitable for working the trenches. If needed, some more may have earth placed about the plants, though there is no need to apply as much as is essential later. Make it rather firm to keep it from becoming sodden with heavy rains.

Parsley.—Lift plants that have been transplanted and grown singly throughout the summer, placing them where they cannot be damaged by intense frost. A late Peach-house suits very well, the plants being put on the surface of the border, and soil or leaf-mould placed about the roots so as to keep them moist and partially active through the winter months. Choose small plants rather than large ones.

The Fruit Garden.

Vines.—Those which are now clear of bunches should be, as far as possible, freed from all parasitic insects. Syringing, or, better still, spraying with hot water often repeated is good. Vaporising with nicotine is also a valuable aid, but hydrocyanic acid is probably the best insect dispeller at the command of the grower. If the ventilators are kept closed twelve hours or so subsequent to the application, 10z. of cyanide of potassium, 20z. of sulphuric acid and 40z. or more of water will be effective, and is harmless to the foliage.

Strawberries.—The planting of a new quarter should be gone on with, lifting the runners, if they have not been previously laid in, with nice little balls of soil, scattering a little fruit manure at each station to be mixed with the earth in planting, and if the soil is in good condition, firming it about the roots. Hoe the ground nicely after planting is finished. Those planted six or seven weeks ago should have all runners removed, the ground hoed, and a half-inch layer of rotted manure and soot spread evenly over all the bed.

THE FRUIT GARDEN.

APPLE PADNALL SEEDLING.

THIS new culinary Apple was briefly referred to on page 455 of our issue for last week. Since seeing the fruits exhibited at the Royal Horticultural Society's meeting on the 27th ult., when it gained an award of merit, we have visited Padnall Hall, Chadwell Heath, and through the courtesy of Mr. Roberts, who owns the Apple, have seen the trees whence the fruits were gathered. The original tree stands some twenty feet high, and was carrying a very heavy crop of fruit. Several young trees which have been grafted on the Paradise stock were bearing some exceptionally large fruits, and it is evidently a very free cropper. Mr. Roberts informed us that fruits can be used the first week in July, and are in season from then onwards until mid-September. The flesh is firm and of brisk flavour, and the fruits cook exceptionally well. The leafage is very large, and both this and the habit remind us very much of Peasgood's Nonsuch. The fruits, however, are nothing like those of that variety, but to some extent resemble Warner's King.

and warmer soils than yours they are frequently planted in September or October, and give little or no trouble. The Scabious, of course, is different, and though savouring of the perennial, with protection is insufficiently hardy for general purposes when left in the open, hence is much best if treated as an annual and sown in spring. If you desire to retain the Antirrhinums in the border, the plants should not be cut down, but merely shortened back and given a mulch of ashes, fibre, or light litter about the base. Delphiniums, Pyrethrums and Potentillas are perfectly hardy without protection, though a mulch of litter to the border would do good. The Sweet William would be best treated as a hardy biennial, sowing seeds in May and June and transplanting the seedlings each year in September or October.

ROSE GARDEN.

CRIMSON ROSES FOR BEDDING (E. A. Z.).—We think you could not do better than plant General Jacquemont as the Hybrid Perpetual variety, and General Macarthur as the Hybrid Tea. We do not consider the colours of Gustav Gruerwald and Lyon Rose would clash.

POT ROSES IN COLD FRAME (E. A. Z.).—It would have been better had you kept the plants nearer the glass; but you could prevent them being spindly by putting three or four sticks around the side of the pots and tying the growths to them. You can then bend the shoots out to any desired shape, and this will encourage basal eyes to start out.

MALFORMED ROSE-BUDS (Mary Mazze).—The buds seem to be those of a hard opening variety. Unfortunately, many Roses that expand freely in France are totally unfitted for our climate. We would advise you to adhere more to British-grown plants, and also to varieties raised in England or Ireland. Of course, we are indebted to our

common agricultural treacle, stir well and add ten gallons of water. The wash will then be ready to use.
